Summary

The bewildering diversity of brain neurons arises from relatively few pluripotent progenitors through poorly understood mechanisms. The cerebellum is an attractive model to investigate mechanisms of neuronal diversification because the different subtypes of excitatory and inhibitory neurons are well described [1,2]. The cerebellum is a hub for control of motor function and contributes to a number of higher brain functions such as reward-related cognitive processes [3]. Deficits in cerebellar development lead to severe neurological disorders such as cerebellar ataxias [4] and medulloblastomas [5], a heterogeneous and severe groups of childhood brain tumors, thus underlying the importance of understanding the cellular and molecular control of cerebellar development. In contrast to text book models, we report that excitatory and inhibitory cerebellar neurons derive from the same pluripotent embryonic cerebellar stem cells (eCSC). We find that the excitatory versus inhibitory fate decision of a progenitor is regulated by Notch signaling, whereby the cell with lower Notch activity adopts the excitatory fate, while the cell with higher Notch activity adopts the inhibitory fate. Thus, Notch-mediated binary cell fate choice is a conserved strategy for generating neuronal diversity from common progenitors that is deployed at different developmental time points in a context specific manner.

32 **Body text**

33 ***Cerebellar anlagen***

34 Text book models suggest that different cerebellar neurons arise from two distinct progenitor
35 pools (Fig.S1A) located either dorsally in the rhombic lip (RL) or ventrally in the ventricular
36 zone (VZ). Two basic helix-loop-helix (bHLH) transcription factors called Atonal homologue
37 1 (Atoh1; RL) and Pancreas transcription factor 1 alpha (Ptf1a; VZ), mark these progenitors.
38 Atoh1^{+} RL progenitors give rise to glutamatergic neurons, while Ptf1a^{+} VZ progenitors give
39 rise to GABAergic neurons [6]. However, pseudo-time trajectory analysis of single-cell RNAseq
40 (scRNAseq) embryonic mouse cerebellum data suggests that a common pool of progenitors
41 branches into either a glutamatergic fate or a GABAergic fate [7]. In addition, cell fate in the two
42 germinal niches can be switched when Atoh1 and Ptf1a are ectopically expressed in the VZ
43 and RL, respectively [8,9]. Finally, the classic neural stem cell marker Sox2 is an early VZ marker,
44 but cells expressing both Sox2 and the RL marker Atoh1 were observed in human cerebellar
45 organoids [10]. Whether this means that common pluripotent progenitors competent to generate
46 both excitatory and inhibitory lineages exist, and how this binary fate decision is regulated, are
47 unknown.

48 ***Characterization and fate mapping of embryonic Cerebellar Stem Cells***

49 We observed Sox2 protein expression in VZ and RL during cerebellar neurogenesis (E9.5 –
50 E16; Fig.1SB-F). Furthermore, some Sox2^{+} cells express Atoh1 (Fig.1SB'-F'). This suggests
51 that Sox2^{+} progenitors may represent a pool of eCSCs generating both excitatory and inhibitory
52 lineages. To test this, we performed lineage tracing in
53 *Sox2^{CreERT2}/Gt(ROSA)26Sor^{tdTomato}/Atoh1^{GFP}* mice using low doses of Tamoxifen (TM: 0.1mg,
54 0.03mg). Under both conditions, in all mice examined, Sox2^{+} cells and their progeny labelled
55 with tdTomato (tdTomato+). We observed Ptf1a^{+}/tdTomato^{+} and Atoh1^{+}/tdTomato^{+} cells at
56 E12.5 in the VZ and RL, respectively (Fig. 1A-F''). At postnatal day 21 (P21) we found
57 tdTomato^{+} Purkinje cells (PCs, Calbindin^{+}), granule cells (GCs, Pax6^{+}), glutamatergic deep
58 cerebellar nuclei (glu-DCN, Olig2^{+}, Pax6^{+} and Tbr1^{+}) and GABAergic interneurons (INs,
59 Pax2^{+}), suggesting they all come from Sox2^{+} eCSCs (Fig.1G-N and S2).

60 To characterize the progeny of single eCSCs, we employed the sparse clonal Mosaic Analysis
61 with Double Markers (MADM) technology [11,12]. Briefly, depending on how the red and green
62 markers segregate after recombination, the two hemi-lineages of a common progenitor would
63 label either in red versus green or in yellow versus no-label (Fig. 2A). Thus, the presence of

64 rare clones strictly containing either different cell types in the two different colors, or only one
65 cell type in yellow, is consistent with recombination in a common progenitor. More importantly,
66 failure to find such clones indicates lack of common progenitors. Consistent with sparsity of
67 MADM clones [11,12], TAM injection at E11 generated an average of 0.42 MADM events per
68 brain (13 in 31 brains). In 2 clusters, we observed GABAergic and glutamatergic cells in
69 different colors, containing GCs, PCs and cerebellar INs (Fig. 2B-G and S3C-F) providing
70 direct evidence for a common progenitor. In 6 clusters, we detected either GABAergic lineages
71 (PCs or INs) or Glutamatergic lineage (GCs) in yellow (Fig. 2H-I and S3G-G''), but not both.
72 In the remaining 5 clusters, sparse green or red GABAergic lineages were observed (Fig. S3A-
73 B), indicating recombination occurred in fate-restricted precursors. Consistent with the fact
74 that GC precursors undergo transient amplification before neurogenesis, while PC precursors
75 do not, all MADM clones contained more GCs than PCs. We asked if pluripotent eCSC are
76 present in human. We sparsely labelled Sox2$^+$ eCSCs by electroporating Sox2Cre/Venus
77 vectors into human-iPS-derived cerebellar organoids and traced their fate after 16 days in
78 culture. In each organoid, we observed both PCs (Venus$^+$/Calbindin$^+$) and GCs (Venus$^+$/Pax6$^+$)
79 (Fig. 2J-O'''). Altogether, lineage tracing data show that Sox2$^+$ eCSCs give rise to two lineage-
80 restricted precursors that generate both GCs and PCs.

81 ***Notch signaling regulates the fate of embryonic Cerebellar Stem Cells and their progeny***

82 To identify the molecular underpinnings of the diversification of cerebellar neurons from
83 common progenitors, we analyzed available scRNAseq data from E10-E13 mouse cerebella
84 (ENA: PRJEB23051 [13]) to define the molecular features of eCSCs and their derivatives (Fig.
85 S4A). We identified individual clusters and mapped pseudo-time trajectory for cerebellar
86 lineages (Fig. S4B-D and 3A). scRNAseq analyses suggest that Sox2$^+$ progenitors split into
87 two major lineages: glutamatergic cells from RL and GABAergic cells from VZ, in agreement
88 with lineage tracing (Fig. 3A).

89 In the *Drosophila* brain, neural progenitors give rise to daughter cells that adopt alternative
90 fates via the Notch pathway [14]. In the mammalian brain, Notch activity is crucial for
91 maintaining neural progenitor state and inhibiting neurogenesis [15] but there is no evidence that
92 neural stem cells use Notch to generate neuronal diversity. We asked whether the expression
93 of Notch pathway genes correlates with cell fate in cerebellar scRNAseq data. We found that
94 Sox2$^+$ progenitors have the highest level of Notch activity, followed by Ptf1a$^+$ VZ precursors,
95 while Atoh1$^+$ RL precursors have the lowest levels of Notch activity, but the highest levels of

Notch ligands Dll1 and Dll3 (Fig.3A, S4E-F, S4I-J, S4N-O, S4K-M, S4P-R and Table 2). This suggests that Notch activity may play a role in successive fate decisions of eCSC: first to segregate eCSCs from their fate-restricted daughters, and then Ptf1a^{+} PC precursors from Atoh1^{+} GC precursors.

To test this, we first created Notch gain of function (GOF) eCSC clones using *Sox2*$^{CreERT2/+}$/ *Gt(ROSA)26Sor*^{tdTomato}/*R26R*$^{stop\text{-}NICD\text{-}nGFP}$ mice. While both Ptf1a^{+} and Atoh1^{+} precursors were significantly reduced, quantification showed that the effect was stronger on Atoh1^{+} cells than on Ptf1a^{+} cells (Fig. 3B-J and S5C-G). Conversely, Notch GOF significantly increased Sox2^{+} eCSCs in the RL and VZ (Fig. 3M-Q, S5E-F'' and S5H), at the expense of both Ptf1a^{+} and Atoh1^{+} cells. Thus, constitutive activation of Notch in eCSCs inhibits differentiation into both excitatory and inhibitory fates and retains cells in a Sox2^{+}/Notch^{HIGH} eCSC state.

Next, we asked whether the choice between Ptf1a^{+} and Atoh1^{+} cells requires Notch signaling. We examined Notch loss of function (LOF) either in clones using *Sox2*^{CreERT2}/*Notch1*^{flox}/*Atoh1*^{GFP} conditional knockout (KO) mice, or in Presenilin1 KO (Psn1) mice, which have a near-complete loss of Notch activity. Notch1 ablation in eCSC clones increased the number of Sox2^{+}/Atoh1-GFP^{+} double positive cells and Atoh1^{+} cells could now be found in the VZ (Fig. 4A-D), indicating Notch LOF induces Sox2^{+} cells to differentiate into Atoh1^{+} precursors. The increase in Atoh1^{+} cells came at the expense of Ptf1a^{+} cells which were significantly decreased in Notch1 LOF eCSC clones (Fig. 4E-G) as well as Psn1 KO mice (Fig. 4H-J, S7A-B). Importantly, the ratio of the increase in Atoh1^{+} cells was nearly identical to the ratio of decrease in Ptf1a^{+} cells (0.672 vs 0.673, Fig. 4G, J). Furthermore, whereas wild type cerebellar precursors rarely co-express Atoh1 and Ptf1a [8], there was a dramatic increase in Ptf1a^{+}/Atoh1^{+} double positive cells under Notch inactivation conditions (Fig. S6), suggesting a failure in resolving cell fate. Lineage tracing suggested that other types of GABAergic VZ precursors also derive from Sox2^{+} eCSCs. We examined the expression of other VZ precursor markers, namely Olig2, which maintains the identity of PC progenitors [16], and Lhx1/5, a marker for early GABAergic cells, in Psn KO mice and found that both were decreased, concomitantly with the increase in the number of Atoh1^{+} cells (Fig. S7C and S7D-H). Therefore, Notch activity regulates the choice of eCSC progeny between excitatory and inhibitory precursor fate.

128 ***Discussion***

129 In *Drosophila* neuronal lineages, the two daughter neurons of the same precursor use Notch to
130 adopt different identities during terminal cell division [17–19]. Similarly, spinal cord inhibitory
131 interneurons use Notch activity to adopt different identities [20]. Single cell analysis in the
132 neocortex is beginning to reveal significant diversity of excitatory neuronal fates in the same
133 cortical layers [21]. It would be interesting to test whether Notch signaling is also used to
134 distinguish the fate of excitatory cortical neurons, where paucity of markers may have
135 precluded such findings.

136 In contrast to text book models, we show that mouse and human cerebellar GABAergic and
137 glutamatergic neurons derive form common progenitors, which we term embryonic Cerebellar
138 Stem Cells. Although we mainly focused on PCs and GCs, lineage tracing showed that eCSCs
139 likely give rise to most cerebellar cells. eCSCs span the RL and the VZ and are characterized
140 by the expression of $Sox2^{+}$ and high levels of Notch activity. We thus provide mechanistic
141 evidence for how common progenitors can generate both excitatory and inhibitory lineages in
142 the mammalian brain. It will be interesting to test whether Notch activity in eCSCs or their
143 daughters may play a role in disorders of cell fate or stem cell behavior such as
144 medulloblastomas.

Fig. S2 Tracing of INs and DCN lineages in the cerebellum

(A) Scheme of the experiments. Pregnant females were injected Tamoxifen at E9.5 or E10.5 through intraperitoneal (i.p.), and the samples were collected at E15 or P21, followed by immunostaining. (B-C) Co-localization of $Pax2^+$ (green, a marker for INs) and Tom^+ (red) in cerebellar primordium at E15. (D-D'') Higher magnification of the rectangular region in (C). (E-F) Co-localization of $Pax2^+$ (green) and Tom^+ (red) at P21. (G-G'') Higher magnification of the rectangular region in (F). (H-I) Co-localization of $Olig2^+$ (green, a marker for glu-DCN) and Tom^+ (red) at E15. (J-J'') Higher magnification of the rectangular region in (I). (K-L) Triple immunolabeling with Tom (red), Pax6 (grey) and Tbr1 (green, a marker for glu-DCN) at E15. (M-N) Higher magnification of the rectangular region in (L). Nuclei were stained with DAPI (blue). Arrows indicate double positive cells of Tom^+ with $Pax2^+$ or $Olig2^+$ or $Pax6^+$ or $Tbr1^+$. Scalebars=100 μm and 25 μm.

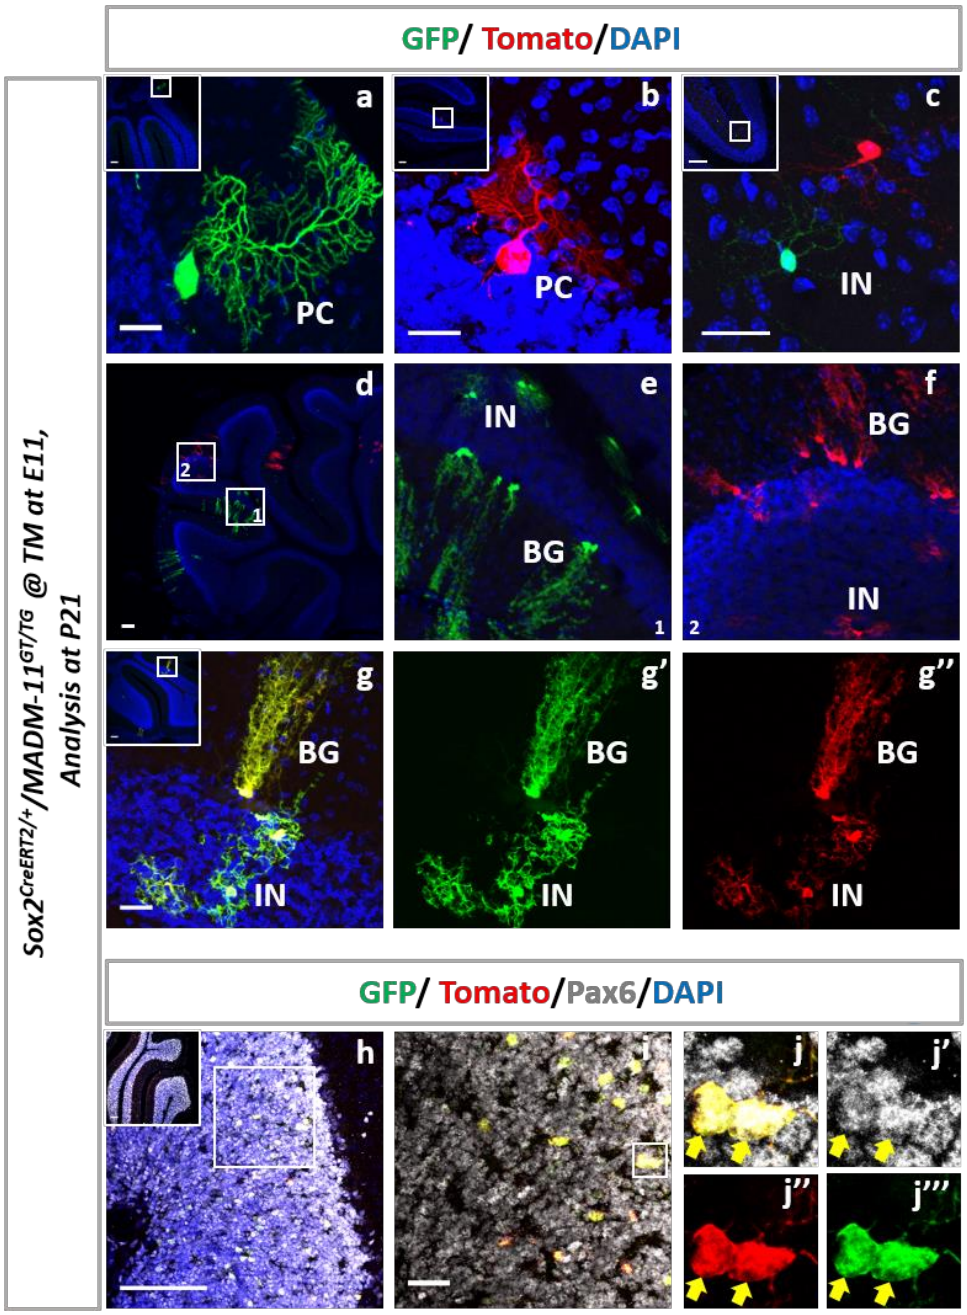

Fig. S3 Tracing of cerebellar lineages using MADM

(A-F) Sparse G2-X MADM labeling cells in P21 cerebellum. Two PCs (red and green), several Interneurons (Ins, green and red) and Bergmann glia were found in different mouse cerebella. (G-G'') Sparse G2-Z MADM labeling cells in P21 cerebellum. Several yellow INs and Bergmann glia were found in mouse cerebella. (H-I) Immunostaining for Pax6, a marker for GCs, at P21. (J-J''') Higher magnification of the rectangular region in (E). Nuclei were stained with DAPI (blue). Scalebars=100 μm and 25 μm.

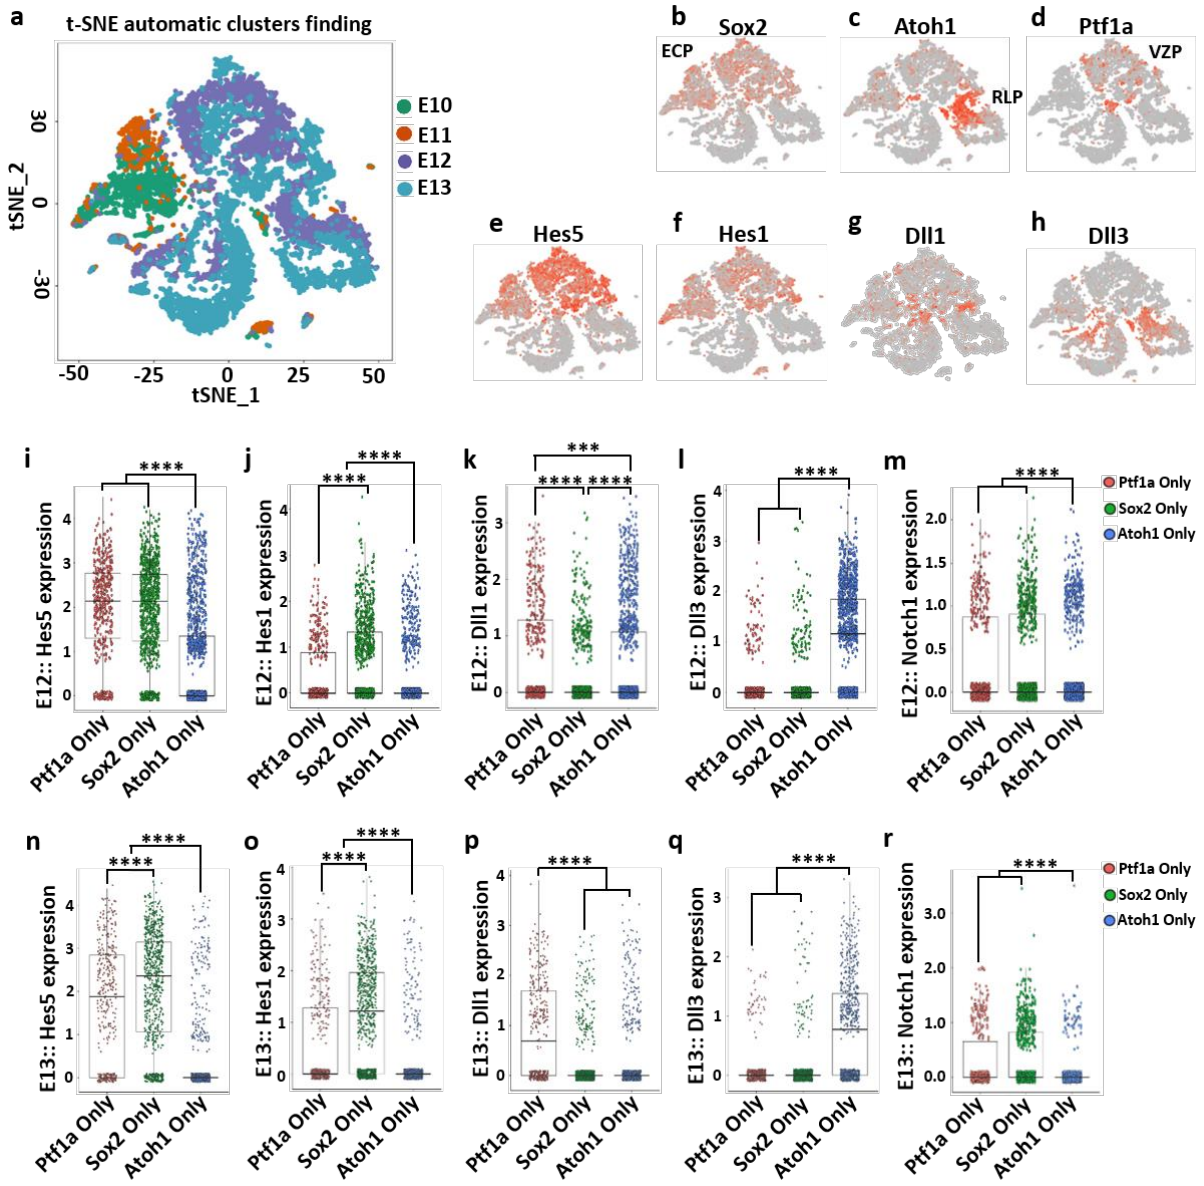

Fig. S4 Analysis of Notch signaling gene expression in scRNAseq data from embryonic cerebellar progenitors

(A) t-distributed stochastic neighbor embedding (t-SNE) visualizations of cerebellar derived cell clusters (right) and developmental time points (left) at E10-E13. Each point represents one cell. (B-D) t-SNE shows cell type specific markers expression: Sox2, Atoh1 and Ptf1a. ECPs, Embryonic Cerebellar Progenitors; RLP, rhombic lip progenitors; VZP, ventricular zone progenitors. Cells are color-coded according to genes expression. (E-H) t-SNE shows Notch signaling related genes expression: Hes5, Hes1, Dll1 and Dll3. Cells are color-coded according to genes expression. (I-R) Expression of Hes5, Hes1, Dll1, Dll3 and Notch1 in three different groups: Ptf1a only, Sox2 only and Atoh1 only both at E12 (I-M) and E13 (N-R). Box plot center lines are median. ***$p < 0.001$, ****$p < 0.0001$.

Supplementary Materials for

Generation of neuronal diversity from common progenitors via Notch signaling in the cerebellum

Zhang et al.

Materials and Methods

Mice

All animal experiments in this study were carried out in accordance with animal welfare regulations and have been approved by Ethic Committee and French regulatory authorities of the respective institutes. The *Sox2*^{CreERT2} mice were crossed with *Gt(ROSA)26Sor*^{tdTom} reporter mice, and then crossed with *Atoh1*^{GFP} mice to generate the lineage tracing line. Notch gain-of-function mice were generated by breeding *Sox2*^{CreERT2}/ *Gt(ROSA)26Sor*^{tdTom} with *R26R*$^{stop\text{-}NICD\text{-}nGFP}$ (JAX, stock #008159, borrowed from Shahragim TAJBAKHSH lab)[22]. Presenilin1 deficient (*Psn*$^{-/-}$) mice (borrowed from Bart De Strooper) crossed with *Atoh1*^{GFP} mice to get *Atoh1*^{GFP}/*Psn*$^{-/-}$ mice. And Notch conditional knock out mice was generated by crossing *Notch1*^{flox} (purchased from JAX, stock #007181) with *Sox2*^{CreERT2}/ *Atoh1*^{GFP} mice. Mice were genotyped genomic DNA isolated from toe tissue. The primers used for genotyping were shown in table1.

Table 1. Primers for mouse genotyping

266

267 ***Tamoxifen Administration***

268 Tamoxifen (TM, Sigma) or 4-Hydroxytamoxifen (4-OH, Sigma) was dissolved to a final
269 concentration of 1mg/ml or 3mg/ml in 90% corn oil (Sigma) with 10% ethonal (Sigma). For
270 *Sox2*^{CreERT2}*/ Gt(ROSA)26Sor*^{tdTom} */ Atoh1*^{GFP} mice, if collected the samples at embryonic stages,
271 0.1mg TM was intraperitoneal (i.p.) injected into per pregnant female at E9.5 or E10.5. If
272 collected the samples at postnatal stages, each pregnant female was injected 0.03mg TM (i.p.)
273 at E10.5. For *Sox2*^{CreERT2}*/Gt(ROSA)26Sor*^{tdTom}*/R26R*$^{stop\text{-}NICD\text{-}nGFP}$ mice and *Sox2*^{CreERT2}*/*
274 *Notch1*^{flox} mice, 0.1ml 4-OH TM or TM (3mg/ml) was injected into the pregnant females (i.p.)
275 at E8.5, respectively.

276

277 ***RNA extraction and Real time PCR (RT-PCR)***

278 Total RNA was isolated from whole cerebellar tissue samples at E13 using Trizol Reagent
279 (Invitrogen). The RNA concentration was measured by a spectrophotometer (NanDrop1000;
280 Thermo) followed by a reverse transcription process using PrimeScript RT reagent kit (Roche).
281 Real time PCR analysis was performed using SYBR green mix (Roche) and the values were
282 normalized to β-actin values. The primer pairs for different genes are as follows: Atoh1, sense
283 5'-CCCAATGTCGGAGAGCAACC-3' and anti-sense 5'-TCCTCGAAGGCTGGGA

284 AGTG-3'; Ptf1a, sense 5'-TAGACACGCTGC GGCTGCGCTTGGCCATAGGCT

285 ACA-3' and anti-sense 5'-ACAAAGACGCGG CCAACCCGATGTGAG-3'; Olig2, sense 5'-
286 CGCAAGCTCTCCAAGATCG-3' and anti-sense 5'- CTCACCAGTCGCT

287 TCATCTC-3'. β-actin, sense 5'- TCCATCATGAAGTGTGACGT-3' and anti-sense 5'-
288 GAGCAATGATCTTGATCTTCAT -3'. PCR conditions used here were denaturing at 95 °C
289 for 10 s, followed by 40 cycles of 95 °C for 5 s and 60 °C for 30 s. Data were analyzed using
290 the comparative threshold cycle (Ct) method, and results were expressed as fold difference
291 normalized to β-actin.

292

293 ***Immunohistochemistry and antibodies***

294 For the samples collection, embryos before E13.5 were fixed in 2% paraformaldehyde (PFA)
295 in PBS at 4 °C for 2-3 hours, and embryos after E13.5 but before born first were perfused with

296 2% PFA, then post-fixed for 24 hours. Whereas, samples which were collected at postnatal
297 stages, perfused the mice with 1 X PBS, followed by 4% PFA perfusion, and then post-fixed
298 in 4% PFA for another 24 hours. Dehydrated embryos or the whole head in 30% sucrose in 1
299 X PBS overnight (o/n). After all the samples sank into the bottom of the tube, embedded them
300 in OCT compound (TissueTek) and frozen at -20 °C. Sagittal sections were made by cryostat
301 (Leica) at 20 μm and then stored slices at -80 °C. For the immunostaining, sections were fixed
302 with 4% PFA for 10 minutes at room temperature (RT), then blocked with 10% normal donkey
303 or goat serum in 1 X PBS with 0.1% Triton (PBT) for 1 hour at RT followed by 3 times washing
304 in 1 XPBT. Thereafter, these sections were incubated with primary antibodies diluted in 0.1%
305 1 X PBT containing 1% normal donkey or goat serum o/n at 4 °C or 3-4 hours at RT. After 3
306 times washing with 1 X PBT, incubated with appropriate secondary antibodies conjugated with
307 Alexa Fluor 488, Alexa Fluor 555, or Alexa Fluor 647 (1:500, Invitrogen) in 0.1% 1 X PBT
308 containing 1% normal donkey or goat serum for 1-2 hours at RT. Washed with 1 X PBT for 3
309 times, then counterstained the slides with DAPI (1:2000, Sigma) and mounted by using
310 Vectashield (Vector) after rinsing. Antigen retrieval was performed by using 10 mM sodium
311 citrate buffer, pH 6.0, boiled 5 minutes in microwave, and cooled down in RT for about 20
312 minutes for Lhx1/5 and Olig2 staining. Primary antibodies used in this study were rabbit anti-
313 Sox2 (1:500, Millipore, AB5603), rabbit anti-Ptf1a and Rabbit anti-Atoh1 (1:200, a kind gift
314 from Dr. Mikio Hoshino, National Center of Neurology and Psychiatry · Department of
315 Biochemistry and Cellular Biology, Japan), rabbit anti-Calbindin (1:500, Immunostar, 24427),
316 rabbit anti-Pax6 (1:300, Biolegend: PRB-278P), rabbit anti-Pax2 (1:200, Thermo, QE215176),
317 mouse anti-Lhx1/5 (1:100, DSHB, AB_531784), goat anti-Olig2 (1:500, R&D systems,
318 AF2418) and Guinea pig anti-Tbr1 (1:500, Synaptic Systems, 328 005). After staining, images
319 were obtained by using confocal microscope (Olympus FV-1200 or Leica SP8).

320

321 ***Cell counts***

322 Confocal images for single layer scanning of sagittal cerebellar sections were calculated for
323 each developmental stages (E11.5, E12 and E13) after DAPI staining. Each section took the
324 average of the four values that obtained from 4 single layer calculating, which could form a Z
325 stack. And each cerebellar samples counted 6-8 sections that took from the beginning to the
326 end of the cerebellum. All quantifications were done blinded to the genotyping. For each stage

327 littermates were analyzed and all groups of quantifications were carried out from at least 3
328 individuals.

329

330 ***scRNAseq quantification and statistical analyses***

331 Aligned 10X data were retrieved from ENA: PRJEB23051 data set for the following samples:
332 E10, E11, E12 and E13. Umitools has been used to generate gene-cell matrices with the
333 following parameters: --extract-umi-method=tag, --umi-tag UB, --cell-tag CB, --per-gene, --
334 gene-tag GX, --per-cell. Genes not expressed in any cells were removed from considerations,
335 as were all mitochondrial and ribosomal protein genes. To remove likely dead or multiplet cells
336 from downstream analyses, cells were discarded if they had less than 3500 UMIs, greater than
337 15000 UMIs, or were composed of over 10% mitochondrial UMIs. The final dataset was
338 composed of 14637 cells and 18937 genes. Then Seurat bioconductor package v2.3.4[23] has
339 been used to do cell-cell comparison and identify cell types. First, we performed a t-SNE (t-
340 distributed stochastic neighbor embedding) with the first 20 principal components after
341 application of PCA reduction. This allowed us to visualize the grouping of cells and the
342 expression of genes of interest. Expression of cells in 3 populations has been represented with
343 boxplot and differential expression between the 3 populations has been calculated with a Welch
344 two sample t-test procedure.

345 Monocle 2.6.4[24] was used to infer the pseudotime trajectory. As we worked with UMI count
346 data, we assumed that the data were distribued among a negative binomial distribution with
347 fixed variance. The genes that "define progress" were selected using the unserpervised
348 procedure "dpFeature": we first selected genes expressed in at least 5% of all the cells. We then
349 run reduceDimension with tSNE as the reduction method, num_dim=10", norm_method="log"
350 and max_components = 2. Finally cells were clustered with the density peak clustering
351 algorithm by setting P to 2 and Δ to 5 (and skip_rho_sigma = T to facilitate the computation).
352 The top 1000 significantly differentially expressed genes between clusters were selected as the
353 ordering genes. The state 3 where Sox2 is expressed and Atoh1 not expressed was defined as
354 the start of the pseudotime. The seurat FindMarkers function was used to identify the top 10
355 genetic markers of each lineage state's.

356

357

358

359 **MADM Mouse Lines and Maintenance**

360 MADM employs Cre recombinase/loxP-dependent interchromosomal recombination
361 highlighting two scenarios: (i) Recombination occurs in G2 phase of the cell cycle will exhibit
362 X segregation (G2-X MADM clone) which can create two distinctly labelled daughter cell
363 lineages from their common mother progenitor cell; (ii) Recombination occurs in G1 phase or
364 in G2 phase followed by Z segregation (G1/G2-Z MADM clone), one or both daughter cell
365 lineages will be labelled in yellow. Mouse protocols were reviewed by institutional ethics
366 committee and preclinical core facility (PCF) at IST Austria and all breeding and
367 experimentation was performed under a license approved by the Austrian Federal Ministry of
368 Science and Research in accordance with the Austrian and EU animal laws. Mice were
369 maintained and housed in animal facilities with a 12-hour day/night cycle and adequate
370 food/water conditions according to IST Austria institutional regulations. Mouse lines with Chr.
371 11 MADM cassettes (MADM-11^{TG} JAX stock #013751, and MADM-11^{GT} JAX stock
372 #013749), and *Sox2-CreER* (JAX stock #017593) have been described previously [25,26]. All
373 MADM-based analyses were carried out in a mixed C57BL/6J, CD1 genetic background.
374

375 ***Generation of MADM Clones in Cerebellum and Tissue Collection***

376 To induce MADM labeling, *MADM-11$^{GT/GT}$/Sox2^{CreER}* were crossed with *MADM-11$^{TG/TG}$* in
377 order to generate experimental mice *MADM-11$^{GT/TG}$/Sox2^{CreER}*. The day of observed vaginal
378 plug was defined as E0 to monitor gestation days. Pregnant mice were injected i.p. with TM
379 (2-3 mg/pregnant female) (Sigma) dissolved in corn oil (Sigma) at E11 to induce MADM
380 clones. Live embryos were recovered at E18–E19 through cesarean section, fostered, and
381 raised until further analysis. At P21 experimental MADM mice were deeply anesthetized
382 through injection of a ketamine/xylazine/acepromazine solution (65 mg, 13 mg and 2 mg/kg
383 body weight, respectively), and confirmed to be unresponsive through pinching the paw. Mice
384 were perfused transcardially with 4% PFA in phosphate-buffered saline (PBS, pH 7.4). Brains
385 were removed and postfixed o/n at 4°C to ensure complete fixation. Brains were washed with
386 PBS, and cryopreserved with 30% sucrose solution in PBS for approximately 48 hr. Brains
387 were then embedded in Tissue-Tek O.C.T. (Sakura). For the analysis of MADM labeling, 30-
388 45µm sagittal sections were directly and consecutively collected and fixed to superfrost glass
389 slides (Thermo Fisher Scientific). Sections were washed 3 times for 5 min with PBS, followed
390 by staining with the nuclear stain DAPI (Invitrogen). After this step the slides were again

391 washed 3 times with PBS and embedded in mounting medium containing 1,4-
392 diazabicyclooctane (DABCO; Roth) and Mowiol 4-88 (Roth).
393
394 ***Imaging and analysis of MADM-labeled brains***
395 Sections were imaged using an inverted LSM800 confocal microscope (Zeiss) and processed
396 using Zeiss Zen Blue software. Confocal images were analyzed in Photoshop software (Adobe)
397 by manually counting MADM-labeled cells. Cerebellar areas were identified by using the
398 Allen Brain Atlas (http://mouse.brain-map.org/static/atlas).
399
400 ***Cerebellar Organoids labeling and staining***
401 Human iPS cells (iPSCs, ATCC-DYS0100) were maintained in self renewal on a layer of
402 geltrex (Gibco, A14133-01), in E8 Basal Medium (Gibco, A15169-01) supplemented with E8
403 Supplement (50X). iPSC were dissociated with EDTA (Invitrogen) 0.5mM, pH 8.0, for 3
404 minutes incubation, to maintain cell clusters. Cerebellar organoids were culture as described
405 by Muguruma et al and Ishida et al. [10,27], and were electroporated at 25 days of differentiation
406 protocol with 33,3 ug of pGL3_Sox2_Cre and 66,6 ug of pCAG_LSL_Venus_NLS (the 24h
407 experiment) or with 20 ug of pGL3_Sox2_Cre, 20 ug pPBase, 80 ug pCAG_LSL_Venus_NLS
408 (the 16d experiment). Organoids were transferred inside the Electroporation cuvettes (VWR,
409 ECN 732-1136, 2mm) resuspended in Buffer 5 (under patent) and electroporation was
410 performed with the Gene Pulser XcellTM. Organoids were fixed at 26d or 41d of
411 differentiation with 4% PFA, cryoprotected in 20% sucrose and embedded in Frozen Section
412 Compound (Leica, 3801480). Organoids were cryosectioned at 40 µm with Leica CM 1850
413 UV Cryostat. Immunofluorescence staining were performed on glass slides. Blocking and
414 antibody solutions consisted of PBS supplemented with 3% goat serum, 0.3% Triton X-100
415 (Sigma). Primary antibodies were incubated overnight at 4°C and secondary antibodies for 1
416 hour at RT. Primary antibodies used were Chicken anti-GFP (1:2000, abcam, ab13970), Rabbit
417 anti-Sox2 (1:500, abcam, ab97959), Mouse anti-Pax6 (1:100, SantaCruz, sc-53108)and Rabbit
418 anti-Calbindin (1:500, Sigma, c2724-2). Nuclei were stained with 1 µg/ml DAPI (Sigma).
419 Sections and coverslips were mounted with Permanent Mounting Medium.
420
421 ***Statistical analysis***
422 Statistical analyses were performed using GraphPad Prism software (GraphPad Software Inc.,
423 La Jolla, CA, USA). N values refers to independent animals and are detailed in the figure

legends. All data are presented as mean ± SEM. Statistical testing was based on t-tests or one-way ANOVA, followed by Tukey's honest significant test.
