Abstract

Drug discovery targeting SH2 domains (key protein-protein interaction modules) has been hampered by a lack of assay systems evaluating SH2 domain-synthetic ligand binding selectivity to reduce potential off-target effects. Here, we developed SH2*scan*, a high-throughput competition binding assay platform used to quantify ligand-SH2 domain interactions, covering >80% of the target class. This platform can be used to design more selective compounds targeting SH2 domains.

Main

Protein-protein interactions (PPIs) remain a prime target for drug discovery programs, given their importance as key biochemical transducers in deregulated cell signaling pathways, as is the case in inflammatory disorders and cancer[1,2]. SH2 domains, of which there are 120 canonical members found in 110 proteins, are prototypical protein-protein interaction modules which generally recognize phosphotyrosine-containing motifs on their protein binding partners[3–5]. Despite divergent amino acid sequences among SH2 domains, the conserved structure among these PPI modules has been thought to present challenges in the development of highly selective inhibitors of targets in the class[6]. While large scale platforms evaluating SH2 domain-phosphopeptide ligand interactions have been developed[7,8], equivalent systems to study the selectivity of SH2 domain interactions with small molecule inhibitors or targeted protein degraders have yet to be developed. Such systems would be of high value to drug discovery programs targeting SH2 domains, given their potential to identify off-target liabilities for hit-to-lead programs in the early stages of drug development.

Here, we describe a high-throughput, plate-based binding assay platform called SH2*scan*, with 95 wildtype SH2 domain-containing constructs covering a total of 97 SH2 domains (>80% of the target class), as well as 7 mutant STAT SH2 domain-containing constructs (**Extended Data Table 1**). This platform utilizes a competition binding assay principle (**Fig. 1a and 1b**). Multiple binding reactions can be performed in parallel with a dose-response of a given competitor; these data can be plotted, and a dissociation constant (K_D) value can be calculated from the curve fitting for the given protein-ligand interaction.

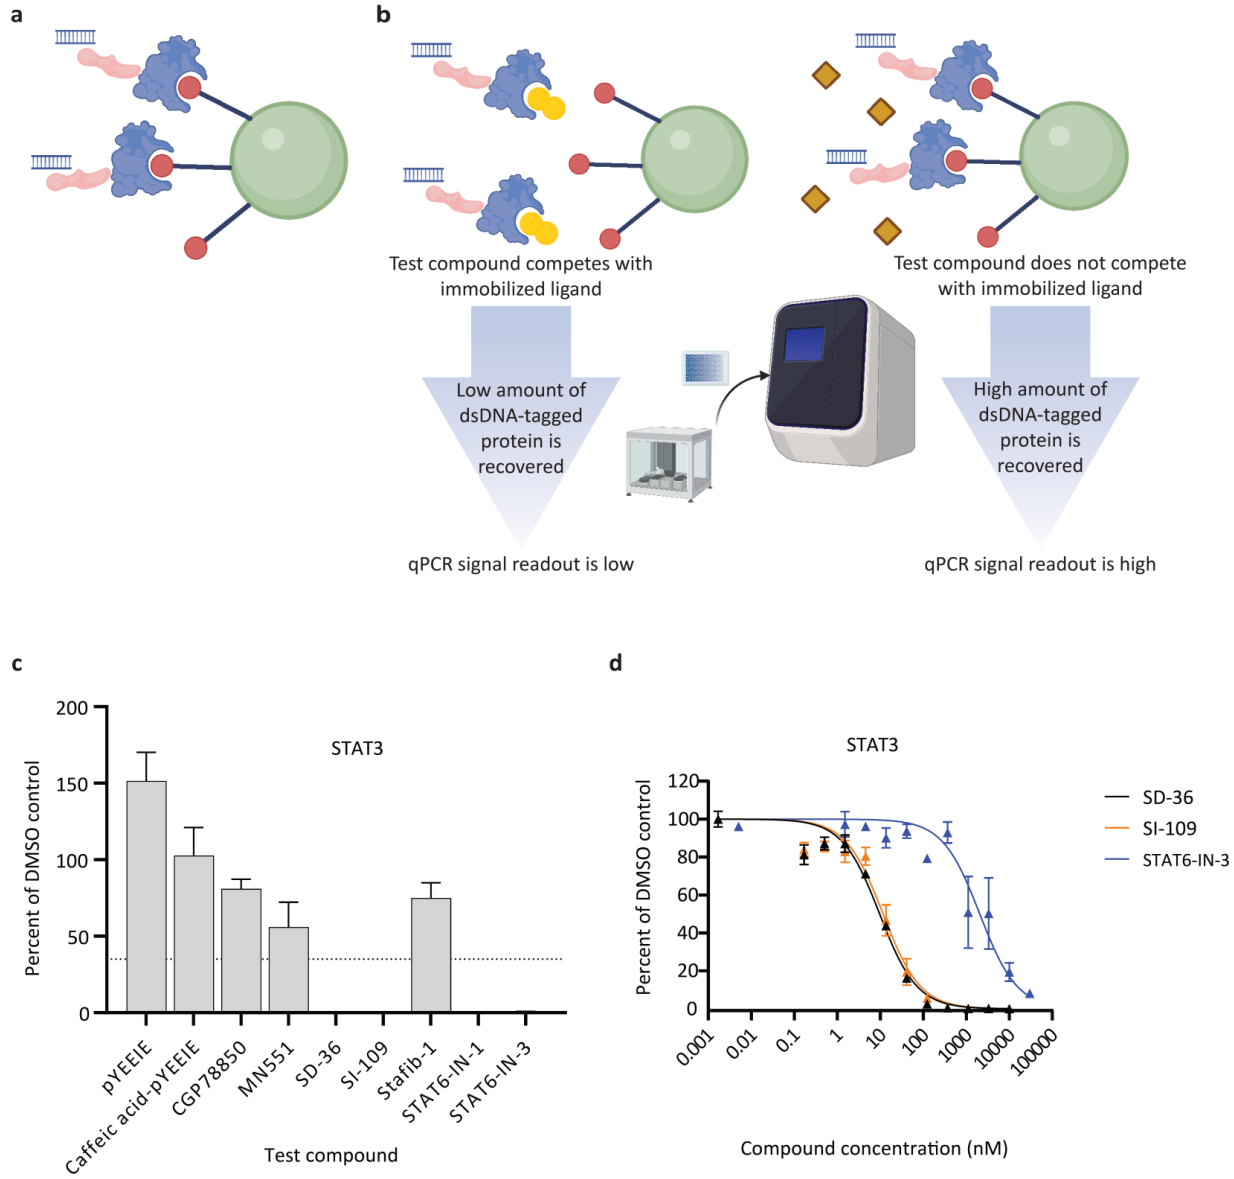

Fig.1|SH2*scan* assay principle for measuring compound dissociation constants. a, An SH2 domain-containing protein construct (blue) fused to the NFκB DNA binding domain (pink) is tagged with an exogenous double-stranded DNA (dsDNA) probe. This construct is incubated with a capture ligand (red) immobilized on magnetic beads (green). **b**, In the presence of a competitor compound (yellow), less tagged protein is captured on the beads. The protein remaining on the beads is eluted using a high concentration of sodium phenyl phosphate, a generic competitor of phosphopeptide binding to SH2 domains[9]. After elution, a lower qPCR signal is obtained at the end of the assay. In the presence of a non-competitor compound ligand (brown), more tagged protein is captured on the beads and a high qPCR signal is observed. **c**, Representative primary screening data for the STAT3 construct are shown. Compounds were tested at 10 µM and the hit cutoff for the compound screen was set at ≤35% of the average signal of the DMSO control wells for each construct (dashed line). Percent assay signal for each compound is expressed as the mean of at least two independent technical replicates from at least one independent experiment, ± standard deviation. **d**, K_D data for selected validated hits for the STAT3

construct are shown. Compounds were tested in dose-response, and the data points were fit to the Hill equation (see Methods). Data are presented as mean percent assay signal from at least four independent technical replicates collected over two independent experiment, ± standard deviation.

To examine the selectivity profiles of synthetic ligands across the SH2 domain target class, we chose 9 compounds from the literature to profile in our panel (**Extended Data Fig. 1**). These compounds were expected to have a range of primary targets based on literature sources and included inhibitors[10–15] and a protein degrader[16]. We profiled each of these compounds in a primary screen and then validated all hits in dose-response to extract K_D values for each protein-ligand interaction. Representative data for the primary screen are shown in **Fig. 1c**, while sample dose-response data are shown in **Fig. 1d**.

A phylogenetic tree was generated containing the 120 *Homo sapiens* SH2 domains, and for each compound, branch tips of the tree were assigned dots proportionally sized to the normalized percent of DMSO signal from the primary screening assay (**Fig. 2**). Hits from the complete primary screen (**Extended Data Tables 2 and 3**) were validated in dose-response to obtain K_D values (**Extended Data Tables 4 and 5**). Available literature values for these interactions are presented in **Extended Data Table 6**. Certain compound-SH2 domain target pairs which were previously described as having measured affinities in the literature[16] that did not come up as hits in the primary screen were tested in dose-response, and in those cases where we measured K_D values, these are indicated in **Extended Data Table 4**. Compounds which were above the hit cutoff in the primary screen that were validated as hits when tested in dose-response, and primary screening hits that did not confirm in the dose-response experiments, are also noted in this table.

We observed a wide range of affinities (picomolar to micromolar K_D values) and selectivity profiles for the compounds tested in SH2*scan*. This study has revealed that even small changes to the chemical structure of SH2 domain-targeting compounds can have profound effects on binding affinity and selectivity within the target class. While some compounds tested showed relatively narrow selectivity profiles (such as SD-36, SI-109 and MN551), others (such as caffeic acid-pYEEIE, STAT6-IN-1 and STAT6-IN-3) showed promiscuity in terms of their SH2 domain binding. These findings demonstrate the utility of compound screening across SH2 domains to reveal off-target binding events.

Many SH2 domain-containing proteins present in SH2*scan* have limited or non-existent biochemical and functional characterization in the scientific literature. This platform can be used to study these targets and potentially uncover new biological insights for them via phosphopeptide profiling. In sum, this work showcases SH2*scan* as an assay platform that can be leveraged at scale to both develop new therapeutics targeting SH2 domains as well as to uncover new protein-protein interaction networks.

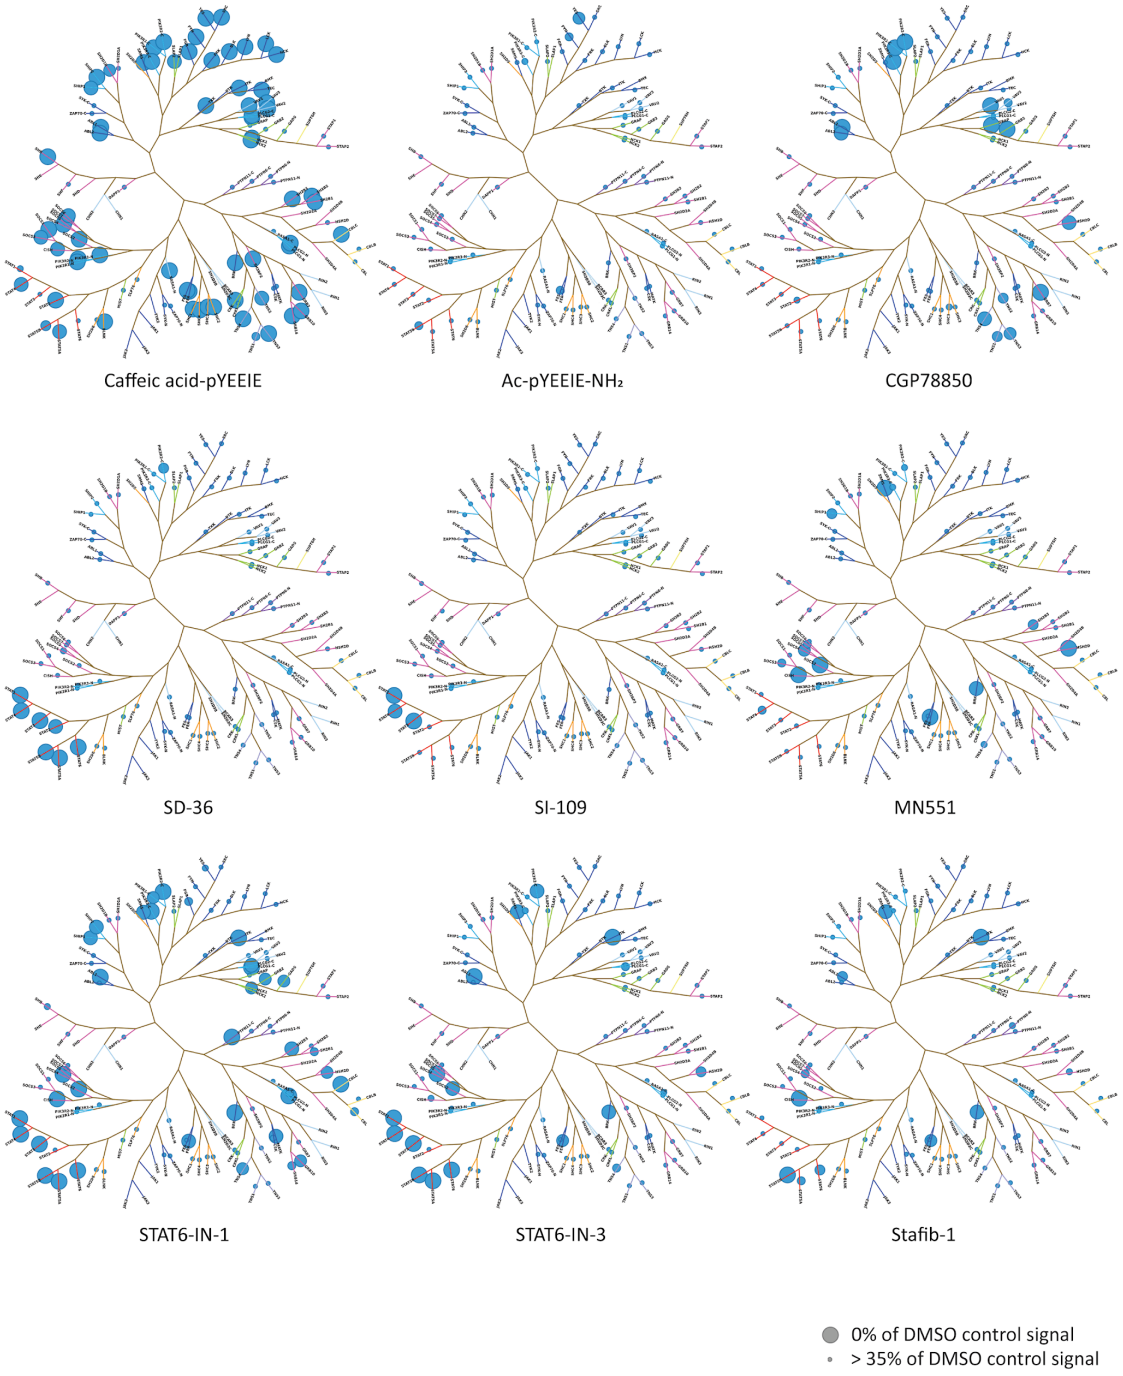

Fig. 2|Primary screening across SH2*scan* reveals unique binding selectivity signatures for synthetic ligands. Percent of DMSO control values were measured for each compound tested in this study and mapped as dots on a phylogenetic tree containing all 120 canonical human SH2 domains. Each dot plotted in a diagram represents a mean value collected from at least two independent technical replicates collected over at least one independent experiment, ± standard deviation. The screening results for the two SH2 domains of SYK and ZAP70 are mapped as equivalently sized dots, given that the SH2 domains for these targets are expressed in tandem constructs, and any competition observed cannot be unequivocally assigned to one or the other SH2 domain.

212 **Online Methods**
213
214 Small molecules and nucleic acids
215
216 Caffeic acid-pYEEIE, CGP78850, MN551, SD-36, SI-109, Stafib-1, STAT6-IN-1, and STAT6-IN-3
217 were purchased from MedChemExpress. The Ac-pYEEIE-NH_2 phosphopeptide was custom synthesized
218 and purchased from Biopeptide Co., Inc. The DNA probe containing the qPCR amplicon for tagging the
219 NFkB fusion domain was custom synthesized and purchased from Thermo Fisher Scientific. The
220 structures of all 9 competitor ligands used in this study are shown in **Extended Data Fig. 1**.
221
222 Protein constructs and protein expression
223
224 Wild-type and mutant SH2-domain containing protein constructs were engineered as N-terminal
225 fusions with the DNA-binding domain of NFkB (amino acids 35–36 fused to amino acids 41–359, with
226 UniProt entry P19838 being used as a reference)[17]. Expression of SH2 domain-containing proteins was
227 achieved through transient transfection of HEK293 cells. The resulting protein extracts were prepared
228 using M-PER extraction buffer (Pierce Biotechnology), with added 150 mM NaCl, 10 mM DTT,
229 cOmplete™ Protease Inhibitor Cocktail (Roche Diagnostics GmbH) and Phosphatase Inhibitor Cocktail Set
230 II (Merck KGaA) according to the manufacturer's guidelines. Phosphatase inhibitors were omitted for the
231 non-phosphorylated (np) STAT3 mutant extracts: np-STAT3(N647I), np-STAT3(S614R), np-STAT3(D661Y),
232 np-STAT3(Y640F), np-STAT3(N567K), and np-STAT3(E616del). These extracts were incubated at 30 °C for
233 45 min during the protein harvest protocol to allow for dephosphorylation of STAT3 phosphotyrosines
234 by endogenous phosphatases. All other extracts for the STAT3 mutant constructs were performed as per
235 the manufacturer's instructions. Construct details are provided in **Extended Data Table 1**.
236
237 Competition binding assays
238
239 Competition binding assays were adapted from protocols used for kinases, bromo domains and
240 KRAS[18–23]. For liganded beads, preparation was performed as follows: streptavidin-coated magnetic
241 beads (Thermo Fisher Scientific) were incubated with biotinylated phosphopeptide capture ligands
242 which were custom synthesized (Biopeptide Co., Inc) at 25 °C for 30 min. In order to remove the
243 unbound affinity ligand and to reduce the nonspecific binding of proteins in the cell lysate, excess biotin
244 (125 mM) was subsequently introduced to the ligand-coated beads. The beads were then washed with a
245 blocking buffer containing SeaBlock (Pierce Biotechnology), 1% BSA and 0.05% Tween 20.
246 The binding reactions were performed with protein extracts containing the DNA-tagged SH2
247 domain-containing construct, affinity ligand-coated beads and a given small molecule test compound in
248 a binding buffer (10 mM HEPES, 50 mM NaCl, 1 mM EDTA, 0.01% Tween 20) in a deep well, natural
249 polypropylene 384-well plate, catalog number 784201 (Greiner Bio-One), in a final volume of 19.7 µL. No
250 purification of SH2 domain-containing constructs was conducted prior to adding the protein extracts to
251 the reaction mixture. The extracts were diluted 10,000-fold in the final reaction, resulting in a DNA-
252 tagged construct concentration of less than 0.1 nM. Binding assay reactions were incubated at 25 °C
253 with shaking for 1 h. After the incubation period, the affinity ligand-coated beads were thoroughly
254 washed with the buffer used in the binding step to remove any non-specifically bound protein from the
255 beads. The remaining bead-bound protein was then eluted from the beads via resuspension and
256 incubation (30 min, 25°C) in an elution buffer of 20 mM sodium phenyl phosphate dibasic hydrate
257 (Sigma-Aldrich) dissolved in the binding buffer. Quantitative PCR was then used to determine the
258 concentration of SH2-domain containing protein constructs in the eluates. Primary screens were
259 conducted using 10 µM of a given test compound. Hits were then validated in dose-response to extract

260 K_D values for each test compound and were determined using a series of 11-point, 3-fold serial dilutions.
261 The concentration of the capture ligand present on the magnetic beads was optimized in each assay to
262 ensure accurate determination of true thermodynamic K_D values for test compounds, as previously
263 described in detail for this type of assay[21]. The complete primary screening data set is shown in
264 **Extended Data Tables 2 and 3**, and the complete dose-response validation data set for this study is
265 presented in **Extended Data Tables 4 and 5**.
266
267 Curve fitting for competitive binding assays
268
269 Thermodynamic dissociation constants (K_Ds) were derived for each competitor-SH2 domain-
270 containing construct interaction by fitting the data to a standard dose-response curve using the Hill
271 equation:
272
273 $\text{response} = \text{background} + (\text{signal} - \text{background})/(1 + (K_D^{\text{Hill slope}}/\text{dose}^{\text{Hill slope}}))$
274
275 The Hill slope was set to -1 and a nonlinear least-square fit using the Levenberg-Marquardt
276 algorithm was performed to generate the final curves.
277
278 Generation of SH2 domain phylogenies
279
280 Phylogenetic trees were generated based on the sequence for each canonical *Homo sapiens* SH2
281 domain. Protein sequences for the SH2 domain regions were mined from NCBI reference sequences,
282 aligned using MUSCLE[24] in SeaView v.5.0.5[25] and were further refined using GBlocks[26] with parameters
283 allowing for the least amount of stringency for retention[27]. Phylogenetic analysis was conducted on the
284 Cyberinfrastructure for Phylogenetic Research (CIPRES) Science Gateway (www.phylo.org[28]) using the
285 RAxML software v.8.2.12[29] with the LG evolutionary and GTRGAMMA models[30]. Branch support was
286 estimated by bootstraps with 700 replications and the constructed phylogram was edited using ITOL
287 (itol.embl.de). SH2 protein nomenclature was determined using UNIPROT (uniprot.org). Accession
288 numbers for individual proteins are available in **Extended Data Table 1**.
289
290 Analysis of primary screening and dose-response data
291
292 Independent replicates for each primary screening and dose-response validation data set are noted in
293 **Extended Data Table 3** and **Extended Data Table 5**, respectively. For each independent target assessed
294 in both primary screening and dose-response formats, an assay signal was calculated from the vehicle
295 control (DMSO) and background from a positive control compound. Passing assay metrics were defined
296 as a signal to background ratio of ≥3 and a Z score of ≥0.3 calculated in Spotfire™ (Tibco). For primary
297 screening experiments, the percent of control (POC) for each replicate per compound was calculated by
298 dividing the assay signal of the test compound by that of the vehicle control. Positive hits were defined
299 as ≤35% POC. For dose-response experiments, K_D values were calculated for each individual replicate
300 curve.
301
302 Mapping of primary screening values onto phylogenetic trees
303
304 Phylogenetic trees were mapped in MS Paint and the resulting X,Y coordinates loaded into
305 Spotfire™(Tibco) along with the tree image described above. Primary screening data was mapped onto
306 the resulting tree template by subtracting the average POC for the test compound from 100 in order to
307 generate dots directly proportional to the strength of each hit. These values were then loaded into

Spotfire™(Tibco) along with the corresponding X,Y coordinates and used to generate a spot layer overlay onto the phylogenetic tree.

Data availability

Images in **Fig.1a** and **Fig.1b** were generated using Biorender.com and in **Fig.1c** and **Fig.1d** using GraphPad Prism. Chemical structures in **Extended Data Fig. 1** were generated using ChemDraw. Construct details, primary screening data and dose-response data for this study are presented in **Extended Data Tables 1-5**. Any other data that support the conclusions of this paper are available upon request.

Extended Data Table 2|Primary screening data for the 9 compounds tested in SH2*scan*. Data is expressed as the mean of the normalized percent of the DMSO vehicle control, ± standard deviation. The number of independent replicates and independent experiments for the shown data are presented in **Extended Data Table 3**. False positives are marked with an asterisk.

Extended Data Table 4|Dissociation constant values for the 9 compounds tested in SH2*scan*. Mean K_D values collected in this study are listed below in nM, ± standard deviation. The number of independent replicates and independent experiments for the shown data are presented in **Extended Data Table 5**. False positives are colored in orange and are denoted with "no hit". False negatives are colored in green. The false positive rate for the study was calculated as 3.8% (35 false positives/918 total tested conditions x 100). The false negative rate for the study was calculated as 0.9% (9 false negatives/918 total tested conditions x 100).

Extended Data Table 5 | Replicate numbers for dissociation constant values for the 9 compounds tested in SH2*scan*. Independent replicate numbers (N) for each dose-response value presented in **Extended Data Table 4** are shown below and were generated from at least one independent experiment. False positives are colored in orange and false negatives are colored in green.

Extended Data Table 6|Literature SH2 domain binding measurements for compounds relevant to this study. Literature values for the SH2 domain binding of compounds tested or related to those tested in this study are shown below in nM. Units reported for these measurements are listed in brackets following the value in the table.
