Prioritizing 2nd order interactions via support vector ranking using sensitivity indices on time series Wnt measurements†

shriprakash sinha*◑

It is widely known that the sensitivity analysis plays a major role in computing the strength of the influence of involved factors in any phenomena under investigation. When applied to expression profiles of various intra/extracellular factors that form an integral part of a signaling pathway, the variance and density based analysis yields a range of sensitivity indices for individual as well as various combinations of factors. These combinations denote the higher order interactions among the involved factors, that might be of interest in the working mechanism of the pathway. For example, there are 19 types of WNTs and 10 FZDs with their 2nd order combinations high enough and it is not possible to know which one to test first (except for those for which wet lab validations have been confirmed). But the effect of these combinations vary over time as measurements of fold changes and deviations in fold changes vary. In this work, after estimating the individual effects of factors for a higher order combination, the individual indices are considered as discriminative features. A combination, then is a multivariate feature set in higher order (>=2). With an excessively large number of factors involved in the pathway, it is difficult to search for important combinations in a wide search space over different orders. Exploiting the analogy of prioritizing webpages using ranking algorithms, for a particular order, a full set of combinations of interactions can then be prioritized based on these features using a powerful ranking algorithm via support vectors. Recording the changing rankings of the combinations over time points and durations, reveals how higher order interactions behave within the pathway and when and where an intervention might be necessary to influence the pathway. This could lead to development of time based therapeutic interventions. Based on a small dataset in time, we were able to generate the rankings of the 2nd order combinations between WNTs and FZDs at different time snap shots and for different duration or time periods. Code has been made available on Google drive at `https://drive.google.com/folderview?id=0B7Kkv8wlhPU-V1Fkd1dMSTd5ak0&usp=sharing`

Significance

The search and wet lab testing of unknown biological hypotheses in the form of combinations of various intra/extracellular factors that are involved in a signaling pathway, costs a lot in terms of time, investment and energy. To reduce this cost of search in a vast combinatorial space, a pipeline has been developed that prioritises these list of combinations so that a biologist can narrow down their investigation. The pipeline uses kernel based sensitivity indices to capture the influence of the factors in a pathway and employs powerful support vector ranking algorithm. The generic workflow and future improvements are bound to cut down the cost for many wet lab experiments and reveal unknown/untested biological hypothesis.

1 Introduction

1.1 A short review

Sharma [1]'s accidental discovery of the Wingless played a pioneering role in the emergence of a widely expanding research field of the Wnt signaling pathway. A majority of the work has focused on issues related to • the discovery of genetic and epigenetic factors affecting the pathway (Thorstensen et al. [2] & Baron and Kneissel [3]), • implications of mutations in the pathway and its dominant role on cancer and other diseases (Clevers [4]), • investigation into the pathway's contribution towards embryo development (Sokol [5]), homeostasis (Pinto et al. [6], Zhong et al. [7]) and apoptosis (Pećina-Šlaus [8]) and • safety and feasibility of drug design for the Wnt pathway (Kahn [9], Garber [10], Voronkov and Krauss [11], Blagodatski et al. [12] & Curtin and Lorenzi [13]). Approximately forty years after the discovery, important strides have been made in the research work involving several wet lab experiments and cancer clinical trials (Kahn [9], Curtin and Lorenzi [13]) which have been augmented by the recent developments in the various advanced computational modeling techniques of the pathway. More recent informative reviews have touched on various issues related to the different types of the Wnt signaling pathway and have stressed not only the activation of the Wnt signaling pathway via the Wnt proteins (Rao and Kühl [14]) but also the on the secretion mechanism that plays a major role in the initiation of the Wnt activity as a prelude (Yu and Virshup [15]).

The work in this paper investigates some of the current aspects of research regarding the pathway via sensitivity analysis while using static (Jiang et al. [16]) and time series (Gujral and MacBeath [17]) gene expression data retrieved from colorectal cancer samples.

1.2 Canonical Wnt signaling pathway

Before delving into the problem statement, a brief introduction to the Wnt pathway is given here. From the recent work of Sinha [18], the canonical Wnt signaling pathway is a transduction mechanism that contributes to embryo development and controls homeostatic self renewal in several tissues (Clevers [4]). Somatic mutations in the pathway are known to be associated with cancer in different parts of the human body. Prominent among them is the colorectal cancer case (Gregorieff and Clevers [19]). In a succinct overview, the Wnt signaling pathway works when the Wnt ligand gets attached to the Frizzled(FZD)/LRP coreceptor complex. FZD may interact with the Dishevelled (DVL) causing phosphorylation. It is also thought that Wnts cause phosphorylation of the LRP via casein kinase 1 ($CK1$) and kinase $GSK3$. These developments further lead to attraction of Axin which causes inhibition of the formation of the degradation complex. The degradation complex constitutes of $AXIN$, the β-catenin transportation complex APC, $CK1$ and $GSK3$. When the pathway is active the disso-

lution of the degradation complex leads to stabilization in the concentration of β-catenin in the cytoplasm. As β-catenin enters into the nucleus it displaces the $GROUCHO$ and binds with transcription cell factor TCF thus instigating transcription of Wnt target genes. $GROUCHO$ acts as lock on TCF and prevents the transcription of target genes which may induce cancer. In cases when the Wnt ligands are not captured by the coreceptor at the cell membrane, $AXIN$ helps in formation of the degradation complex. The degradation complex phosphorylates β-catenin which is then recognized by $FBOX/WD$ repeat protein β-$TRCP$. β-$TRCP$ is a component of ubiquitin ligase complex that helps in ubiquitination of β-catenin thus marking it for degradation via the proteasome. Cartoons depicting the phenomena of Wnt being inactive and active are shown in figures 1(A) and 1(B), respectively.

2 Problem statement & sensitivity analysis

It is widely known that the sensitivity analysis plays a major role in computing the strength of the influence of involved factors in any phenomena under investigation. When applied to expression profiles of various intra/extracellular factors that form an integral part of a signaling pathway, the variance and density based analysis yields a range of sensitivity indices for individual as well as various combinations of factors. These combinations denote the higher order interactions among the involved factors. Computa-

tion of higher order interactions is often time consuming but they give a chance to explore the various combinations that might be of interest in the working mechanism of the pathway. For example, in a range of fourth order combinations among the various factors of the Wnt pathway, it would be easy to assess the influence of the destruction complex formed by APC, AXIN, CSKI and GSK3 interaction. But the effect of these combinations vary over time as measurements of fold changes and deviations in fold changes vary. So it is imperative to know how an interaction or a combination of the involved factors behave in time and a procedure needs to be developed that can track the behaviour by exploiting the influences of the involved factors.
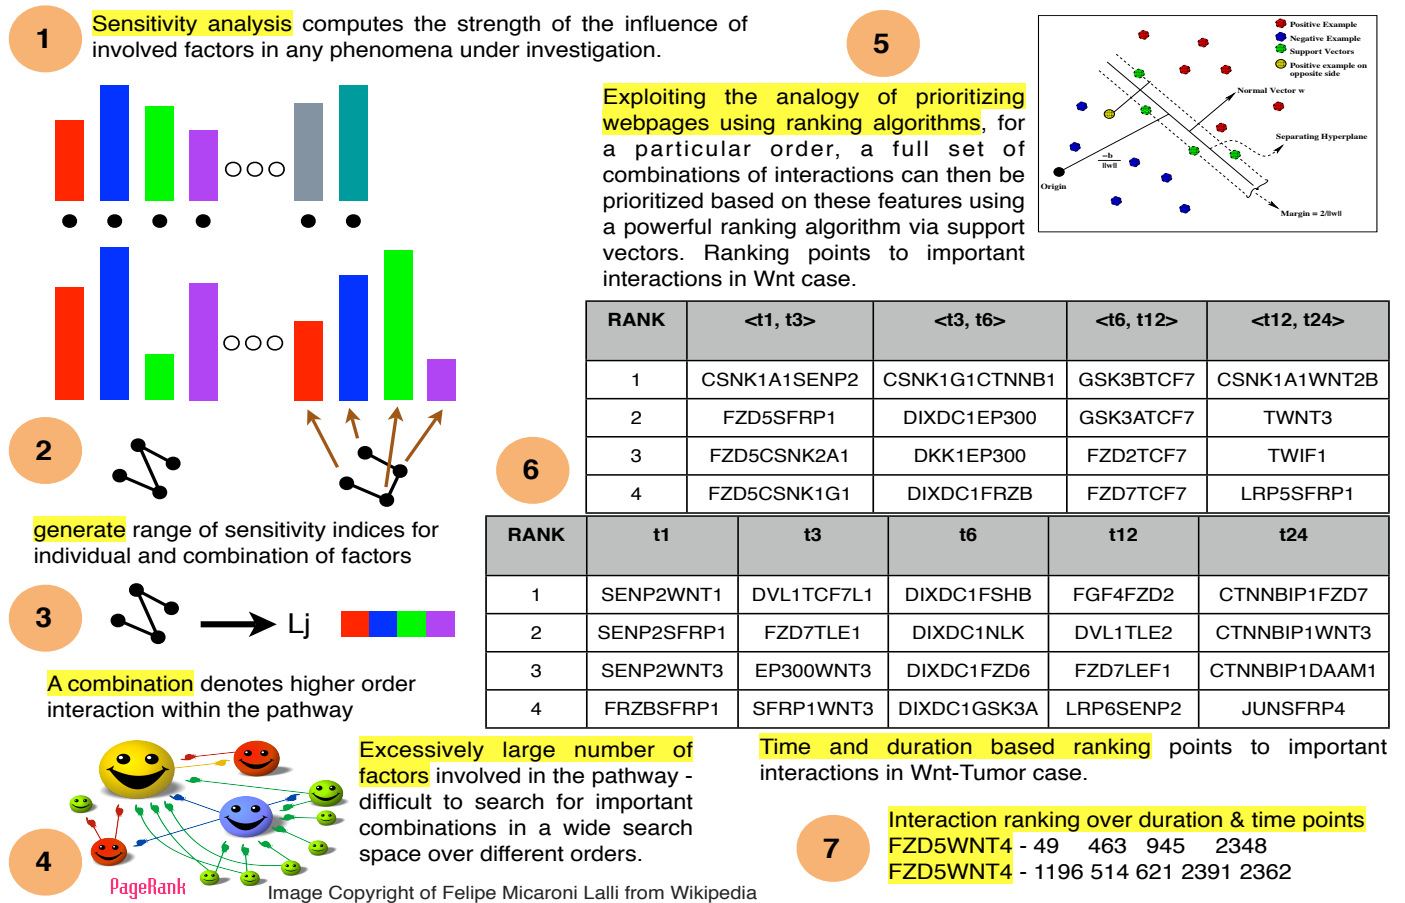

In this work, after estimating the individual effects of factors for a higher order combination, the individual indices are considered as discriminative features. A combination, then is a multivariate feature set in higher order (>2). With an excessively large number of factors involved in the pathway, it is difficult to search for important combinations in a wide search space over different orders. Exploiting the analogy with the issues of prioritizing webpages using ranking algorithms, for a particular order, a full set of combinations of interactions can then be prioritized based on these features using a powerful ranking algorithm via support vectors (Joachims[20]). Recording the changing rankings of the combinations over time reveals of how higher order interactions behave within the pathway and when an intervention might be necessary to influence the interaction within the pathway. This could lead to development of time based therapeutic interventions. A graphical abstract of how the search engine works to find the crucial interactions by ranking in time has been represented in figure 2.

2.1 Sensitivity analysis

Seminal work by Russian mathematician Sobol'[21] lead to development as well as employment of SA methods to study various complex systems where it was tough to measure the contribution of various input parameters in the behaviour of the output. A recent unpublished review on the global SA methods by Iooss and Lemaître[22] categorically delineates these methods with the following functionality • screening for sorting influential measures (Morris[23] method, Group screening in Moon et al.[24] & Dean and Lewis[25], Iterated factorial design in Andres and Hajas[26], Sequential bifurcation in Bettonvil and Kleijnen[27] and Cotter[28] design), • quantitative indicies for measuring the importance of contributing input factors in linear models (Christensen[29], Saltelli et al.[30], Helton and Davis[31] and McKay et al.[32]) and nonlinear models (Homma and Saltelli[33], Sobol[34], Saltelli[35], Saltelli et al.[36], Saltelli et al.[37], Cukier et al.[38], Saltelli et al.[39], & Tarantola et al.[40] Saltelli et al.[41], Janon et al.[42], Owen[43], Tissot and Prieur[44], Da Veiga and Gamboa[45], Archer et al.[46], Tarantola

et al.[47], Saltelli and Annoni[48] and Jansen[49]) and • exploring the model behaviour over a range on input values (Storlie and Helton[50] and Da Veiga et al.[51], Li et al.[52] and Hajikolaei and Wang[53]). Iooss and Lemaître[22] also provide various criteria in a flowchart for adapting a method or a combination of the methods for sensitivity analysis. Figure 3 shows the general flow of the mathematical formulation for computing the indices in the variance based Sobol method. The general idea is as follows - A model could be represented as a mathematical function with a multidimensional input vector where each element of a vector is an input factor. This function needs to be defined in a unit dimensional cube. Based on ANOVA decomposition, the function can then be broken down into f_0 and summands of different dimensions, if f_0 is a constant and integral of summands with respect to their own variables is 0. This implies that orthogonality follows in between two functions of different dimensions, if at least one of the variables is not repeated. By applying these properties, it is possible to show that the function can be written into a unique expansion. Next, assuming that the function is square integrable variances can be computed. The ratio of variance of a group of input factors to the variance of the total set of input factors constitute the sensitivity index of a particular group. Detailed derivation is present in the Appendix.

Besides the above Sobol'[21]'s variance based indicies, more recent developments regarding new indicies based on density, derivative and goal-oriented can be found in Borgonovo[54], Sobol and Kucherenko[55] and Fort et al.[56], respectively. In a latest development, Da Veiga[57] propose new class of indicies based on density ratio estimation (Borgonovo[54]) that are special cases of dependence measures. This in turn helps in exploiting measures like distance correlation (Székely et al.[58]) and Hilbert-Schmidt independence criterion (Gretton et al.[59]) as new sensitivity indicies. The framework of these indicies is based on use of Csiszár et al.[60] f-divergence, concept of dissimilarity measure and kernel trick Aizerman et al.[61]. Finally, Da Veiga[57] propose feature selection as an alternative to screening methods in sensitivity analysis. The main issue with variance based indicies (Sobol'[21]) is that even though they capture importance information regarding the contribution of the input factors, they • do not handle multivariate random variables easily and • are only invariant under linear transformations. In comparison to these variance methods, the newly proposed indicies based on density estimations (Borgonovo[54]) and dependence measures are more robust. Figure 4 shows the general flow of the mathematical formulation for computing the indices in the density based HSIC method. The general idea is as follows - The sensitivity index is actually a distance correlation which incorporates the kernel based Hilbert-Schmidt Information Criterion between two input vectors in higher dimension. The criterion is nothing but the Hilbert-Schmidt norm of cross-covariance operator which generalizes the covariance ma-

trix by representing higher order correlations between the input vectors through nonlinear kernels. For every operator and provided the sum converges, the Hilbert-Schmidt norm is the dot product of the orthonormal bases. For a finite dimensional input vectors, the Hilbert-Schmidt Information Criterion estimator is a trace of product of two kernel matrices (or the Gram matrices) with a centering matrix such that HSIC evalutes to a summation of different kernel values. Detailed derivation is present in the Appendix.

It is this strength of the kernel methods that HSIC is able to capture the deep nonlinearities in the biological data and provide reasonable information regarding the degree of influence of the involved factors within the pathway. Improvements in variance based methods also provide ways to cope with these nonlinearities but do not exploit the available strength of kernel methods. Results in the later sections provide experimental evidence for the same.

2.2 Relevance in systems biology

Recent efforts in systems biology to understand the importance of various factors apropos output behaviour has gained prominence. Sumner *et al.*[62] compares the use of Sobol'[21] variance based indices versus Morris[23] screening method which uses a One-at-a-time (OAT) approach to analyse the sensitivity of $GSK3$ dynamics to uncertainty in an insulin signaling model. Similar efforts, but on different pathways can be found in Zheng and Rundell[63] and Marino *et al.*[64].

SA provides a way of analyzing various factors taking part in a biological phenomena and deals with the effects of these factors on the output of the biological system under consideration. Usually, the model equations are differential in nature with a set of inputs and the associated set of parameters that guide the output. SA helps in observing how the variance in these parameters and inputs leads to changes in the output behaviour. The goal of this manuscript is not to analyse differential equations and the parameters associated with it. Rather, the aim is to observe which input
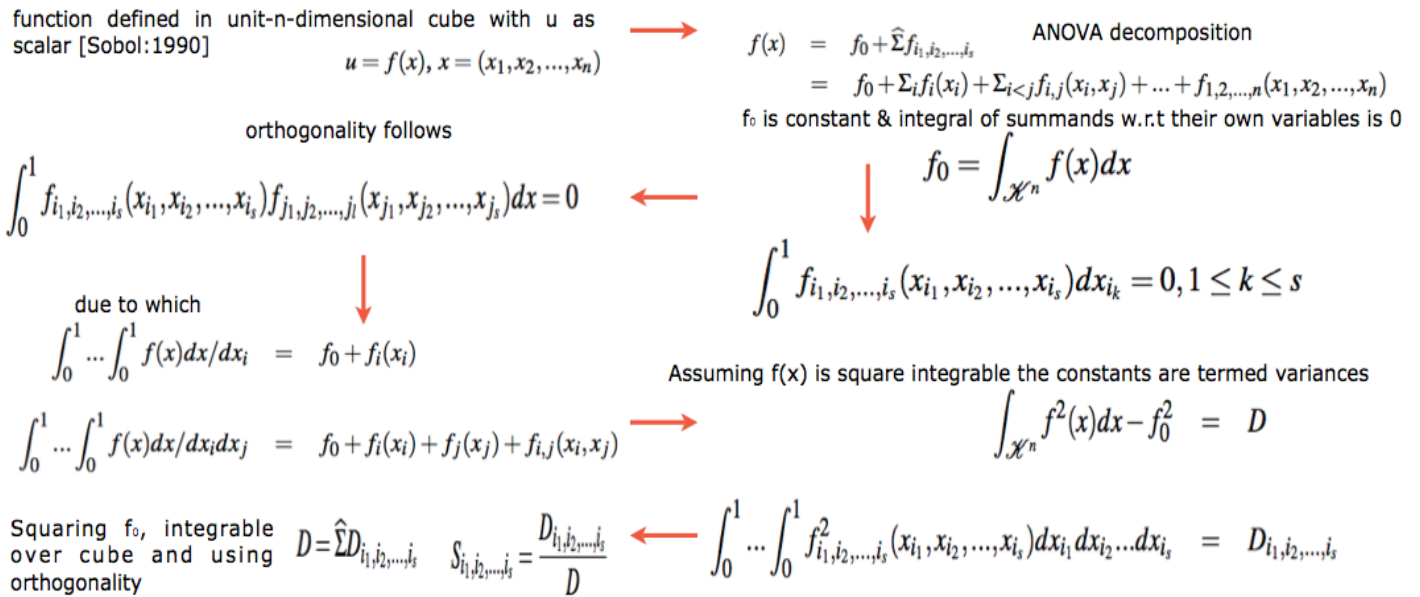

Fig. 3 Computation of variance based sobol sensitivity indices. For detailed notations, see appendix.

genotypic factors have greater contribution to observed phenotypic behaviour like a sample being normal or cancerous in both static and time series data. In this process, the effect of fold changes and deviations in fold changes in time is also considered for analysis in the light of the recently observed psychophysical laws acting downstream of the Wnt pathway (Goentoro and Kirschner[65]).

There are two approaches to sensitivity analysis. The first is the local sensitivity analysis in which if there is a required solution, then the sensitivity of a function apropos a set of variables is estimated via a partial derivative for a fixed point in the input space. In global sensitivity, the input solution is not specified. This implies that the model function lies inside a cube and the sensitivity indices are regarded as tools for studying the model instead of the solution. The general form of g-function (as the model or output variable) is used to test the sensitivity of each of the input factor (i.e expression profile of each of the genes). This is mainly due to its non-linearity, non-monotonicity as well as the capacity to produce analytical sensitivity indices. The g-function takes the form -

$$f(x) = \Pi_{i=1}^{d} \frac{|4 * x_i - 2| + a_i}{1 + a_i} \tag{1}$$

were, d is the total number of dimensions and $a_i \geq 0$ are the indicators of importance of the input variable x_i. Note that lower values of a_i indicate higher importance of x_i. In our formulation, we randomly assign values of $x_i \in [0,1]$. For the static (time series) data $d = 71$ (factors affecting the pathway). The value of d varies from 2 to 70, depending on the order of the combina-

tion one might be interested in. Thus the expression profiles of the various genetic factors in the pathway are considered as input factors and the global analysis conducted. Note that in the predefined dataset, the working of the signaling pathway is governed by a preselected set of genes that affect the pathway. For comparison purpose, the local sensitivity analysis method is also used to study how the individual factor is behaving with respect to the remaining factors while working of the pathway is observed in terms of expression profiles of the various factors.

Finally, in context of Goentoro and Kirschner[65]'s work regarding the recent development of observation of Weber's law working downstream of the pathway, it has been found that the law is governed by the ratio of the deviation in the input and the absolute input value. More importantly, it is these deviations in input that are of significance in studing such a phemomena. The current manuscript explores the sensitivity of deviation in the fold changes between measurements of fold changes at consecutive time points to explore in what duration of time, a particular factor is affecting the pathway in a major way. This has deeper implications in the fact that one is now able to observe when in time an intervention can be made or a gene be perturbed to study the behaviour of the pathway in tumorous cases. Thus sensitivity analysis of deviations in the mathematical formulation of the psychophysical law can lead to insights into the time period based influence of the involved factors in the pathway. Thus, both global and local anaylsis methods are employed to observe the entire behaviour of the pathway as well as the local behaviour of the input factors with respect to the other factors, respectively, via analysis

Fig. 4 Computation of density based hsic sensitivity indices. For detailed notations, see appendix.

of fold changes and deviations in fold changes, in time.

Given the range of estimators available for testing the sensitivity, it might be useful to list a few which are going to be employed in this research study. Also, a brief introduction into the fundamentals of the derivation of the three main indicies and the choice of sensitivity packages which are already available in literature, has been described in the Appendix.

2.3 Ranking Support Vector Machines

Learning to rank is a machine learning approach with the idea that the model is trained to learn how to rank. A good introduction to this work can be found in[66]. Existing methods involve pointwise, pairwise and listwise approaches. In all these approaches, Support Vector Machines (SVM) can be employed to rank the required query. SVMs for pointwise approach build various hyperplanes to segregate the data and rank them. Pairwise approach uses ordered pair of objects to classify the objects and then utilize the classifyer to rank the objects. In this approach, the group structure of the ranking is not taken into account. Finally, the listwise ranking approach uses ranking list as instances for learning and prediction. In this case the ranking is straightforward and the group structure of ranking is maintained. Various different designs of SVMs have been developed and the research in this field is still in preliminary stages. In context of the gene expression data set employed in this manuscript, the objects are the genes with their recorded FOLD CHANGE EXPRESSION VALUES AT DIFFERENT TIME SNAP SHOTS. Another case is the genes with

their recorded DEVIATIONS IN FOLD CHANGE EXPRESSION VALUES IN BETWEEN TIME SNAP SHOTS.

Note that rankings algorithms have been developed to be employed in the genomic datasets but to the author's awareness, these algorithms do not rank the range of combinations in a wide combinatorial search space in time. Also, they do not take into account the ranking of unexplored biological hypothesis which are assigned to a particular sensitivity value or vector that can be used for prioritization. For example, Kolde et al.[67] presents a ranking algorithm that betters existing ranking model based on the assignment of P-value. As stated by Kolde et al.[67] it detects genes that are ranked consistently better than expected under null hypothesis of uncorrelated inputs and assigns a significance score for each gene. The underlying probabilistic model makes the algorithm parameter free and robust to outliers, noise and errors. Significance scores also provide a rigorous way to keep only the statistically relevant genes in the final list. The proposed work here develops on sensitivity analysis and computes the influences of the factors for a system under investigation. These sensitivity indices give a much realistic view of the biological influence than the proposed P-value assignment and the probabilistic model. The manuscript at the current stage does not compare the algorithms as it is a pipeline to investigate and conduct a systems wide study. Instead of using SVM-Ranking it is possible to use other algorithms also, but the author has restricted to the development of the pipeline per se. Finally, the current work tests the effectiveness of the variance based (SOBOL) sensitivity indices apropos the density and kernel based (HSIC) sensitivity

indices. Finally, Blondel *et al.*[68] provides a range of comparison for 10 different regression methods and a score to measure the models. Compared to the frame provided in Blondel *et al.*[68], the current pipeline takes into account biological information an converts into sensitivity scores and uses them as discriminative features to provide rankings. Thus the proposed method is algorithm independent.

3 Description of the dataset & design of experiments

Gujral and MacBeath[17] present a bigger set of 71 Wnt-related gene expression values for 6 different times points over a range of 24-hour period using qPCR. The changes represent the fold-change in the expression levels of genes in 200 ng/mL $WNT3A$-stimulated HEK 293 cells in time relative to their levels in unstimulated, serum-starved cells at 0-hour. The data are the means of three biological replicates. Only genes whose mean transcript levels changed by more than two-fold at one or more time points were considered significant. Positive (negative) numbers represent up (down) -regulation. Note that green (red) represents activation (repression) in the heat maps of data in Gujral and MacBeath[17]. For the case of time series data, interactions among the contributing factors are studied by comparing (1) pairs of fold-changes at single time points and (2) pairs of deviations in fold changes between pairs of time points.

The prodecure begins with the generation of distribution around measurements at single time points with added noise is done to estimate the indices. Two types of distributions are generated; One for the fold changes at single time points and the other for deviations in fold changes that recorded between fold changes at two time points. Then for every gene, there is a vector of values representing fold changes as well as deviations in fold changes for different time points and durations between time points, respectively. Next a listing of all C_k^n combinations for k number of genes from a total of n genes is generated. k is ≥ 2 and $\leq (n-1)$. Each of the combination of order k represents a unique set of interaction between the involved genetic factors. After this, the datasets are combined in a specifed format which go as input as per the requirement of a particular sensitivity analysis method. Thus for each pth combination in C_k^n combinations, the dataset is prepared in the required format from the distributions for two separate cases which have been discussed above. (See .R code in mainScript-1-1.R in google drive and step 4 in figure 5). After the data has been transformed, vectorized programming is employed for density based sensitivity analysis and looping is employed for variance based sensitivity analysis to compute the required sensitivity indices for each of the p combinations. This procedure is done for different kinds of sensitivity analysis methods.

After the above sensitivity indices have been stored for each of the pth combination, the next step in the design of experiment is conducted. Since there is only one recording of sensitivity index per combination, each combination forms a training example which is alloted a training index and the sensitivity indices of the individual genetic factors form the training example. Thus there are C_k^n training examples for k^{th} order interaction. Using this training set SVM_{learn}^{Rank} (Joachims[20]) is used to generate a model on default value C value of 20. In the current experiment on toy model C value has not been tunned. The training set helps in the generation of the model as the different gene combinations are numbered in order which are used as rank indices. The model is then used to generate score on the observations in the testing set using the $SVM_{classify}^{Rank}$ (Joachims[20]). Note that due to availability of only one example per combination, after the model has been built, the same training data is used as test data to generates the scores. This procedure is executed for each and every sensitivity analysis method. This is followed by sorting of these scores along with the rank indices (i.e the training indices) already assigned to the gene combinations. The end result is a sorted order of the gene combinations based on the ranking score learned by the SVM^{Rank} algorithm. Finally, this entire procedure is computed for sensitivity indices generated for each and every fold change at time point and deviations in fold change at different durations. Observing the changing rank of a particular combination at different times and different time periods will reveal how a combination is behaving. These steps are depicted in figure 6.

Note that the following is the order in which the files should be executed in R, in order, for obtaining the desired results (Note that the code will not be explained here) - • use source("mainScript-1-1.R") with arguments for Dynamic data • source("SVMRank-Results-D.R"), to rank the interactions (again this needs to be done separately for different kinds of SA methods), • use source("Combine-Time-files.R"), if computing indices separately via previous file, • source("Sort-n-Plot-D.R") to sort the interactions. Note that the sorting is chages the interaction ranking in time. Thus • use source("Interaction-Priority-Intime.R") to find the prioritized ranking of each and every interaction over the different time points and finally • use source("Print-Ranking-AND-Interaction-Rank.R") to print individual ranking of the required input factor with other interaction factors.

4 Results and Discussion

Results for the 2nd order interactions are presented here. The results first discuss the behaviour of interactions across the snapshots of time using the computed sensitivities on fold change measurements per time snapshot. Next the behaviour of the interactions during the time intervals is analysed based on the computed sensitivities on deviations on fold change measurements per time
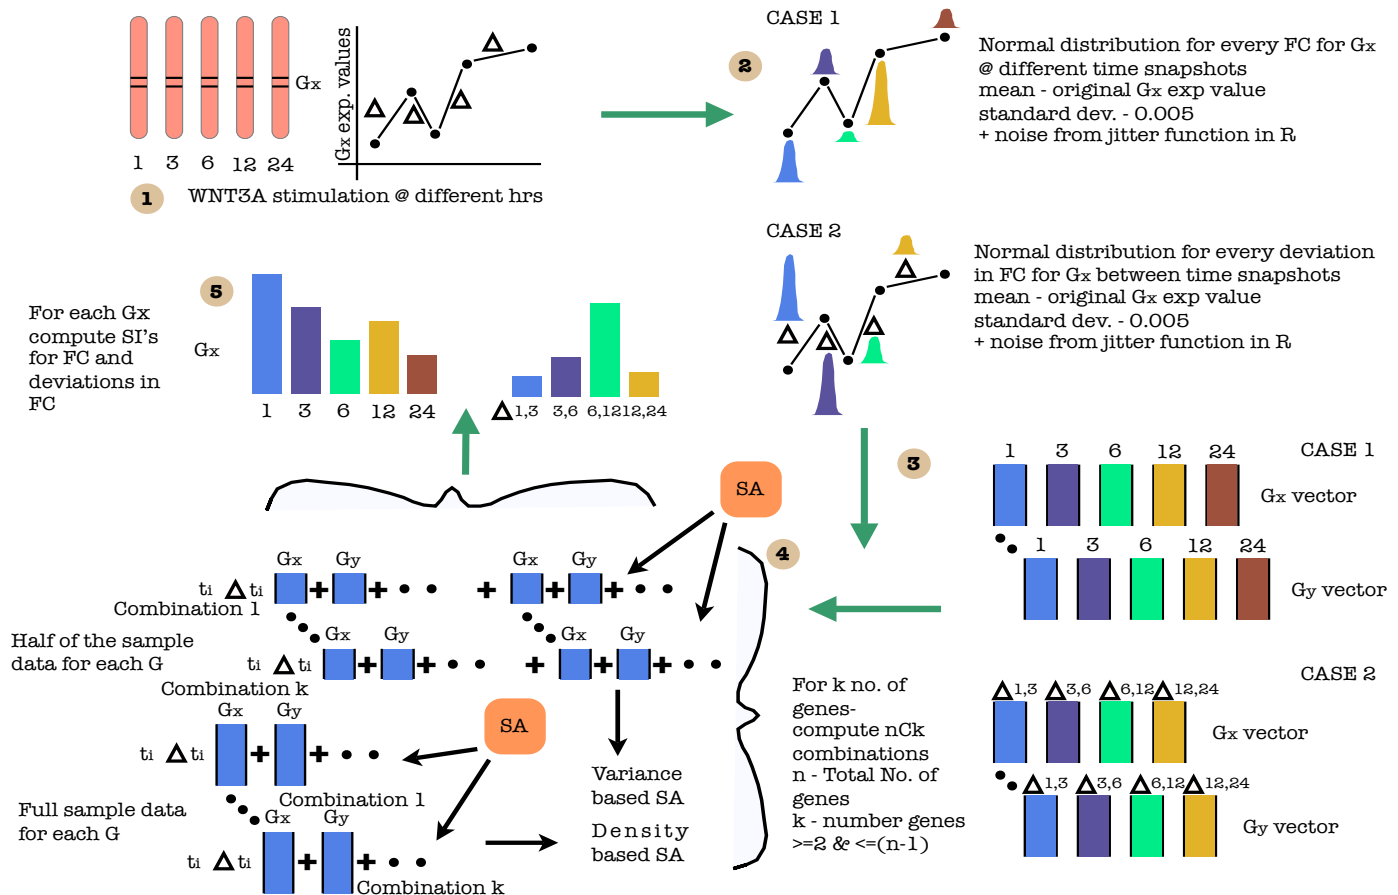

Fig. 5 A cartoon of experimental setup. Step - (1) Time recordings of different gene expression values after WNT3A stimulation at different hrs. Generate deviations in fold changes per gene using the fold change recordings pers time point. (2) Generate of normal distribution for every FC & ΔFC for Gx at & between different time snapshots, respectively. mean - original Gx exp value; standard dev. - 0.005 + noise from jitter function in R (3) Generation of data set for FC & ΔFC. (4) For k number of genes, compute C_k^n combinations and for every SA method, combine data in a specified format for both FC & ΔFC. (5) Compute SI for FC & ΔFC for different.

interval. The analysis was done on 12 different sensitivity indices. Results obtained for one of the indices is explained. Next, individual rankings of a few interactions are discussed with respect to the used indices. Finally, the similar rankings for different sensitivity analysis method are made available at the website with contains the code for the same.

4.1 2nd order interaction rankings at t_i snapshot & $\Delta t_{i,i+1}$ interval

Table 1 (2) shows the 1st first 15 and the last 15 ranking of the interactions in the first and the third slot of the 15 rows each, for time snapshots (for time periods between the snapshots). The next two slots contain the ranking behaviour of 1st 15 & last 15 interactions at different time snapshots (different time periods for table 2). Note that the interaction order for this second slot

of rows is based on the ranking obtained at t_1 ($\Delta t_{1,3}$) in table 1 (2). First, the ranking for each of the interaction was generated per time snap shot. Column wise, it is observed that any interaction will take up different ranks at the different time snapshots (and time periods). This ranking is based on the sensitivity indices that capture the amount of influence that the combination of factors have on the signaling pathway. To have a better view of how the individual interaction works, the rankings of a particular interaction across the different time snapshots (and time periods) were extracted from the entire set of rankings of all interactions per time snapshot (ans time periods). Both tables 1 and 2 show a glimpse of a few 2nd order interactions out of the total of 71 genes. The total number of combinations are $C_2^{71} = \frac{71!}{2! \times 69!} = 2485$.

What we find is that the interactions or combinations are
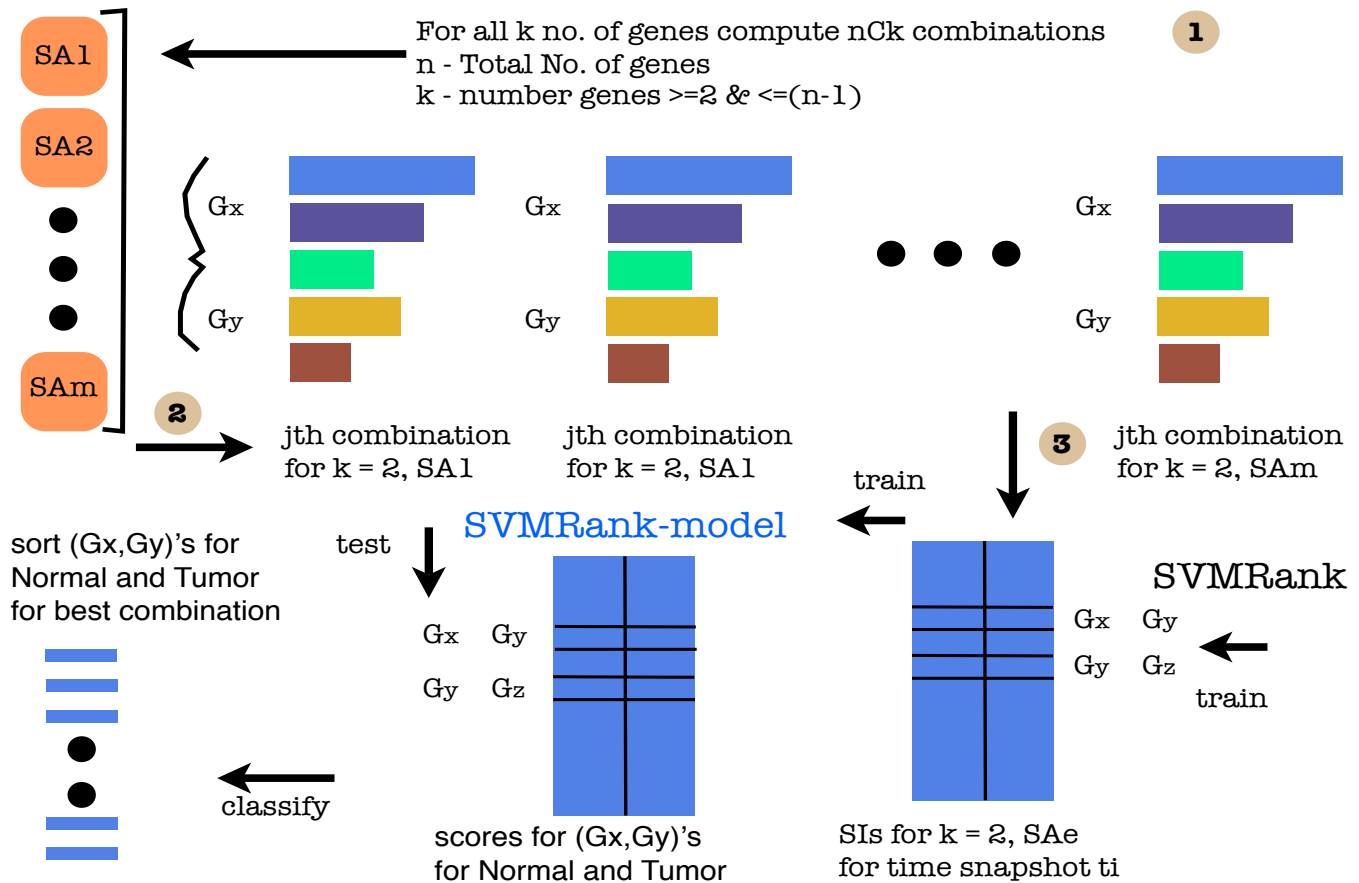

Fig. 6 A cartoon of experimental setup. Step - (1) For k^{th} order genes in C_k^n combinations and for every SA, combine (say for $k = 2$, i.e interaction level 2) SI's of genetic factors form training data. (3) Using indices in (1) SVM_{learn}^{Rank} is employed on training data to generate a model. This model is used to generate a ranking score on the training data again via $SVM_{classify}^{Rank}$. Finally the combinations are ranked based on sorting of training set. This is generated for each and every FC as well as ΔFC. Observing changing ranking in time & time periods reveals how a particular combination is behaving.

ranked but they do-not explicitly state the direct or indirect dependencies between the combinations. For example, we find that *FZD7-LEF1* have an extremely high ranking of 3 at time snapshot t_{12} in table 1. There might not be a direct link between these two but the prioritised list indicates their high ranking in the Wnt pathway at a certain stage and affecting these two in wet lab experiment at this stage would reveal a possible insights into the connectivity or influence these two have on the pathway. Thus unexplored biological hypothesis could be tested using these rankings. If we look at the *SENP2-WNT1* combination and its ranking over time snapshots in table 1, we find that its influence on the pathway is extremely high except at time points t_3 and t_{24}. This suggests that the combination of *SENP2-WNT1* might be playing an a highly influencing role in the pathway, either directly or indirectly. Recently, it has been shown by Du *et al.* [69],

that *SENP2*, a member of the family SUMOylation-related proteins does have increased level of expression in colorectal cancer cell lines. Thus, studying the ranking of a combination at various time snap shots can facilitate in understanding the influence of the combination as well as testing the unexplored biological hypothesis and developing target based therapeutic drugs that can interven the pathway.

In table 2, we observe similar rankings but instead of considering the prioritization at time points, we consider ranking at time periods. These are of much more greater importance that the rankings at the time points. This is attributed to the fact that the deviation in fold changes in between the recorded fold changes at consecutive time points indicate how much a particular combination is influencing the pathway in that particular period of time. Currently, the proposed insilico pipeline takes into account

the data that has been recorded at long intervals of time (see Gujral and MacBeath [17]). But recordings at shorter time intervals will give a more detailed ranking list for the different time periods. *FZD7-LRP6* combination shows an extremely high ranking

in the first period of $t_{1,3}$. But its ranking goes down in the second period before it steadily rises in ranking in the later periods. This suggests that in the initial period the combination of $FZD7$-$LRP6$ is extremely crucial when the $WNT3A$ is been injected into the cell and the signaling has gained momentum. During the next period, the ranking significantly drops to a very low value indicating that the combination at the receptor level is not that effective. But this reverses in the next two periods. These changing rankings over time periods shows in which time period, a combination might be effective in the pathway and help the biologists to intervene the pathway at that particular period of time.

Gujral and MacBeath[17] proposes a system wide analysis of the WNT pathway in which the analysis of $CTBP1$-MYC has been presented. It was observed that $CTBP1$ plays a positive role in the WNT pathway as a transcription factor in the early phases of the pathway and is correlated with the time dependent profile of MYC. The current pipeline confirms the wet lab experiments by indicating the changing ranking in time. For rankings in time-points •$CTBP2MYC$ 401 352 433 1765 2024 •$CTBP1MYC$ 411 2011 580 683 1227, it was found that $CTBP1$ and MYC have similar affect on the pathway. Initially the ranking is high but goes down significantly at the second timesnap shot before showing a decreasing peaked behaviour. Similarly, $CTBP2$ (though not reported in Gujral and MacBeath[17]) shows that a similar ranking pattern as the $CTBP1$-MYC. These findings point to the efficacy of the proposed pipeline. A further analysis of rankings in time periods show a completely different profile - •$CTBP2MYC$ 1848 941 2037 1692 •$CTBP1MYC$ 980 2321 2387 1558. These rankings over time periods give a different picture mainly due to the large gaps in time snapshot recordings. As stated earlier, the significance might be much improved if the duration between the time points at which the $WNT3A$ is being injected is shortened. In general, a system wide analysis is now possible with a pipeline as developed in this work, which prioritises the interactions or combinations in a pathway over time snapshots and period of time.

4.2 Analysis of WNT-FZD variants at t_i snapshot & $\Delta t_{i,i+1}$ interval

It is widely known that the family of WNT and FZD interact at the cell surface to instigate the pathway. Hsieh et al.[70] conducted one of the earliest biochemical characterisation of the WNT-FZD interactions. The most recent wet lab study to map the particular combinations of WNT-FZD was done by Dijksterhuis et al.[71]. Albeit the different cell lines used for finding the combinations of WNT-FZD, we would like to know if the combinations generated by the proposed pipeline in this work have some match with the existing wet lab tested combinations. The existing problem with the combinations of WNT-FZD is that there is a large

range of combinations of the order of C_2^{29} and the mapping of these combinations have not been done extensively. The reasons for this are purely biological in nature as unknown specific WNT binding activities and lack of binding assays for full length receptors (Dijksterhuis et al.[71]). Nevertheless, despite these hinderances, advances in wet lab have been made to map these combinations. The major problem here is the amount to time needed to search for these specific bindings and from a biological standpoint, it is not easy to find which combination to search for first, given the vast combinatorial space. We test the pipeline to generate ranks for a few WNT-FZD interactions and a prioritised list has been provided which contains the changing ranks at different time points and time periods. For data set generated from the cell lines in Gujral and MacBeath[17], a limited number of WNT and FZD family members were profiled as the $WNT3A$ molecule was injected into the serum starved cells. Tables 3 and 4 represent the rankings at different time points while tables 5 and 6 represent the rankings at different time periods, for the different WNT-FZD interactions.

Table 5 2nd order interaction ranking for FZD-WNT variants using HSIC-rbf for different intervals of time. Total number of interactions were C_2^{71}.

Dijksterhuis *et al.*[71] conclude in their wet lab findings that $WNT-3A/4/5A$ functionally bind to $FZD-2/4/5$. Of the recorded rankings of $FZD2$ with the above $WNTs$, the combination of $FZD2$-$WNT-4/5A$ showed a moderately high rank of around 600 in C_2^{71} combinations, at time point t_6. Additionally, the pipeline also generated higher ranking for interactions $FZD2$-$WNT-2/2B/3$ at other time points in the later stage of the pathway (table 4). $FZD5$ also showed confirmatory results with $WNT-3A/4/5$ (tables and 3 4). Rankings of these interactions are relatively moderate/weak but show promise in the fact that molecules do bind during the signaling process. Apart from these interactions, other recorded rankings for $FZD5$ that showed high affinity for variants of WNTs were $FZD5$-$WNT-1/2B/3$ (the higer ranks in the aforementioned tables). $FZD5$-$WNT2$ did not show that high ranking in comparison to their other counterparts. Similarly, $FZD7$ showed high binding affinity to $WNT-1/2/2B/3/5A/$ at different time points and lower or weaker affinity for $WNT-3A/4$. $FZD8$ showed high binding affinity to $WNT-1/2B/3/5A$ at different time points and lower or weaker affinity for $WNT-2/3A/4$. $FZD1$ showed high binding affinity to $WNT-1/2/2B/3/3A/4/5A$ at differ-

ent time points. Finally, $FZD6$ showed strong affinity at singular time points with $WNT-1/2/2B/3/3A/5A$ and overall relatively moderate or weak affinity to $WNT-3A/4/5A$. Similar confirmatory results of binding have been found in wet lab tests in Ueno *et al.*[72] and Vincan *et al.*[73]. Finally, similar interpretations can be made for the FZD-WNT interactions for the different durations or time periods as has been shown in tables 5 and 6.

The appendix contains a list of rankings for 2nd order combinations for different factors at different time points and time durations. These contain the unexplored biological hypotheses for Wnt signaling pathway.

5 Conclusion

COMPUTATIONAL - A pipeline has been developed to prioritise an nth order combination of factors that affect a signaling pathway. It takes into account the sensitivity indices computed from variance based (SOBOL) and density-kernel based (HSIC) methods to estimate the influence of each factor or combination of fac-

RANKING @ $\Delta t_{i,i+1}$ FOR FZD-WNT INTERACTION

2nd order intr.	$\Delta t_{1,3}$	$t_{3,6}$	$t_{6,12}$	$t_{12,24}$
FZD8WNT1	2094	42	260	493

tors. These are then fed as feature vectors into a powerful support vector ranking algorithm that produces a ranked list of the interactions/combinations. The pipeline is aimed to (1) reveal important combinations that form unexplored biological hypotheses (2) study the behaviour of these combinations in time (3) reduce the cost in time/energy for the biologists by providing a prioritized list in a vast combinatorial search space (4) reveal target sites for therapeutic interventions and (5) facilitate in conducting system wide analysis via observation of changing rankings in time.

BIOLOGICAL - The pipeline provides a prioritised list of important 2nd order combinations of a range of family of genes involved in the Wnt pathway. More specifically, it reveals the various unexplored *FZD-WNT* combinations that have been untested till now in the pathway. Due to paucity of space, an extensive prioritised list has been provided in the appendix for wet lab testing.

Appendix

6.1 Sensitivity indices

Given the range of estimators available for testing the sensitivity, it might be useful to list a few which are going to be employed in this research study. Also, a brief introduction into the fundamentals of the derivation of the three main indicies has been provided.

6.1.1 Variance based indices

The variance based indices as proposed by Sobol'[21] prove a theorem that an integrable function can be decomposed into summands of different dimensions. Also, a Monte Carlo algorithm is used to estimate the sensitivity of a function apropos arbitrary group of variables. It is assumed that a model denoted by function $u = f(x)$, $x = (x_1, x_2, ..., x_n)$, is defined in a unit n-dimensional cube $\mathcal{K}^n$ with u as the scalar output. The requirement of the problem is to find the sensitivity of function $f(x)$ with respect to different variables. If $u^* = f(x^*)$ is the required solution, then the sensitivity of u^* apropos x_k is estimated via the partial derivative $(\partial u / \partial x_k)_{x=x^*}$. This approach is the local sensitivity. In global sensitivity, the input $x = x^*$ is not specified. This implies that the model $f(x)$ lies inside the cube and the sensitivity indices are regarded as tools for studying the model instead of the solution. Detailed technical aspects with examples can be found in Homma and Saltelli[33] and Sobol[74].

Let a group of indices $i_1, i_2, ..., i_s$ exist, where $1 \le i_1 < ... < i_s \le n$ and $1 \le s \le n$. Then the notation for sum over all different groups of indices is -

$$\widehat{\Sigma} T_{i_1,i_2,...,i_s} = \Sigma_{i=1}^n T_i + \Sigma_{s=1}^n \Sigma_{1 \le i < j \le n} T_{i,j} + ... + T_{1,2,...,n} \quad (2)$$

Then the representation of $f(x)$ using equation 2 in the form -

$$f(x) = f_0 + \widehat{\Sigma} f_{i_1,i_2,...,i_s}$$
$$= f_0 + \Sigma_i f_i(x_i) + \Sigma_{i<j} f_{i,j}(x_i, x_j) + ... + f_{1,2,...,n}(x_1, x_2, ..., x_n) \quad (3)$$

is called ANOVA-decomposition from Archer *et al.*[46] or expansion into summands of different dimensions, if f_0 is a constant and integrals of the summands $f_{i_1,i_2,...,i_s}$ with respect to their own variables are zero, i.e,

$$f_0 = \int_{\mathcal{K}^n} f(x) dx \quad (4)$$

$$\int_0^1 f_{i_1,i_2,...,i_s}(x_{i_1}, x_{i_2}, ..., x_{i_s}) dx_{i_k} = 0, 1 \le k \le s \quad (5)$$

It follows from equation 4 that all summands on the right hand side are orthogonal, i.e if at least one of the indices in $i_1, i_2, ..., i_s$

and $j_1, j_2, ..., j_l$ is not repeated i.e

$$\int_0^1 f_{i_1,i_2,...,i_s}(x_{i_1}, x_{i_2}, ..., x_{i_s}) f_{j_1,j_2,...,j_l}(x_{j_1}, x_{j_2}, ..., x_{j_s}) dx = 0 \quad (6)$$

Sobol'[21] proves a theorem stating that there is an existence of a unique expansion of equation 4 for any $f(x)$ integrable in $\mathcal{K}^n$. In brief, this implies that for each of the indices as well as a group of indices, integrating equation 4 yields the following -

$$\int_0^1 ... \int_0^1 f(x) dx/dx_i = f_0 + f_i(x_i) \quad (7)$$

$$\int_0^1 ... \int_0^1 f(x) dx/dx_i dx_j = f_0 + f_i(x_i) + f_j(x_j) + f_{i,j}(x_i, x_j) \quad (8)$$

were, dx/dx_i is $\prod_{\forall k \in \{1,..,n\}; i \notin k} dx_k$ and $dx/dx_i dx_j$ is $\prod_{\forall k \in \{1,..,n\}; i,j \notin k} dx_k$. For higher orders of grouped indices, similar computations follow. The computation of any summand $f_{i_1,i_2,...,i_s}(x_{i_1}, x_{i_2}, ..., x_{i_s})$ is reduced to an integral in the cube $\mathcal{K}^n$. The last summand $f_{1,2,...,n}(x_1, x_2, ..., x_n)$ is $f(x) - f_0$ from equation 4. Homma and Saltelli[33] stresses that use of Sobol sensitivity indices does not require evaluation of any $f_{i_1,i_2,...,i_s}(x_{i_1}, x_{i_2}, ..., x_{i_s})$ nor the knowledge of the form of $f(x)$ which might well be represented by a computational model i.e a function whose value is only obtained as the output of a computer program.

Finally, assuming that $f(x)$ is square integrable, i.e $f(x) \in \mathcal{L}_2$, then all of $f_{i_1,i_2,...,i_s}(x_{i_1}, x_{i_2}, ..., x_{i_s}) \in \mathcal{L}_2$. Then the following constants

$$\int_{\mathcal{K}^n} f^2(x) dx - f_0^2 = D \quad (9)$$

$$\int_0^1 ... \int_0^1 f_{i_1,i_2,...,i_s}^2(x_{i_1}, x_{i_2}, ..., x_{i_s}) dx_{i_1} dx_{i_2} ... dx_{i_s} = D_{i_1,i_2,...,i_s} \quad (10)$$

are termed as variances. Squaring equation 4, integrating over $\mathcal{K}^n$ and using the orthogonality property in equation 6, D evaluates to -

$$D = \widehat{\Sigma} D_{i_1,i_2,...,i_s} \quad (11)$$

Then the global sensitivity estimates is defined as -

$$S_{i_1,i_2,...,i_s} = \frac{D_{i_1,i_2,...,i_s}}{D} \quad (12)$$

It follows from equations 11 and 12 that

$$\widehat{\Sigma} S_{i_1,i_2,...,i_s} = 1 \quad (13)$$

Clearly, all sensitivity indices are non-negative, i.e an index $S_{i_1,i_2,...,i_s} = 0$ if and only if $f_{i_1,i_2,...,i_s} \equiv 0$. The true potential of Sobol indices is observed when variables $x_1, x_2, ..., x_n$ are divided into m different groups with $y_1, y_2, ..., y_m$ such that

$m < n$. Then $f(x) \equiv f(y_1, y_2, ..., y_m)$. All properties remain the same for the computation of sensitivity indices with the fact that integration with respect to y_k means integration with respect to all the x_i's in y_k. Details of these computations with examples can be found in Sobol[74]. Variations and improvements over Sobol indices have already been stated in section 2.1.

6.1.2 Density based indices

As discussed before, the issue with variance based methods is the high computational cost incurred due to the number of interactions among the variables. This further requires the use of screening methods to filter out redundant or unwanted factors that might not have significant impact on the output. Recent work by Da Veiga[57] proposes a new class of sensitivity indicies which are a special case of density based indicies Borgonovo[54]. These indicies can handle multivariate variables easily and relies on density ratio estimation. Key points from Da Veiga[57] are mentioned below.

Considering the similar notation in previous section, $f : \mathcal{R}^n \rightarrow \mathcal{R}$ ($u = f(x)$) is assumed to be continuous. It is also assumed that X_k has a known distribution and are independent. Baucells and Borgonovo[75] state that a function which measures the similarity between the distribution of U and that of $U|X_k$ can define the impact of X_k on U. Thus the impact is defined as -

$$S_{X_k} = \mathcal{E}(d(U, U|X_k)) \tag{14}$$

were $d(\cdot, \cdot)$ is a dissimilarity measure between two random variables. Here d can take various forms as long as it satisfies the criteria of a dissimilarity measure. Csiszár et al.[60]'s f-divergence between U and $U|X_k$ when all input random variables are considered to be absolutely continuous with respect to Lebesgue measure on $\mathcal{R}$ is formulated as -

$$d_F(U||U|X_k) = \int_{\mathcal{R}} F\left(\frac{p_U(u)}{p_{U|X_k}(u)}\right) p_{U|X_k}(u) du \tag{15}$$

were F is a convex function such that $F(1) = 0$ and p_U and $p_{U|X_k}$ are the probability distribution functions of U and $U|X_k$. Standard choices of F include Kullback-Leibler divergence $F(t) = -\log_e(t)$, Hellinger distance $(\sqrt{t} - 1)^2$, Total variation distance $F(t) = |t - 1|$, Pearson χ^2 divergence $F(t) = t^2 - 1$ and Neyman χ^2 divergence $F(t) = (1 - t^2)/t$. Substituting equation 15 in equation 14, gives the following sensitivity index -

$$
\begin{aligned}
S_{X_k}^F &= \int_{\mathcal{R}} d_F(U||U|X_k) p_{X_k}(x) dx \\
&= \int_{\mathcal{R}} \int_{\mathcal{R}} F\left(\frac{p_U(u)}{p_{U|X_k}(u)}\right) p_{U|X_k}(u) p_{X_k}(x) dx du \\
&= \int_{\mathcal{R}^2} F\left(\frac{p_U(u) p_{X_k}(x)}{p_{U|X_k}(u) p_{X_k}(x)}\right) p_{U|X_k}(u) p_{X_k}(x) dx du \\
&= \int_{\mathcal{R}^2} F\left(\frac{p_U(u) p_{X_k}(x)}{p_{X_k,U}(x, u)}\right) p_{X_k,U}(x, u) dx du \tag{16}
\end{aligned}
$$

were p_{X_k} and $p_{X_k,Y}$ are the probability distribution functions of X_k and (X_k, U), respectively. Csiszár et al.[60] f-divergences imply that these indices are positive and equate to 0 when U and X_k are independent. Also, given the formulation of $S_{X_k}^F$, it is invariant under any smooth and uniquely invertible transformation of the variables X_k and U (Kraskov et al.[76]). This has an advantage over Sobol sensitivity indices which are invariant under linear transformations.

By substituting the different formulations of F in equation 16, Da Veiga[57]'s work claims to be the first in establishing the link that previously proposed sensitivity indices are actually special cases of more general indices defined through Csiszár et al.[60]'s f-divergence. Then equation 16 changes to estimation of ratio between the joint density of (X_k, U) and the marginals, i.e -

$$S_{X_k}^F = \int_{\mathcal{R}^2} F\left(\frac{1}{r(x, u)}\right) p_{X_k,U}(x, u) dx du = \mathcal{E}_{(X_k,U)} F\left(\frac{1}{r(X_k, U)}\right) \tag{17}$$

were, $r(x, y) = (p_{X_k,U}(x, u))/(p_U(u) p_{X_k}(x))$. Multivariate extensions of the same are also possible under the same formulation.

Finally, given two random vectors $X \in \mathcal{R}^p$ and $Y \in \mathcal{R}^q$, the dependence measure quantifies the dependence between X and Y with the property that the measure equates to 0 if and only if X and Y are independent. These measures carry deep links (Sejdinovic et al.[77]) with distances between embeddings of distributions to reproducing kernel Hilbert spaces (RHKS) and here the related Hilbert-Schmidt independence criterion (HSIC by Gretton et al.[59]) is explained.

In a very brief manner from an extremely simple introduction by Daumé III[78] - "We first defined a field, which is a space that supports the usual operations of addition, subtraction, multiplication and division. We imposed an ordering on the field and described what it means for a field to be complete. We then defined vector spaces over fields, which are spaces that interact in a friendly way with their associated fields. We defined complete vector spaces and extended them to Banach spaces by adding a norm. Banach spaces were then extended to Hilbert spaces with the addition of a dot product." Mathematically, a Hilbert space $\mathcal{H}$ with elements $r, s \in \mathcal{H}$ has dot product $\langle r, s \rangle_{\mathcal{H}}$ and $r \cdot s$. When $\mathcal{H}$ is a vector space over a field $\mathcal{F}$, then the dot product is an element in $\mathcal{F}$. The product $\langle r, s \rangle_{\mathcal{H}}$ follows the below mentioned properties when $r, s, t \in \mathcal{H}$ and for all $a \in \mathcal{F}$ -

- Associative : $(ar) \cdot s = a(r \cdot s)$

- Commutative : $r \cdot s = s \cdot r$

- Distributive : $r \cdot (s + t) = r \cdot s + r \cdot t$

Given a complete vector space $\mathcal{V}$ with a dot product $\langle \cdot, \cdot \rangle$, the norm on $\mathcal{V}$ defined by $||r||_{\mathcal{V}} = \sqrt{(\langle r, r \rangle)}$ makes this space into a Banach space and therefore into a full Hilbert space.

A reproducing kernel Hilbert space (RKHS) builds on a Hilbert space $\mathcal{H}$ and requires all Dirac evaluation functionals in $\mathcal{H}$ are bounded and continuous (on implies the other). Assuming $\mathcal{H}$ is the $\mathcal{L}_2$ space of functions from X to $\mathcal{R}$ for some measurable X. For an element $x \in X$, a Dirac evaluation functional at x is a functional $\delta_x \in \mathcal{H}$ such that $\delta_x(g) = g(x)$. For the case of real numbers, x is a vector and g a function which maps from this vector space to $\mathcal{R}$. Then δ_x is simply a function which maps g to the value g has at x. Thus, δ_x is a function from $(\mathcal{R}^n \mapsto \mathcal{R})$ into $\mathcal{R}$.

The requirement of Dirac evaluation functions basically means (via the Riesz[79] representation theorem) if ϕ is a bounded linear functional (conditions satisfied by the Dirac evaluation functionals) on a Hilbert space $\mathcal{H}$, then there is a unique vector ℓ in $\mathcal{H}$ such that $\phi g = \langle g, \ell \rangle_{\mathcal{H}}$ for all $\ell \in \mathcal{H}$. Translating this theorem back into Dirac evaluation functionals, for each δ_x there is a unique vector k_x in $\mathcal{H}$ such that $\delta_x g = g(x) = \langle g, k_x \rangle_{\mathcal{H}}$. The reproducing kernel K for $\mathcal{H}$ is then defined as : $K(x, x') = \langle k_x, k_{x'} \rangle$, were k_x and $k_{x'}$ are unique representatives of δ_x and $\delta_{x'}$. The main property of interest is $\langle g, K(x, x') \rangle_{\mathcal{H}} = g(x')$. Furthermore, k_x is defined to be a function $y \mapsto K(x, y)$ and thus the reproducibility is given by $\langle K(x, \cdot), K(y, \cdot) \rangle_{\mathcal{H}} = K(x, y)$.

Basically, the distance measures between two vectors represent the degree of closeness among them. This degree of closeness is computed on the basis of the discriminative patterns inherent in the vectors. Since these patterns are used implicitly in the distance metric, a question that arises is, how to use these distance metric for decoding purposes?

The kernel formulation as proposed by Aizerman *et al.*[61], is a solution to our problem mentioned above. For simplicity, we consider the labels of examples as binary in nature. Let $\mathbf{x}_i \in \mathcal{R}^n$, be the set of n feature values with corresponding category of the example label (y_i) in data set $\mathcal{D}$. Then the data points can be mapped to a higher dimensional space $\mathcal{H}$ by the transformation ϕ:

$$\phi : \mathbf{x}_i \in \mathcal{R}^n \mapsto \phi(\mathbf{x}_i) \in \mathcal{H} \qquad (18)$$

This $\mathcal{H}$ is the *Hilbert Space* which is a strict inner product space, along with the property of completeness as well as separability. The inner product formulation of a space helps in discriminating the location of a data point w.r.t a separating hyperplane in $\mathcal{H}$. This is achieved by the evaluation of the inner product between the normal vector representing the hyperplane along with the vectorial representation of a data point in $\mathcal{H}$. Thus, the idea behind equation(18) is that even if the data points are nonlinearly clustered in space $\mathcal{R}^n$, the transformation spreads the data points into $\mathcal{H}$, such that they can be linearly separated in its range in $\mathcal{H}$.

Often, the evaluation of dot product in higher dimensional spaces is computationally expensive. To avoid incurring this cost, the concept of kernels in employed. The trick is to formulate kernel functions that depend on a pair of data points in the space $\mathcal{R}^n$, under the assumption that its evaluation is equivalent to a dot product in the higher dimensional space. This is given as:

$$\kappa(\mathbf{x}_i, \mathbf{x}_j) = < \phi(\mathbf{x}_i), \phi(\mathbf{x}_j) > \qquad (19)$$

Two advantages become immediately apparent. First, the evaluation of such kernel functions in lower dimensional space is computationally less expensive than evaluating the dot product in higher dimensional space. Secondly, it relieves the burden of searching an appropriate transformation that may map the data points in $\mathcal{R}^n$ to $\mathcal{H}$. Instead, all computations regarding discrimination of location of data points in higher dimensional space involves evaluation of the kernel functions in lower dimension. The matrix containing these kernel evaluations is referred to as the *kernel* matrix. With a cell in the kernel matrix containing a kernel evaluation between a pair of data points, the kernel matrix is square in nature.

As an example in practical applications, once the kernel has been computed, a pattern analysis algorithm uses the kernel function to evaluate and predict the nature of the new example using the general formula:

$$
\begin{aligned}
f(\mathbf{z}) &= \ <\mathbf{w}, \phi(\mathbf{z}) > + b \\
&= \ < \sum_{i=1}^{N} \alpha_i \times y_i \times \phi(\mathbf{x}_i), \phi(\mathbf{z}) > + b \\
&= \ \sum_{i=1}^{N} \alpha_i \times y_i \times < \phi(\mathbf{x}_i), \phi(\mathbf{z}) > + b \\
&= \ \sum_{i=1}^{N} \alpha_i \times y_i \times \kappa(\mathbf{x}_i, \mathbf{z}) + b
\end{aligned}
$$

$$(20)$$

where $\mathbf{w}$ defines the hyperplane as some linear combination of training basis vectors, $\mathbf{z}$ is the test data point, y_i the class label for training point $\mathbf{x}_i$, α_i and b are the constants. Various transformations to the kernel function can be employed, based on the properties a kernel must satisfy. Interested readers are referred to Taylor and Cristianini[80] for description of these properties in detail.

The Hilbert-Schmidt independence criterion (HSIC) proposed by Gretton *et al.*[59] is based on kernel approach for finding dependences and on cross-covariance operators in RKHS. Let $X \in \mathcal{X}$
Fig. 7 A geometrical interpretation of mapping nonlinearly separable data into higher dimensional space where it is assumed to be linearly separable, subject to the holding of dot product.

have a distribution P_X and consider a RKHS $\mathcal{A}$ of functions $\mathcal{X} \to \mathcal{R}$ with kernel $k_{\mathcal{X}}$ and dot product $\langle \cdot, \cdot \rangle_{\mathcal{A}}$. Similarly, Let $U \in \mathcal{Y}$ have a distribution P_Y and consider a RKHS $\mathcal{B}$ of functions $\mathcal{U} \to \mathcal{R}$ with kernel $k_{\mathcal{B}}$ and dot product $\langle \cdot, \cdot \rangle_{\mathcal{B}}$. Then the cross-covariance operator $C_{X,U}$ associated with the joint distribution P_{XU} of (X, U) is the linear operator $\mathcal{B} \to \mathcal{A}$ defined for every $a \in \mathcal{A}$ and $b \in \mathcal{B}$ as -

$$\langle a, C_{X \cup U} b \rangle_{\mathcal{A}} = \mathcal{E}_{XU}[a(X), b(U)] - \mathcal{E}_X a(X)\mathcal{E}_U b(U) \quad (21)$$

The cross-covariance operator generalizes the covariance matrix by representing higher order correlations between X and U through nonlinear kernels. For every linear operator $C : \mathcal{B} \to \mathcal{A}$ and provided the sum converges, the Hilbert-Schmidt norm of C is given by -

$$\|C\|_{HS}^2 = \Sigma_{k,l} \langle a_k, C b_l \rangle_{\mathcal{A}} \quad (22)$$

were a_k and b_l are orthonormal bases of $\mathcal{A}$ and $\mathcal{B}$, respectively. The HSIC criterion is then defined as the Hilbert-Schmidt norm of cross-covariance operator -

$$HSIC(X, U)_{\mathcal{A},\mathcal{B}} = \begin{cases} \|C_{XU}\|_{HS}^2 = \\ \mathcal{E}_{X,X',U,U'} k_{\mathcal{X}}(X, X') k_{\mathcal{U}}(U, U') + \\ \mathcal{E}_{X,X'} k_{\mathcal{X}}(X, X') \mathcal{E}_{U,U'} k_{\mathcal{U}}(U, U') - \\ 2\mathcal{E}_{X,Y}[\mathcal{E}_{X'} k_{\mathcal{X}}(X, X') \mathcal{E}_{U'} k_{\mathcal{U}}(U, U')] \end{cases} \quad (23)$$

were the equality in terms of kernels is proved in Gretton *et al.*[59]. Finally, assuming (X_i, U_i) $(i = 1, 2, \ldots, n)$ is a sample of the random vector (X, U) and denote $K_{\mathcal{X}}$ and $K_{\mathcal{U}}$ the Gram matrices with entries $K_{\mathcal{X}}(i, j) = k_{\mathcal{X}}(X_i, X_j)$ and $K_{\mathcal{U}}(i, j) = k_{\mathcal{U}}(U_i, U_j)$. Gretton *et al.*[59] proposes the following estimator for $HSIC_n(X, U)_{\mathcal{A},\mathcal{B}}$ -

$$HSIC_n(X, U)_{\mathcal{A},\mathcal{B}} = \frac{1}{n^2} Tr(K_{\mathcal{X}} H K_{\mathcal{U}} H) \quad (24)$$

were H is the centering matrix such that $H(i, j) = \delta_{i,j} - \frac{1}{n}$. Then $HSIC_n(X, U)_{\mathcal{A},\mathcal{B}}$ can be expressed as -

$$HSIC(X, U)_{\mathcal{A},\mathcal{B}} = \begin{cases} \frac{1}{n^2} \Sigma_{i,j=1}^n k_{\mathcal{X}}(X_i, X_j) k_{\mathcal{U}}(U_i, U_j) \\ + \frac{1}{n^2} \Sigma_{i,j=1}^n k_{\mathcal{X}}(X_i, X_j) \frac{1}{n^2} \Sigma_{i,j=1}^n k_{\mathcal{U}}(U_i, U_j) \\ - \frac{2}{n} \Sigma_{i=1}^n [\frac{1}{n} \Sigma_{j=1}^n k_{\mathcal{X}}(X_i, X_j) \frac{1}{n} \Sigma_{j=1}^n k_{\mathcal{U}}(U_i, U_j)] \end{cases} \quad (25)$$

Finally, Da Veiga[57] proposes the sensitivity index based on distance correlation as -

$$S_{X_k}^{HSIC_{\mathcal{A},\mathcal{B}}} = R(X_k, U)_{\mathcal{A},\mathcal{B}} \quad (26)$$

were the kernel based distance correlation is given by -

$$R^2(X, U)_{\mathcal{A},\mathcal{B}} = \frac{HSIC(X, U)_{\mathcal{A},\mathcal{B}}}{\sqrt{(HSIC(X, X)_{\mathcal{A},\mathcal{A}} HSIC(U, U)_{\mathcal{B},\mathcal{B}})}} \quad (27)$$

were kernels inducing $\mathcal{A}$ and $\mathcal{B}$ are to be chosen within a universal class of kernels. Similar multivariate formulation for equation 24 are possible.

6.1.3 Choice of sensitivity indices

The SENSITIVITY PACKAGE (Faivre *et al.*[81] and Iooss and Lemaître[22]) in R langauge provides a range of functions to compute the indices and the following indices will be taken into account for addressing the posed questions in this manuscript.

1. sensiFdiv - conducts a density-based sensitivity analysis where the impact of an input variable is defined in terms of dissimilarity between the original output density function and the output density function when the input variable is fixed. The dissimilarity between density functions is measured with Csiszar f-divergences. Estimation is performed through kernel density estimation and the function kde of the package ks. (Borgonovo[54], Da Veiga[57])

2. sensiHSIC - conducts a sensitivity analysis where the impact of an input variable is defined in terms of the distance between the input/output joint probability distribution and the product of their marginals when they are embedded in a Reproducing Kernel Hilbert Space (RKHS). This distance corresponds to HSIC proposed by Gretton *et al.*[59] and serves as a dependence measure between random variables.

3. soboljansen - implements the Monte Carlo estimation of the Sobol indices for both first-order and total indices at the same time (all together 2p indices), at a total cost of (p+2) × n model evaluations. These are called the Jansen estimators. (Jansen[49] and Saltelli et al.[41])

4. sobol2002 - implements the Monte Carlo estimation of the Sobol indices for both first-order and total indices at the same time (all together 2p indices), at a total cost of (p+2) ×n model evaluations. These are called the Saltelli estimators. This estimator suffers from a conditioning problem when estimating the variances behind the indices computations. This can seriously affect the Sobol indices estimates in case of largely non-centered output. To avoid this effect, you have to center the model output before applying "sobol2002". Functions "soboljansen" and "sobolmartinez" do not suffer from this problem. (Saltelli[35])

5. sobol2007 - implements the Monte Carlo estimation of the Sobol indices for both first-order and total indices at the same time (all together 2p indices), at a total cost of (p+2) × n model evaluations. These are called the Mauntz estimators. (Saltelli and Annoni[48])

6. sobolmartinez - implements the Monte Carlo estimation of the Sobol indices for both first-order and total indices using correlation coefficients-based formulas, at a total cost of (p + 2) × n model evaluations. These are called the Martinez estimators.

7. sobol - implements the Monte Carlo estimation of the Sobol sensitivity indices. Allows the estimation of the indices of the variance decomposition up to a given order, at a total cost of (N + 1) × n where N is the number of indices to estimate. (Sobol'[21])

7 Optimization and Support Vector Machines

Aspects of SVMs from Sinha[82] are reproduced for completeness.

7.1 Optimization Problems

7.1.1 Introduction

The main focus in this section is optimization problems, the concept of Lagrange multipliers and KKT conditions, which will be later used to explain the details about the SVMs.

7.1.2 Mathematical Formulation

Optimization problems arise in almost every area of engineering. The goal is to achieve an almost perfect and efficient result, while carrying out certain procedures of optimization. Our main source

of reference on this topic derives from Bletzinger[83]. We will be using notations used in Bletzinger[83]. In mathematical terms the general form of optimization problem can be represented as :

$$
\begin{aligned}
\text{minimize} \quad &: \quad f(\mathbf{x}); \ \mathbf{x} \in \mathbf{R}^n \\
\text{such that} \quad &: \quad g_j(\mathbf{x}) \leq 0; \ j = 1,.....,p \quad (28) \\
&: \quad h_j(\mathbf{x}) = 0; \ j = 1,.....,q.
\end{aligned}
$$

where f, g_j and h_j are the objective function, equality constraints and inequality constraints. Generally, the number of constraints is less than the number of variables used to formulate the optimization problem. For a problem to be linear, both the constraints and the objective function need to be linear. Quadratic problems require only the objective function to be quadratic, while the constraints remain linear in formulation. Besides these, if any one of the functions is nonlinear, then the problem becomes nonlinear in nature. A graphical view of the types of the problems can be seen in fig. 8).

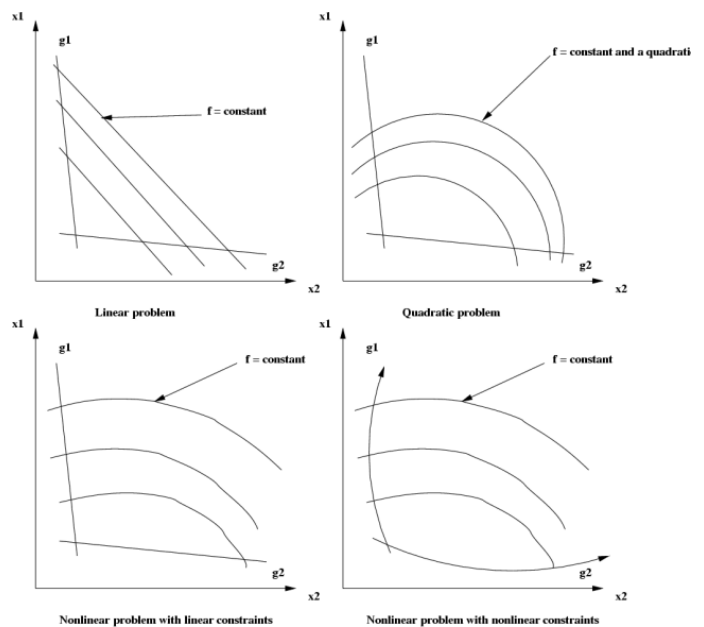

Fig. 8 Kinds of optimization problems.

7.1.3 Lagrange Multipliers

In unconstrained optimization problems, where the first order derivatives are assumed continuous, the solution is found by solving:

$$
\nabla_x f = \frac{\partial f}{\partial x_i} = 0; \ i = 1,.....,n. \quad (29)
$$

where f is a function of $\mathbf{x}$. Since most of the optimization problems are constrained, the concept of Lagrange multipliers is introduced in order to solve the problem. Thus, the Lagrangian

formulation, for Eqn. 28 becomes:

$$L(\mathbf{x}, \lambda, \mu) = f(\mathbf{x}) + \sum_{j=1}^{p} \lambda_j g_j(\mathbf{x}) + \sum_{j=1}^{q} \mu_j h_j(\mathbf{x}) \qquad (30)$$

where L is the Lagrangian, λ and μ are the vectors of the Lagrange multipliers for inequality and equality constraints, respectively.

Next comes the solving of the Lagrangian. We try to derive a solution in terms of variables used and show that the final solution achieved by Equ. 28 and Eqn. 30 remains the same. For the sake of derivation, we assume that each of the vectors $\mathbf{x}$, λ and μ have a single element and also there exists a single optimal solution. We will then generalize the solution to vectors containing various elements. Let $\mathbf{x}^*$, λ^* and μ^* be the optimal solution for the Lagrangian. Let $\mathbf{x}^!$ be the optimal solution for $f(\mathbf{x})$. To begin with, our Lagrangian has the form:

$$L(x, \lambda, \mu) = f(x) + \lambda g(x) + \mu h(x) \qquad (31)$$

Derivation:

- **Step 1:** Differentiate the Lagrangian in Eqn 31 w.r.t x and equate it to zero.

$$\frac{\partial L}{\partial x} = \frac{\partial f}{\partial x} + \lambda \frac{\partial g}{\partial x} + \mu \frac{\partial h}{\partial x} = 0 \qquad (32)$$

- **Step 2:** Find x in terms of λ and μ, such that $x = x(\lambda, \mu)$.

- **Step 3:** Differentiate the Lagrangian in Eqn. 31 w.r.t λ and equate it to zero.

$$\frac{\partial L}{\partial \lambda} = g(x) = 0 \qquad (33)$$

- **Step 4:** Differentiate the Lagrangian in Eqn 31 w.r.t μ and equate it to zero.

$$\frac{\partial L}{\partial \mu} = h(x) = 0 \qquad (34)$$

- **Step 5:** Substitute $x(\lambda, \mu)$ in Equ. 33 and Eqn. 34 to get two equations in two unknowns λ and μ and solve to get the optimal values.

$$g(x(\lambda, \mu)) = 0 \qquad (35)$$

$$h(x(\lambda, \mu)) = 0 \qquad (36)$$

Let λ^*, μ^* be the solution. Substituting these in $x = x(\lambda, \mu)$, we get x^*.

- **Step 6:** Combining Eqn. 33 and Eqn. 34 in Eqn. 31, along

with λ^*, μ^* and x^*, we have:

$$L(x^*, \lambda^*, \mu^*) = f(x^*) + \lambda^* g(x^*) + \mu^* h(x^*) = f(x^*) \qquad (37)$$

Since, it is assumed that there exist only one optimal solution we have:

$$\begin{aligned} L(x^*, \lambda^*, \mu^*) &= f(x^*) = f(x^!) \\ x^* &= x^! \end{aligned} \qquad (38)$$

Lastly, since $g(x)$ in Eqn. 33 is a inequality constraint, we have:

$$\begin{aligned} \lambda g(x) &= 0 \\ \lambda &\geq 0 \end{aligned} \qquad (39)$$

7.1.4 Dual Functions

For sake of simplicity, let us for a moment ignore the equality constraint. Then the Lagrangian becomes:

$$L(x, \lambda, \mu) = f(x) + \lambda g(x). \qquad (40)$$

It is sometimes easy to transform the Lagrangian into a simpler form, in order to find an optimal solution. We can represent the Lagrangian as a Dual function in such a manner that the optimal solution defined as minimum of $L(x, \lambda^*)$ w.r.t x where $\lambda = \lambda^*$, can be represented as the maximum of dual function $D(\lambda)$ w.r.t λ. For a given λ, the dual is evaluated by finding the minimum of $L(x, \lambda)$ w.r.t x. Thus to find the optimal point we evaluate:

$$\max_{\lambda} D(\lambda) = \min_{x} L(x, \lambda^*) \qquad (41)$$

So the basic steps to solve the dual problem are as follows: **Step 1:** Minimize $L(x, \lambda)$ w.r.t x, and find x in terms of λ. **Step 2:** Substitute $x(\lambda)$ in L s.t. $D(\lambda) = L(x(\lambda), \lambda)$. **Step 3:** Maximize $D(\lambda)$ w.r.t λ.

7.1.5 Karush Kuhn Tucker Conditions

The derivation in the last part (Eqn. 31 to Eqn. 39)gives us a set of equations that need to be evaluated along with the consideration of constraints present. These set of equations and constraints in terms of the Lagrangian, form the Karush Kuhn Tucker Conditions. We give here the generalized KKT conditions and explain the necessary details.

$$\begin{aligned} \frac{\partial L}{\partial x_i} = \frac{\partial f}{\partial x_i} + \sum_{j=1}^{p} \lambda_j \frac{\partial g_j}{\partial x_i} + \sum_{j=1}^{p} \mu_j \frac{\partial h_j}{\partial x_i} = 0 &\quad : \quad i = 1, \ldots, n \\ \frac{\partial L}{\partial \lambda_j} = g_j(\mathbf{x}) = 0 &\quad : \quad j = 1, \ldots, p \\ \frac{\partial L}{\partial \mu_j} = h_j(\mathbf{x}) = 0 &\quad : \quad j = 1, \ldots, q \\ \lambda_j g_j = 0 &\quad : \quad j = 1, \ldots, p \\ \lambda_j \geq 0 &\quad : \quad j = 1, \ldots, p \end{aligned} \qquad (42)$$

where L is Eqn. 30.

The KKT conditions specify a few points which are as follows:
Fig. 9 Linear hyperplane for separable data. Adapted from Burges (A Tutorial on Support Vector Machines)

1. The first line states that the linear combination of objective and constraint gradients vanishes.

2. A prerequisite of the KKT conditions is that the gradients of the constraints must be continuous (evident from second and third lines in Eqn. 42).

3. The last two lines in Eqn. 42 state that at optimum either the constraints are active or the constrains are inactive.

7.2 Support Vector Machines

Armed with the knowledge of optimization problems and concept of Lagrange multipliers, we now delve into the workings of support vector machines. Burges[84] provides a good introduction to SVMs and is our main reference. Interested readers should refer to Cristianini and Shawe-Taylor[85], Schölkopf and Smola[86] and Vapnik and Vapnik[87] for detailed references.

7.2.1 Separable Case

Let us suppose that we are presented with a data set that is linearly separable. We assume that there are m examples of data in the format $\{\mathbf{x}_i, y_i\}$, s.t. $\mathbf{x}_i \in \mathbf{R}^n$; $i = 1, \ldots, m$, where $y_i \in \{-1, 1\}$ is the corresponding true label of $\mathbf{x}_i$. We also suppose there is an existence of a linear hyperplane in the n dimensional space that separates the positively labeled data from the negatively labeled data. Let this separating hyperplane be given by

$$\mathbf{w} \cdot \mathbf{x} + b = 0. \tag{43}$$

where, $\mathbf{w}$ is the normal vector $\perp$ to the hyperplane and $|b|/||\mathbf{w}||$ is the shortest perpendicular distance of the hyperplane to the

origin. $||\mathbf{w}||$ is the Euclidean norm of $\mathbf{w}$. The *margin* of a hyperplane is then defined as the minimum of the distance of the positively and negatively labeled examples, to the hyperplane. For the linear case, the SVM searches for the hyperplane with largest margin. We now have three conditions, based on the location of an example $\mathbf{x}_i$ w.r.t the hyperplane:

$$\mathbf{w} \cdot \mathbf{x}_i + b = 0 \quad : \quad \text{example lying on the hyperplane.} \tag{44}$$

$$\mathbf{w} \cdot \mathbf{x}_i + b \geq +1 \quad : \quad \text{positively labeled example.} \tag{45}$$

$$\mathbf{w} \cdot \mathbf{x}_i + b \leq -1 \quad : \quad \text{negatively labeled example.} \tag{46}$$

Combining the equality and the two inequalities we have:

$$y_i(\mathbf{w} \cdot \mathbf{x}_i + b) - 1 \geq 0 \tag{47}$$

Since the SVMs search for the largest margin, we now try to find a mathematical expression of the margin. Considering the examples that satisfy equality in Eqn. 45, the distance of the closest positive example can be expressed as $|1 - b|/||\mathbf{w}||$. Similarly, considering the negative examples that satisfy equality in Eqn. 46, the distance of the closest negative example can be expressed as $|-1 - b|/||\mathbf{w}||$. On summation of the two shortest distances, we get the margin of the hyperplane as $2/||\mathbf{w}||$. Since the labels are $\{-1, 1\}$, no example lies inside the hyperplanes representing the margin in this case. Taking into account that the SVM searches for the largest margin, we can say that it can be achieved by minimizing $||\mathbf{w}||^2$, subject to the constraints in Eqn. 47. Examples lying on the hyperplanes of the margins are termed *support vectors*, as their removal would change the margin and thus the solution. Figure 9 represents the conceptual points about separating hyperplanes.

7.3 Lagrangian Representation: Separable Case

Clearly, the previous paragraph shows that finding the margin is a problem of optimization as the goal is to minimize $||\mathbf{w}||^2$ subject to constraints in Eqn. 47. Employing the ideas of Chapter 3, the Lagrangian for the above problem, is:

$$L(\mathbf{w}, b, \alpha) = \frac{1}{2}||\mathbf{w}||^2 - \sum_{i=1}^{m} \alpha_i y_i(\mathbf{x}_i \cdot \mathbf{w} + b) + \sum_{i=1}^{m} \alpha_i \tag{48}$$

where $\frac{1}{2}||\mathbf{w}||^2$ is the objective function, α is the Lagrangian multiplier and the Eqn. 47 is the inequality constraint. Since the minimization of the objective function is required, we employ the ideas of the derivation of KKT conditions (Eqn. 42) to Eqn. 48. In short, we would require the $L(\mathbf{w}, b, \alpha)$ to be minimized w.r.t $\mathbf{w}$ and b and also require its derivative w.r.t all α_i's to vanish. Thus
Fig. 10 Linear hyperplane for nonseparable data. Adapted from Burges (A Tutorial on Support Vector Machines)

the KKT conditions take the form:

$$
\begin{array}{ll}
\frac{\partial L}{\partial w_j} = w_j - \sum_i \alpha_i y_i x_{ij} = 0 & : \quad j = 1,....,n \\
\frac{\partial L}{\partial b} = -\sum_{i=1}^{m} \alpha_i y_i = 0 & : \quad i = 1,....,m \\
\frac{\partial L}{\partial \alpha_i} = -\sum_{i=1}^{m} y_i(\mathbf{x}_i \cdot \mathbf{w} + b) + \sum_{i=1}^{m} 1 = 0 & : \quad i = 1,....,m \\
\alpha_i(y_i(\mathbf{x}_i \cdot \mathbf{w} + b) - 1) = 0 & : \quad i = 1,....,m \\
\alpha_i \geq 0 & : \quad i = 1,....,m
\end{array}
\tag{49}
$$

Thus solving the SVMs is equivalent to solving the KKT conditions. While $\mathbf{w}$ is determined by the training set, b can be found by solving the penultimate equation in Eqn. 49 for which $\alpha_i \neq 0$. Also note that examples that have $\alpha_i \neq 0$ form the set of support vectors.

The dual problem for the same Lagrangian is:

$$
D = \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j \mathbf{x}_i \cdot \mathbf{x}_j
\tag{50}
$$

Solving for Eqn. 50 requires maximization of D w.r.t α_i, subject to second line of Eqn. 49 and positivity of α_i, with the solution given by first line of Eqn. 49.

To classify or predict the label of a new example $\mathbf{x}_{new}$, the SVM has to evaluate $(\mathbf{x}_{new} \cdot \mathbf{w} + b)$ and check the sign of the evaluated value. A positive sign would lead to assignment of a $+1$ label and a negative sign to -1.

7.4 Nonseparable Case

For many classification problems, the data present is nonseparable. To extend the idea to nonseparable case, some amount of

cost is added, which takes care of particular cases of examples. This is achieved by introducing slack in the constraints Eqn. 45 and Eqn. 46 (Burges[84], Vapnik and Vapnik[87]). The equations then becomes

$$
\mathbf{w} \cdot \mathbf{x}_i + b \geq 1 - \xi_i \quad : \quad \text{positively labeled example.} \tag{51}
$$

$$
\mathbf{w} \cdot \mathbf{x}_i + b \leq -1 + \xi_i \quad : \quad \text{negatively labeled example.} \tag{52}
$$

For an error to occur, the ξ_i value must exceed unity. To take care of the cost of errors, a penalty is introduced which changes the objective function from $||\mathbf{w}||^2/2$ to $||\mathbf{w}||^2/2 + C(\sum_i \xi_i)^k$. Thus $\sum_i \xi_i$ represents the upper bound on the training error. For quadratic problems, k can be 1 or 2.

7.5 Lagrangian Representation: Nonseparable Case

Since the formulation of the Lagrangian and its dual follow the same procedure, as mentioned before, we only mention the equations. The Lagrangian for nonlinear nonseparable case is:

$$
\begin{aligned}
L(\mathbf{w}, b, \alpha, \xi) = & \frac{1}{2}||\mathbf{w}||^2 + C\sum_{i=1}^{m} \xi_i - \sum_{i=1}^{m} \alpha_i \{y_i(\mathbf{x}_i \cdot \mathbf{w} + b) \\
& -1 + \xi_i\} - \sum_{i=1}^{m} \mu_i \xi_i
\end{aligned}
\tag{53}
$$

The corresponding KKT conditions are:

$$
\begin{array}{ll}
\frac{\partial L}{\partial w_j} = w_j - \sum_i \alpha_i y_i x_{ij} = 0 & : \quad j = 1,\ldots,n \\
\frac{\partial L}{\partial b} = -\sum_{i=1}^{m} \alpha_i y_i = 0 & : \quad i = 1,\ldots,m \\
\frac{\partial L}{\partial \alpha_i} = y_i(\mathbf{x}_i \cdot \mathbf{w} + b) - 1 + \xi_i = 0 & : \quad i = 1,\ldots,m \\
\frac{\partial L}{\partial \xi_i} = C - \alpha_i - \mu_i = 0 & : \quad i = 1,\ldots,m \\
\alpha_i \{y_i(\mathbf{x}_i \cdot \mathbf{w} + b) - 1 + \xi_i\} = 0 & : \quad i = 1,\ldots,m \\
\mu_i \xi_i = 0 & : \quad i = 1,\ldots,m \\
\alpha_i \geq 0 & : \quad i = 1,\ldots,m \\
\xi_i \geq 0 & : \quad i = 1,\ldots,m \\
\mu_i \geq 0 & : \quad i = 1,\ldots,m
\end{array}
\tag{54}
$$

The dual formulation $k = 1$ for the Lagrangian just discussed is:

$$
D = \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j \mathbf{x}_i \cdot \mathbf{x}_j
\tag{55}
$$

All the previous conditions remain same, except that the Lagrangian multiplier α_i now has a upper bound of value C. The solution for the dual is given by $\mathbf{w} = \sum_{i=1}^{N_s} \alpha_i y_i \mathbf{x}_i$. N_s is the number of support vectors. Figure 10 depicts the nonseparable case.

7.6 Kernels and Space Dimensionality Transformation

The above cases were for linear separating hyperplanes. In order to generalize for nonlinear cases, Boser et.al[88] employed the idea of Aizerman[61] as follows; Since the Dual in Eqn. 55 and its corresponding constraint equations employ the dot product of the examples, $\mathbf{x}_i \cdot \mathbf{x}_j$, it was proposed to map the data in a higher dimensional space using a function ϕ s.t. the algorithm would depend only on dot products in the higher space. Next, the existence of a function called *kernel*, dependent on $\mathbf{x}_i$ and $\mathbf{x}_j$, was assumed s.t. the value reported by the kernel was equal to the value resulting from the dot product in the higher space. A mathematical representation of the above concept is -

$$\phi : \mathbf{R}^n \mapsto H \tag{56}$$

$$K(\mathbf{x}_i, \mathbf{x}_j) = \phi(\mathbf{x}_i) \cdot \phi(\mathbf{x}_j) \tag{57}$$

where H is a higher dimensional space.

This technique drastically reduces the amount of work required while dealing with nonlinear separating hyperplanes, concerning search for appropriate ϕ. Instead, one only works with $K(\mathbf{x}_i, \mathbf{x}_j)$, in place of $\mathbf{x}_i \cdot \mathbf{x}_j$. For classification purpose, where the sign of the function $(\mathbf{x}_{new} \cdot \mathbf{w} + b)$ is evaluated, the formulation employing kernels become:

$$\begin{aligned} f(\mathbf{x}_{new}) &= (\mathbf{w} \cdot \mathbf{x}_{new} + b) \\ &= \sum_{i=1}^{N_s} \alpha_i y_i \phi(\mathbf{s}_i) \cdot \phi(\mathbf{x}_{new}) + b \\ &= \sum_{i=1}^{N_s} \alpha_i y_i K(\mathbf{s}_i, \mathbf{x}_{new}) + b \end{aligned} \tag{58}$$

where $\mathbf{s}_i$ are the support vectors.
