24 **Running title:**

25 DISCOMARK - Phylogenetic marker development

26 **Abstract**

27 High-throughput sequencing has laid the foundation for fast and cost-effective development
28 of phylogenetic markers. Here we present the program DISCOMARK, which streamlines the
29 development of nuclear DNA (nDNA) markers from whole-genome (or whole-transcriptome)
30 sequencing data, combining local alignment, alignment trimming, reference mapping and
31 primer design based on multiple sequence alignments in order to design primer pairs from
32 input orthologous sequences. In order to demonstrate the suitability of DISCOMARK we
33 designed markers for two groups of species, one consisting of closely related species and one
34 group of distantly related species. For the closely related members of the species complex of
35 *Cloeon dipterum* s.l. (Insecta, Ephemeroptera), the program discovered a total of 78 markers.
36 Among these, we selected eight markers for amplification and Sanger sequencing. The exon
37 sequence alignments (2,526 base pairs (bp)) were used to reconstruct a well supported
38 phylogeny and to infer clearly structured haplotype networks. For the distantly related species
39 we designed primers for several families in the insect order Ephemeroptera, using available
40 genomic data from four sequenced species. We developed primer pairs for 23 markers that are
41 designed to amplify across several families. The DISCOMARK program will enhance the
42 development of new nDNA markers by providing a streamlined, automated approach to
43 perform genome-scale scans for phylogenetic markers. The program is written in Python,
44 released under a public license (GNU GPL v2), and together with a manual and example data
45 set available at: <https://github.com/hdetering/discomark>.

46 **Introduction**

47 The inference of phylogenetic relationships has benefited profoundly from the availability of
48 nuclear DNA (nDNA) sequences for an increasing number of organism groups. The
49 development of new phylogenetic markers has provided unprecedented insight into the
50 evolutionary relationships of non-model organisms in particular (Ellegren 2014). Large sets of
51 nDNA markers (single copy genes) have recently been designed for taxonomic groups for
52 which genomic resources were available, e.g. cichlid fish (Meyer *et al.* 2015), ray-finned fish
53 (Near *et al.* 2012), reptiles (Ruane *et al.* 2014), birds (Kerr *et al.* 2014) and flowering plants
54 (Zeng *et al.* 2014). However, for many taxonomic groups there are only a handful of nDNA
55 markers available that are suitable for phylogenetic reconstruction. Other approaches, such as
56 ultra-conserved element (UCE) sequencing (Faircloth *et al.* 2012), anchored hybrid
57 enrichment (Lemmon and Lemmon 2012), restriction site-associated DNA (RAD) sequencing
58 (Baird *et al.* 2008) or genotyping by sequencing (GBS, Elshire *et al.* 2011) have become
59 popular for addressing specific questions in systematics or population genetics; however,
60 these methods are still cost-intensive, require a comparatively high amount of starting DNA
61 material and can depend on the availability of reference genomes (e.g. anchored hybrid
62 enrichment). Consequently, standard Sanger sequencing approaches are still in high demand
63 for various research questions.

64 Identification of novel phylogenetic markers has been a predominantly manual process,
65 which impedes their large-scale development, and comprehensive primer design based on
66 large sets of multiple sequence alignments remains challenging. Existing tools can generally
67 be classified into those developed for primer design or for marker discovery. Primer design
68 tools can design primer pairs for single loci (e.g. GEMI, Sobhy *et al.* 2012; PRIMER3,
69 Untergasser *et al.* 2012; CEMASUITE, Lane *et al.* 2015) or multiple loci at once

70 (BATCHPRIMER3, You *et al.* 2008; PRIMERVIEW, O'Halloran 2015). Some programs are
71 specific for highly variable DNA targets (PRIMERDESIGN, Brodin *et al.* 2013; PRIMERDESIGN-
72 M, Yoon and Leitner 2015), viral genomes (PRISM, Yu *et al.* 2015), and transcriptome input
73 data (SCRIMER, Morkovsky *et al.* 2015). Marker discovery tools target single nucleotide
74 polymorphism (SNP) markers in polyploid organisms (POLYMARKER, Ramirez-Gonzalez *et*
75 *al.* 2015), and putative single copy loci from plant transcriptomes (MARKERMINER, Chamala
76 *et al.* 2015). The challenge of developing new phylogenetic markers lies both in the discovery
77 of conserved regions, the design of primer pairs and an estimation of the level of their
78 phylogenetic signal.

79 Here we present DISCOMARK (=Discovery of Markers), a flexible, user-friendly program
80 that identifies conserved regions and designs primers based on multiple sequence alignments
81 taken from FASTA-formatted files of putative orthologous sequences from whole-genome or
82 whole-transcriptome data. The program can be used to easily screen for phylogenetically
83 suitable nDNA markers and to design primers that can be used for Sanger sequencing as well
84 as high-throughput sequencing. The program is structured into several steps that can be
85 individually optimized by the user and run independently. In terms of input, the program can
86 be applied on large and small sets of taxa, including both closely and distantly related species.
87 Ideally, orthologous sequences in combination with a whole-genome reference sequence are
88 used. Thus, exon/intron boundaries can be inferred using the reference for each marker. Under
89 the default settings, the program will design several primer pairs that anneal in conserved
90 regions. The visualization of the alignments with potential primers allows the user to choose
91 between primers targeting exons or introns (e.g. exon-primed intron-crossing (EPIC)
92 markers). Additionally, information about the suitability as phylogenetic markers is provided
93 by an estimate of the number of SNPs per marker and the applicability across species. Finally,

94 we demonstrate the utility of DISCOMARK for (1) closely related species (i.e. *Cloeon dipterum*
95 s.l. species complex) using whole-genome data, and (2) distantly related species (i.e. insect
96 order Ephemeroptera) using whole-genome data derived from genome sequencing projects. In
97 order to generate genomic reference sequences we used draft whole genome sequencing at
98 shallow coverage followed by draft genome assembly. In one scenario (*C. dipterum* s.l.
99 species complex) we demonstrate that incomplete genomic data can be used for ortholog
100 prediction and primer design as well.

101 **Materials and Methods**

102 *DISCOMARK implementation*

103 The program DISCOMARK is written in Python and was developed to design primer pairs in
104 conserved regions of predicted orthologous genes. Orthologs are required for phylogenetic
105 studies. The ortholog identification step is not part of the DISCOMARK workflow but
106 DISCOMARK is designed to directly work with the output of several ortholog prediction
107 programs, e.g. HAMSTR (Ebersberger *et al.* 2009), or Orthograph
108 (<https://github.com/mptksen/Orthograph>, last accessed March 25, 2016). Orthologous groups
109 may be derived from genome or transcriptome sequence data. In addition to the orthologous
110 genes, genomic data such as whole-genome sequencing data can be provided to DISCOMARK
111 as a guide to detect exon/intron boundaries. DISCOMARK performs seven steps, combining
112 Python scripts with widely used bioinformatics programs (Fig. 1). The steps: (1) combine
113 orthologous groups of sequences, (2) align sequences of each orthologous group using
114 MAFFT v.7.205 (Katoh and Standley 2013), (3) trim sequence alignments with TRIMAL v.1.4
115 (Capella-Gutierrez *et al.* 2009), (4) align sequences against a reference (e.g. whole-genome
116 dataset from the same or closely related taxa) with BLASTN v.2.2.29 (Altschul *et al.* 1997;

117 Camacho *et al.* 2009) and re-alignment using MAFFT, (5) design primer pairs on single-gene
118 alignments using a modified version of PRIFi (Fredslund *et al.* 2005), adapted by us into a
119 Python package that uses BioPython v.1.65 and Python v.3.4.3, (6) check primer specificity
120 with BLASTN, and (7) generate output in several formats (visual HTML report, tabular data
121 and FASTA files of the primers). The results of each step can be inspected in the respective
122 output folders.

123 *1. Combine sequences.* In the first step, the putative orthologous sequences of different taxa
124 are combined according to the orthologous groups. The input files are expected to be
125 nucleotide sequences in FASTA format. We recommend using putative orthologous exon
126 sequences (e.g. CDS) in combination with whole-genome data (e.g. a draft genome
127 assembly). Each input file is expected to contain the sequences of one orthologous group;
128 orthologs of each input taxon are to be organized into a taxon folder. Importantly, file names
129 represent the ortholog identifiers used to combine orthologous sequences of the various input
130 taxa; by default, ortholog prediction tools follow that convention.

131 *2. Align sequences.* Orthologous sequences combined according to the orthologous groups are
132 separately aligned with the multiple sequence alignment (MSA) program MAFFT. Alignment
133 parameters can be specified by the user via a configuration file (discomark.conf, located in the
134 program folder). Default parameters are the following: ‘--localpair --maxiterate 16 --
135 inputorder --preserve-case --quiet’ (L-INS-i alignment method). We chose MAFFT as multiple
136 alignment tool because it combines accuracy and efficiency and has been adopted widely in
137 the scientific community (Pais *et al.* 2014; Szitenberg *et al.* 2015).

138 *3. Trim alignments.* In order to remove poorly aligned regions, sequence alignments are
139 trimmed using TRIMAL. The program TRIMAL analyzes the distribution of gaps and

140 mismatches in the alignment and discard alignment positions and sequences of low quality.
141 By default, DISCOMARK calls TRIMAL with the ‘-strictplus’ method. The preset is used by
142 TRIMAL to derive the specific thresholds for alignment trimming (minimum gap score,
143 minimum residue similarity score, conserved block size). Since alignment trimming largely
144 depends on the input data and influences the downstream results, TRIMAL can also be run with
145 different settings (e.g. ‘-gappyout’, ‘-strict’, ‘-automated1’; but see Capella-Gutierrez *et al.*
146 (2009). Alternatively, there is also the option to deactivate the alignment trimming with the
147 DISCOMARK option ‘--no-trim’ or use alternative trimming programs such as GBLOCKS
148 (Castresana 2000; Talavera and Castresana 2007) or GUIDANCE2 (Landan and Graur 2008;
149 Sela *et al.* 2015).

150 *4. Blast and alignment to reference.* In this step a genomic reference sequence for each input
151 ortholog is identified and added to the trimmed alignment. This step is particularly important
152 when working with coding sequences which do not contain intron sequences; thus, a genomic
153 sequence is needed to infer intron/exon boundaries. Working with coding sequences is
154 advisable for more distantly related taxa which may include intron length polymorphisms, or
155 to target EPIC markers. Any whole-genome data set (from one of the included taxa or a
156 closely related taxa) can be used as reference for mapping the ortholog sequences. Here,
157 mapping means that the input sequences are compared to the reference sequences, which are
158 defined by the user using the local alignment program BLASTN. The best locally aligning
159 reference sequence (the one that yields the longest alignment among all input sequences) for
160 each orthologous group is added to the corresponding sequence alignment. Reference
161 sequences are cut to 100 base pairs (bp) upstream and downstream of the first, respectively
162 last, BLAST hit to avoid alignment length inflation. Then, the extended alignments are re-
163 aligned with MAFFT. Finally, the best BLAST hits of all sequences belonging to a marker are

164 compared and a ‘`uniq_ref`’ flag is set if they all map to the same reference sequence. The
165 reference alignment step is optional; however, the inclusion of whole-genome data is essential
166 for estimating intron/exon boundaries. Given that information, the focus of target sequences
167 to be amplified can be on entire exon markers, EPIC markers, or a combination.

168 *5. Design primers.* The single-gene alignments, after trimming, mapping and re-aligning to a
169 reference, are used as input to design primer pairs. We integrated the webtool PRiFi
170 (<http://cgi-www.daimi.au.dk/cgi-chili/PriFi/main>, last accessed December 20, 2015) as a
171 Python package that provides a comprehensive set of parameters. As default settings for
172 DISCOMARK we chose the following: estimated product length between 200-1,000 bp
173 (‘`OptimalProductLength = [400, 600, 800, 1000]`’, `MinProductLength = 200`,
174 `MaxProductLength = 1000`’), maximum number of ambiguity positions within the primer
175 sequences (‘`MaxMismatches = 2`’), primer length between 20-30 bp (‘`MinPrimerLength = 20`,
176 `MaxPrimerLength = 30`, `OptimalPrimerLength = [20, 25]`’), melting temperature of the primer
177 pairs between 50-60°C (‘`MinTm = 50.0`, `MinTmWithMismatchesAllowed = 58.0`,
178 `SuggestedMaxTm = 60.0`’), and we set the maximum number of primer pairs per alignment to
179 six (note: only settings different from the PRiFi default are mentioned above). The program
180 PRiFi was originally developed to design intron-spanning markers (but see Fredslund et al.
181 2005). Here we use it because it enables primer design based on MSA input. Parameters for
182 PRiFi can be specified in the DISCOMARK configuration file (‘`discomark.conf`’).

183 *6. Check marker specificity.* To ensure the specificity of the designed primer pairs, we
184 compare their sequences against the NCBI database (‘`refseq_mrna`’). Primer sequences are
185 searched in the NCBI database (‘`refseq_mrna`’) using the online BLASTN interface. The
186 default search settings are restricted to human and bacterial targets using the Entrez query

187 ‘txid2[ORGN] OR txid9606[ORGN]’ because these are most likely to be present as
188 contaminants in sequencing libraries. The result hits of the BLAST search are indicated to the
189 user in the HTML output.

190 *7. Visualize results.* As final step, the program produces a HTML report containing the list of
191 designed primers, an alignment viewer and plots visualizing the discovered set of markers
192 (Fig. 2). Besides the primer sequences the report lists several features such as the melting
193 temperatures, predicted sequence length, and the number of taxa amplified by each primer set
194 (Fig. 2a). Selected primer pairs and primer lists can be downloaded as FASTA or CSV files,
195 respectively. The report highlights the species coverage achieved by each discovered marker,
196 i.e. how many species’ sequences each primer set is expected to amplify, as an estimate of
197 how universally each primer set can be applied. An identification of uniqueness within the
198 reference genome (as an estimator of single-copy status) is given within the flag ‘uref’,
199 starting whether all sequences belonging to a marker had their best BLAST hit to the same
200 reference sequence. Additionally, functional annotations are reported, if available, to guide
201 the user in the selection of markers of interest. Annotations can be supplied in form of a tab-
202 delimited file with the ‘-a’ option. In principle, any kind of annotations can be used depending
203 on the desired research objective. In our usage scenarios, we used gene ontology (GO) terms
204 which were retrieved by mapping the gene IDs contained in the HAMSTR core ortholog set
205 via the UniProt website (<http://www.uniprot.org/>, last accessed December 20, 2015).
206 Common input ortholog sequences are visualized (Fig. 2b). In order to provide a measure of
207 the suitability of the markers for phylogenetic reconstruction the program calculates the
208 number of SNPs between a primer pair by comparing the aligned input sequences against
209 each other. The number of SNPs between each primer pair is visualized in relation to the
210 estimated product length (Fig. 2c) and reported in the tabular output.

211 *Usage cases*

212 *Closely related species - Cloeon dipterum s.l. species complex.* To test the suitability of
213 DISCOMARK for closely related species, we designed primer pairs for the species complex of
214 *C. dipterum* s.l. (Ephemeroptera: Baetidae). The species complex consists of several closely
215 related species, including *Cloeon peregrinator* GATTOLLIAT & SARTORI, 2008 from Madeira
216 (Gattolliat *et al.* 2008; Rutschmann *et al.* 2014). As input to design the primer pairs, we used
217 whole-genome sequencing data of *C. dipterum* L. 1761 and expressed sequence tags (EST) of
218 *Baetis* sp. (Table 1). The sequence reads of *C. dipterum* were trimmed and *de novo* assembled
219 using NEWBLER v.2.5.3 (454 Life Science Corporation) under the default settings for large
220 datasets. Ortholog sequences prediction of both data sets was performed with HAMSTR v.9
221 using the insecta_hmmer3-2 core reference taxa set ([http://www.deep-](http://www.deep-phylogeny.org/hamstr/download/datasets/hmmer3/insecta_hmmer3-2.tar.gz)
222 [phylogeny.org/hamstr/download/datasets/hmmer3/insecta_hmmer3-2.tar.gz](http://www.deep-phylogeny.org/hamstr/download/datasets/hmmer3/insecta_hmmer3-2.tar.gz), last accessed
223 December 20, 2015), including 1,579 orthologous genes. We ran the program DISCOMARK
224 with default settings ('python run_project.py -i input/Cloeon -i input/Baetis -r
225 input/reference/Cloeon.fa -a input/co2go.ixosc.csv -d output/cloeon_baetis'), using the
226 predicted orthologs from HAMSTR and the whole-genome *Cloeon*-data as reference (step 4).
227 For comparison, we also ran DISCOMARK without a reference and also present these results.
228 The Pearson correlation between the number of SNPs located between primer pairs and
229 corresponding estimated product length was calculated using the function cor within the stats
230 package for R (R Development Core Team, 2016). A t-test for significance was performed
231 using the function cor.test.

232 From the total of designed primer pairs (78 markers, 445 primer pairs, see results) we
233 selected eight and amplified them for four species of the *C. dipterum* species complex (Table

234 1) in the laboratory. The eight markers were manually selected based on the following
235 criteria: best alignment (i.e. EPIC markers), longest product length, and most species covered.
236 We used standardized polymerase chain reactions (PCR; 35-40 PCR cycles with annealing
237 temperature of 55°C), followed by Sanger sequencing. Forward and reverse sequences were
238 assembled and edited with GENEIOUS R7 v.7.1.3 (Biomatters Ltd.), indicating ambiguous
239 positions following the IUPAC nucleotide codes. Sequences containing heterozygous indels
240 (i.e. alleles with length polymorphisms) were phased with CODONCODEALIGNER v.3.5.6
241 (CodonCode Corporation). For this we used the implemented ‘Split Heterozygous Indels’
242 function. Multiple sequence alignments were created for all sequences for each marker. The
243 predicted orthologous sequences of *Baetis* sp. were used as reference to infer the exon-intron
244 splicing boundaries (canonical and non-canonical splice site pairs). The final sequence
245 alignments were checked for the occurrence of stop codons and indels, and split into exon and
246 intron parts using a custom Python script (https://github.com/srutschmann/python_scripts, last
247 accessed March 28, 2016). Sequence alignments were phased using the program PHASE
248 v.2.1.1 (Stephens *et al.* 2001; Stephens and Donnelly 2003) with a cutoff value of 0.6
249 (Harrigan *et al.* 2008; Garrick *et al.* 2010), whereby input and output files were formatted
250 using the Perl scripts included in SEQPHASE (Flot 2010). Heterozygous sites that could not
251 be resolved were coded as ambiguity codes for subsequent analyses. After phasing, all
252 alignments were re-aligned with MAFFT. The number of variable and informative sites, and
253 the nucleotide diversity per exon alignment was calculated with a custom script.

254 To investigate the heterogeneity of each marker’s DNA sequences, we reconstructed
255 haplotype networks, using FITCHI (Matschiner 2016). As input for each marker we inferred a
256 gene tree using the program RAXML v.8 (Stamatakis 2014) with the GTRCAT model and
257 1,000 bootstrap replicates under the rapid bootstrap algorithm. The phylogenetic relationships

258 were calculated with Bayesian inference, using MRBAYES v.3.2.3 (Ronquist *et al.* 2012) based
259 on a concatenated nDNA matrix that consisted of the exon sequences from all 15 nDNA
260 markers. The best-fitting model of molecular evolution for each sequence alignment was
261 selected via a BIC criterion in JMODELTEST v.2.1 (Guindon and Gascuel 2003; Darriba *et al.*
262 2012). We calculated 10^6 generations with random seed, a burn-in of 25% and four MCMC
263 chains. As an outgroup we used the predicted orthologous sequences of *Baetis* sp..

264 *Distantly related species - insect order Ephemeroptera.* In this test case, we used contigs
265 derived from whole-genome sequencing projects of the species *Baetis* sp., *Ephemera danica*
266 MÜLLER 1764, *Eurylophella* sp., and *Isonychia bicolor* WALKER 1853 (Table 1). The contigs
267 from each species were used for ortholog predicting with HAMSTR v.13.2.4
268 (<http://sourceforge.net/projects/hamstr/files/hamstr.v13.2.4.tar.gz>, last accessed December 20,
269 2015). We ran DISCOMARK with the default settings twice. For the first run, we used the
270 *Baetis* sp. data as reference ('python run_project.py -i input/Baetis -i input/Ephemera -i
271 input/Eurylophella -i input/Isonychia -r input/reference/Baetis.fa -a input/co2go.ixosc.csv -d
272 output/mayflies'). The second run was performed without a reference ('python run_project.py
273 -i input/Baetis -i input/Ephemera -i input/Eurylophella -i input/Isonychia -a
274 input/co2go.ixosc.csv -d output/mayflies_without_reference').

275 **Results**

276 *Closely related species - species complex of Cloeon dipterum s.l.*

277 Using a reference, DISCOMARK identified 78 nDNA markers with 445 primer pairs for
278 orthologous sequences of both species (*Baetis* sp. and *C. dipterum* s.l.). Ortholog prediction
279 yielded 403 orthologous sequences for the *Baetis* sp. EST-data and 1,211 for *C. dipterum*. For

280 the individual species, DISCOMARK identified 793 markers for *C. dipterum* and 123 for *Baetis*
281 sp. Markers including both species were between 200 and 931 bp with median length of 412
282 bp long. Their number of SNPs per marker ranged from zero to 82 (median: five) with an
283 average of one SNP per 68 bp. Marker length and number of SNPs of the common markers
284 were correlated with a Pearson's correlation coefficient of 0.28 (Pearson's product-moment
285 correlation $P < 0.001$). Without using a reference, DISCOMARK identified 73 markers with
286 460 primer pairs for orthologous sequences of both species. The total run time for this data set
287 on a local Linux machine (quad-core Intel i5, 8 GB RAM) was < 30 min.

288 The haplotype networks based on the eight selected markers showed a clear structure for
289 all markers, including two markers with shared haplotypes for the two species from the U.S.
290 and Madeira (Fig. 3 and Fig. S1, Supporting information). The length of the concatenated
291 sequence alignment of the eight markers was 3,530 bp (2,526 bp exon sequence, Table S1,
292 Supporting information). The exon sequence matrix contained 78 variable sites, 27
293 informative sites, and was 92.6% complete. The nucleotide diversity ranged between 0.009
294 and 0.028 (median: 0.013). Phylogenetic tree reconstruction based on these eight markers
295 resulted in a phylogeny with fully resolved nodes (Bayesian posterior probability (PP) $\geq 95\%$;
296 Fig. 3a).

297 The species *C. dipterum* sp1 was found as outgroup to a clade containing the species *C.*
298 *dipterum* sp2 from Switzerland and the two species from the U.S and Madeira. The latter two
299 species formed a monophyletic clade. The use of the marker set for *C. dipterum* developed
300 here resulted in a fully resolved phylogenetic tree in contrast to the mitochondrial tree of
301 Rutschmann *et al.* (2014). The phylogeny of the *Cloeon*-species complex presented here also

302 is in complete agreement with species tree reconstructions based on 59 nuclear DNA markers
303 (Rutschmann *et al.*, submitted).

304 *Distantly related species - insect order Ephemeroptera*

305 In total, we found 23 orthologs with a total of 53 primer pairs for all four species (Table S2,
306 Supporting information) for the first run with a reference. The input files per species (i.e.
307 putative orthologous sequences) ranged from 1,445 to 1,523. We detected 38 markers that
308 covered three of the species (99 primer pairs), 81 markers covering two species (258 primer
309 pairs), and 118 markers that covered any single species (684 primer pairs). For the individual
310 species, *Baetis* sp. had the most markers available (209) of the single- and multi-species
311 markers. There were 136 markers for *Eurylophella* sp., 104 markers for *I. bicolor*, and 87
312 markers for *E. danica*. The lengths for all markers covering all four species varied between
313 207 and 997 bp with median of 517 bp, containing between 39 and 298 SNPs per marker with
314 a SNP every four bp on average. Marker length and number of SNPs were correlated with a
315 Pearson's correlation coefficient of 0.96 (Pearson's product-moment correlation $P < 0.001$).
316 Without a reference, DISCOMARK identified 25 orthologs with 66 primer pairs for all four
317 species. Run time for this data set on a Linux client (quad-core Intel i5, 8 GB RAM) was < 50
318 min.

319 **Discussion**

320 DISCOMARK is the first stand-alone program of which we are aware that discovers putative
321 single-copy nDNA markers and designs primer pairs based on multiple sequence alignments
322 on a genome-wide scale. The visual output gives guidance on the suitability of each marker
323 i.e. variability within and between species measured as number of SNPs, and information

324 about the included species of each marker. Using this approach, primers can be specifically
325 chosen to match the ‘phylogenetic resolution’, i.e. many markers with intermediate number of
326 SNPs for closely related species, and fewer markers with generally higher number of SNPs
327 for distantly related species can be selected. The automatic processing, including combining,
328 aligning, trimming and blasting sequences of any nucleotide FASTA sequences together with
329 the produced graphical output significantly facilitate the design of primer pairs for a large
330 number of nDNA markers. Nevertheless, users retain a high degree of flexibility by the
331 stepwise nature of the workflow. DISCOMARK is free, open-source software to assist the
332 development of markers for non-model species on the genome scale. We demonstrated the
333 efficacy of our approach for closely related species as well as for members of divergent
334 families within an order of insects. Using a reference genome enabled resolution of intron-
335 exon boundaries but is not a strict requirement for marker design. We strongly recommend
336 carefully checking the selected primer pairs in the alignment viewer. The performance of
337 DISCOMARK will largely depend on the properties of your input data (i.e. fidelity of ortholog
338 prediction, genome complexity, divergence of species.)

339 *Marker development within the order Ephemeroptera*

340 The usage of DISCOMARK added an extensive set of new potential nDNA markers to the ones
341 that have been used to date for mayfly (Ephemeroptera) phylogenies based on few individual
342 genes (histone 3, elongation factor 1 alpha, phosphoenolpyruvate carboxykinase (Vuataz *et al.*
343 2011; Pereira-da-Conceicao *et al.* 2012; Vuataz *et al.* 2013)). Most recent tree reconstructions
344 remain based on mitochondrial DNA markers (e.g. Rutschmann *et al.* 2014 (used three
345 mitochondrial genes); Leys *et al.* 2016 (used cytochrome *c* oxidase subunit 1 (*cox1*) gene)).
346 With DISCOMARK, the availability of more genome data will increase the number of markers

347 suitable for phylogenetic studies. This will promote more fine-scale phylogenetic studies,
348 which are needed to resolve more recent evolutionary events and the phylogenetic
349 relationships of morphologically cryptic species that can not be resolved with standard
350 markers (Dijkstra *et al.* 2014).

351 **Acknowledgements**

352 We thank Katrin Preuß and Susan Mbedi for their help with genome sequencing, and to our
353 research groups, in particular to David Posada and Sara Rocha, and to Eric Coissac and three
354 anonymous reviewers for constructive comments that improved the quality of this project.
355 Research was partially supported by the Leibniz Association (PAKT für Forschung und
356 Innovation “FREDIE” project), the Swiss National Science Foundation (Early
357 PostDoc.Mobility grant P2SKP3_15869 to S.R.), and a visiting fellowship from the Japan
358 Association for the Advancement of Science (L-15543 to M.T.M.). This is publication
359 number 39 of the Berlin Center for Genomics in Biodiversity Research.

485 **Data Accessibility**

486 The program, user manual and example data sets are freely available at:
487 <https://github.com/hdetering/discomark> (last accessed March 28, 2016). Scripts used for the
488 analyses are available at: https://github.com/srutschmann/python_scripts (last accessed March
489 28, 2016). All DNA sequences from this study are available under GenBank accessions:
490 KU987258-KU987260, KU987265-KU987268, KU987273-KU987276, KU987285-
491 KU987288. GenBank accession numbers for sequences included in previous studies are the
492 following: KU971838-KU971840, KU971851, KU972090-KU972092, KU972104,
493 KU972490-KU972492, KU972503, KU973060-KU973061, KU973074. Sequence
494 alignments and tree files are available at the Dryad repository (doi.org/10.5061/dryad.9sf96).

495 **Author Contributions**

496 S.R., H.D., and M.T.M. conceived the study. S.R. coordinated the project and performed the
497 empirical work. S.R. and H.D. designed the program. H.D. implemented the program. S.R.,
498 H.D., and M.T.M wrote the manuscript. S.S. gave guidance for the ortholog prediction. J.F.
499 provided the code of the PRiFi web tool. All authors provided comments and approved the
500 final manuscript.
501

502 **Tables**

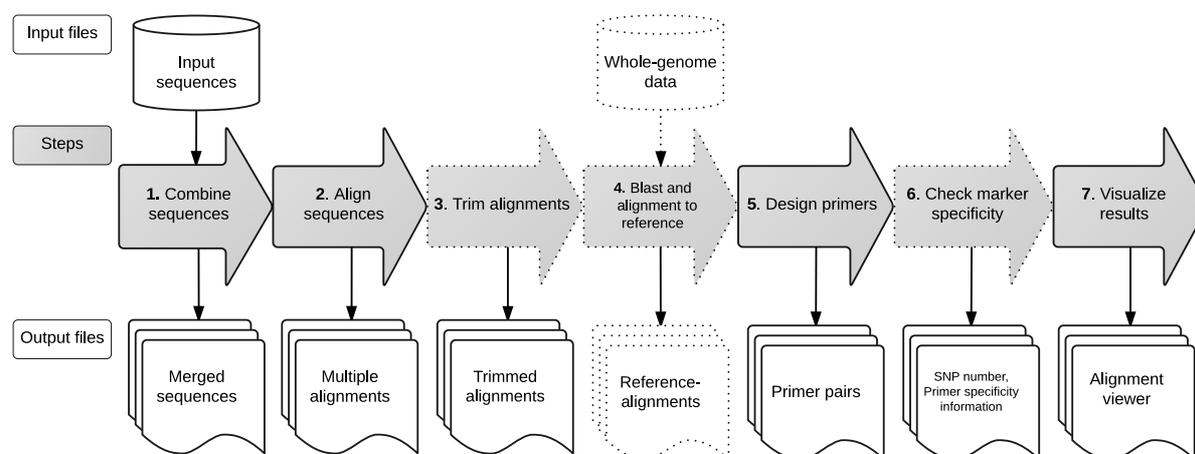

503 **Table 1** List of species used for the usage examples of the closely related species (*Cloeon*
 504 *diptherum* s.l. species complex), and the distantly related species (insect order Ephemeroptera).
 505 Voucher number, geographic origin, and GenBank accession numbers of cytochrome *c*
 506 oxidase subunit 1 (*cox1*) gene are given for the specimens used for the marker amplification.
 507 GenBank accession numbers of the genome data and the number of putative orthologs are
 508 given for the species used to run DISCOMARK. For both data sets species used as reference are
 509 indicated with *.
