Abstract

Gq is a heterotrimeric G protein that is widely expressed in neurons and regulates neuronal activity. To identify pathways regulating neuronal Gq signaling we performed a forward genetic screen in *Caenorhabditis elegans* for suppressors of activated Gq. One of the suppressors is an allele of *sek-1*, which encodes a mitogen-activated protein kinase kinase (MAPKK) in the p38 MAPK pathway. Here we show that *sek-1* mutants have a slow locomotion rate and that *sek-1* acts in acetylcholine neurons to regulate both locomotion and Gq signaling. Furthermore, we find that *sek-1* acts in mature neurons to regulate locomotion. Using genetic and behavioral approaches we demonstrate that other components of the p38 MAPK pathway also play a positive role in regulating locomotion and Gq signaling. Finally, we find that mutants in the *sek-1* p38 MAPK pathway partially suppress an activated mutant of the sodium leak channel NCA-1/NALCN, a downstream target of Gq signaling. Our results suggest that the *sek-1* p38 pathway may modulate the output of Gq signaling through NCA-1.

Introduction

Gq is a widely expressed heterotrimeric G protein that regulates a variety of biological processes ranging from neurotransmission to cardiovascular pathophysiology (Sánchez-Fernández et al., 2014). In the canonical Gq pathway, Gq activates phospholipase Cβ (PLCβ), which cleaves phosphatidylinositol 4,5-bisphosphate (PIP_2) into the second messengers diacylglycerol (DAG) and inositol trisphosphate (IP_3) (Rhee, 2001). In addition to PLCβ, other Gq effectors have been identified including kinases, such as protein kinase Cζ (PKCζ) and Bruton's tyrosine kinase (Btk) (Bence et al., 1997; García-Hoz et al., 2010), and guanine nucleotide exchange factors (GEFs) for the small GTPase Rho, such as Trio (Williams et al., 2007; Vaqué et al., 2013). These noncanonical effectors bridge the activation of Gq to other cellular signaling cascades.

In order to study noncanonical pathways downstream of Gq, we used the nematode *C. elegans* which has a single Gαq homolog (EGL-30) and conservation of the other components of the Gq signaling pathway (Koelle, 2016). In neurons, EGL-30 signals through EGL-8 (PLCβ) (Lackner et al., 1999) and UNC-73 (ortholog of Trio RhoGEF) (Williams et al., 2007). UNC-73 activates RHO-1 (ortholog of RhoA), which has been shown to enhance neurotransmitter release through both diacylglycerol kinase (DGK-1)-dependent and DGK-1-independent pathways (McMullan et al., 2006).

To identify additional signaling pathways that modulate Gq signaling, we screened for suppressors of the activated Gq mutant *egl-30(tg26)* (Doi and Iwasaki, 2002), hereafter referred to as *egl-30(gf). egl-30(gf)* mutant animals exhibit hyperactive locomotion and a "loopy" posture in which worms have exaggerated, deep body bends and loop onto themselves (Bastiani et al., 2003). Here we identify one of the

62 suppressors as a deletion allele in the gene *sek-1*. SEK-1 is a mitogen-activated protein
63 kinase kinase (MAPKK), the *C. elegans* ortholog of mammalian MKK3/6 in the p38
64 MAPK pathway (Tanaka-Hino et al., 2002). The p38 MAPK pathway has been best
65 characterized as a pathway activated by a variety of cellular stresses and inflammatory
66 cytokines (Kyriakis and Avruch, 2012). However, the p38 MAPK pathway has also been
67 shown to be activated downstream of a G protein-coupled receptor in rat neurons
68 (Huang et al., 2004). Btk, a member of the Tec family of tyrosine kinases, has been
69 shown to act downstream of Gq to activate the p38 MAPK pathway (Bence et al., 1997),
70 but *C. elegans* lacks Btk and other Tec family members (Plowman et al., 1999).
71 SEK-1 is activated by the MAPKKK NSY-1 (ortholog of ASK1) and activates the p38
72 MAPKs PMK-1 and PMK-2 (Andrusiak and Jin, 2016). The p38 MAPK pathway
73 consisting of NSY-1/SEK-1/PMK-1 is required for innate immunity in *C. elegans* (Kim et
74 al., 2002). NSY-1 and SEK-1 are also required for the specification of the asymmetric
75 AWC olfactory neurons (Sagasti et al., 2001; Tanaka-Hino et al., 2002); the p38
76 orthologs PMK-1 and PMK-2 function redundantly in AWC specification (Pagano et al.,
77 2015). For both innate immunity and AWC specification, the p38 MAPK pathway acts
78 downstream of the adaptor protein TIR-1 (an ortholog of SARM) (Couillault et al., 2004;
79 Chuang and Bargmann, 2005). Here we show that the TIR-1/NSY-1/SEK-1/PMK-1
80 PMK-2 signaling module also acts to regulate locomotion downstream of Gq signaling.
81

82 **Materials and Methods**

83 ***C. elegans strains and maintenance***

All strains were cultured using standard methods and maintained at 20°C (Brenner, 1974). The *sek-1(yak42)* mutant was isolated from an ENU mutagenesis suppressor screen of the activated Gq mutant *egl-30(tg26)* ("*egl-30(gf)*") (Ailion et al., 2014). *sek-1(yak42)* was outcrossed away from *egl-30(gf)* before further analysis. Double mutant strains were constructed using standard methods (Fay, 2006) often with linked fluorescent markers (Frokjaer-Jensen et al., 2014) to balance mutations with subtle visible phenotypes. Table S1 contains all the strains used in this study.

Mapping

yak42 was mapped using the slow locomotion phenotype and its *egl-30(gf)* suppression phenotype. *yak42* was initially mapped to Chromosome X using strains EG1000 and EG1020, which carry visible marker mutations. These experiments showed that *yak42* was linked to *lon-2*, but at least several map units away. *yak42* was further mapped to about one map unit (m.u.) away from the red fluorescent insertion marker *oxTi668* which is located at +0.19 m.u. on Chromosome X.

Whole-genome sequencing

Strain XZ1233 *egl-30(tg26); yak42* was used for whole-genome sequencing to identify candidate *yak42* mutations. XZ1233 was constructed by crossing a 2X outcrossed *yak42* strain back to *egl-30(tg26)*. Thus, in XZ1233, *yak42* has been outcrossed 3X from its original isolate. DNA was isolated from XZ1233 and purified according to the Hobert Lab protocol (http://hobertlab.org/whole-genome-sequencing/). Ion Torrent sequencing was performed at the University of Utah DNA Sequencing Core

Facility. The resulting data contained 10,063,209 reads of a mean read length of 144 bases, resulting in about 14X average coverage of the *C. elegans* genome. The sequencing data were uploaded to the CloudMap pipeline on the Galaxy platform (Minevich et al., 2012) and SNPs and indels were identified. We filtered out polymorphisms found in other strains we sequenced, leaving us with 605 homozygous mutations. Chromosome X contained 94 mutations: 55 SNPs and 39 indels. Of these, four SNPs were non-synonymous mutations in protein-coding genes, but only 2 were within 5 m.u. of *oxTi668.* However, we were unable to identify *yak42* from the candidate polymorphisms located near *oxTi668*. Transgenic expression of the most promising candidate *pcyt-1* (located at -1.49 m.u.) did not rescue *yak42*. Instead, to identify possible deletions, we scrolled through 2 MB of aligned reads on the UCSC Genome Browser starting at -4.38 m.u. and working towards the middle of the chromosome (0 m.u.), looking for regions that lacked sequence coverage. We found a 3713 bp deletion that was subsequently confirmed to be the *yak42* causal mutation, affecting the gene *sek-1* located at -1.14 m.u.

Locomotion assays

Locomotion assay plates were made by seeding 10 cm nematode growth medium plates with 150 µl of an OP50 (a strain of *E. coli*) stock culture, spread with sterile glass beads to cover the entire plate. Bacterial lawns were grown at room temperature (22.5°C -24.5°C) for 24 hrs and then stored at 4°C until needed. All locomotion assays were performed on first day adults. L4 stage larvae were picked the day before the assay and the experimenter was blind to the genotypes of the strains

assayed. For experiments on strains carrying extrachromosomal arrays, the *sek-1(km4)* control worms were animals that had lost the array from the same plate.

Body bends assays were performed as described (Miller et al., 1999). The locomotion assay plate was brought to room temperature (22.5°C -24.5°C). All strains in an experiment were assayed on the same assay plate. A single animal was picked onto the plate, the plate lid was returned, and the animal recovered for 30 s. Body bends were then counted for one minute. A body bend was counted each time the worm's tail reached the minimum or maximum amplitude of the sine wave. For experiments with *egl-8*, *unc-73*, and *rund-1*, worms were allowed a minimal recovery period (until the worms started moving forward, 5 sec maximum) prior to counting body bends.

For the heat shock experiment, plates of first-day adults were parafilmed and heatshocked in a 34°C water bath for 1 hr. Plates were then un-parafilmed and incubated at 20°C for five hours before performing body bend assays.

Radial locomotion assays were performed by first bringing the locomotion assay plates to room temperature. Animals were picked to the middle of the plate, the plate taped shut, and an x was marked on the lid above where the animals were placed. Assay plates were then incubated at 20°C for 20 hr and the distances of the worms from the starting point were measured.

Quantitative analysis of the waveform of worm tracks was performed by first bringing the locomotion assay plate to room temperature. One strain at a time, five animals were placed on the plate and allowed to roam for 2-5 min. We then took five pictures of each animal's tracks following forward locomotion. Track pictures were taken at 40X on a Nikon SMZ18 microscope with the DS-L3 camera control system. This

process was repeated for all strains per experiment set. Worm track pictures were processed using ImageJ. Tracks were straightened with the segmented line tool and pictures converted to grayscale. Period and 2X amplitude were measured freehand using the line tool. For each worm, five period/amplitude ratios were calculated from each of the five straightened tracks. The ratios were averaged for each worm and these averages were averaged for each strain.

C. elegans pictures

Pictures of worms were taken at 60X on a Nikon SMZ18 microscope with the DS-L3 camera control system. The worms were age-matched as first day adults and each experiment set was photographed on the same locomotion assay plate (assay plate preparation described above). The images were processed using ImageJ and were rotated, cropped, and converted to grayscale.

Molecular biology

Plasmids were constructed using the Gateway cloning system (Invitrogen). Plasmids and primers used are found in Table S2. The *sek-1* cDNA was amplified by RT-PCR from worm RNA and cloned into a Gateway entry vector. To check for proper expression of *sek-1*, an operon GFP was included in expression constructs with the following template: (promoter)p::*sek-1*(cDNA)::*tbb-2utr::gpd-2 operon::GFP::H2B:cye-1utr* (Frøkjær-Jensen et al., 2012). This resulted in untagged SEK-1, but expression could be monitored by GFP expression.

176 ***Injections***

177 *C. elegans* strains with extrachromosomal arrays were generated by standard
178 methods (Mello et al., 1991). Injection mixes were made with a final total concentration
179 of 100 ng/µL DNA. Constructs were injected at 5 ng/µL, injection markers at 5 ng/µL,
180 and the carrier DNA Litmus 38i at 90 ng/µL. Multiple lines of animals carrying
181 extrachromosomal arrays were isolated and had similar behaviors as observed by eye.
182 The line with the highest transmittance of the array was assayed.

183

184 ***Statistical analysis***

185 At the beginning of the project, a power study was conducted on pilot body bend
186 assays using wild type and *sek-1(yak42)* worms. To achieve a power of 0.95, it was
187 calculated that 17 animals should be assayed per experiment. Data were analyzed to
188 check if normally distributed (using the D'Agostino-Pearson and Shapiro-Wilk normality
189 tests) and then subjected to the appropriate analysis using GraphPad Prism 5. For data
190 sets with three or more groups, if the data were normal they were analyzed with a one-
191 way ANOVA; if not, with a Kruskal-Wallis test. Post-hoc tests were used to compare
192 appropriate data sets within an experiment. Reported p-values are corrected. Table S3
193 contains the statistical tests for each experiment. $p<0.05$ = *; $p<0.01$ = **; $p<0.001$ = ***.

194

195 ***Reagent and Data Availability***

196 Strains and plasmids are shown in Table S1 and Table S2 and are available from
197 the *Caenorhabditis* Genetics Center (CGC) or upon request. The authors state that all

198 data necessary for confirming the conclusions presented in the article are represented
199 fully within the article and Supplemental Material.
200
201 **Results**
202 ***sek-1* suppresses activated Gq**
203 To identify downstream effectors of Gαq, we performed a forward genetic screen
204 for suppressors of the activated Gq mutant, *egl-30(tg26)* (Doi and Iwasaki, 2002),
205 referred to here as *egl-30(gf). egl-30(gf)* worms are small, hyperactive, and have a
206 "loopy" posture characterized by a high-amplitude waveform (Figure 1B). Thus, we
207 screened for worms that are larger, less hyperactive, and less loopy. We isolated a
208 recessive suppressor, *yak42*, and mapped it to the middle of Chromosome X (see
209 Materials and Methods). Whole-genome sequencing revealed that *yak42* carries a large
210 deletion of the *sek-1* gene from upstream of the start codon to exon 4 (Figure 1A).
211 *yak42* also failed to complement *sek-1(km4)*, a previously published *sek-1* deletion
212 allele (Figure 1A) (Tanaka-Hino et al., 2002).
213 *egl-30(gf)* double mutants with either *sek-1(yak42)* or *sek-1(km4)* are bigger than
214 *egl-30(gf)* worms (Figure 1B), not hyperactive (Figure 1C). and have a tendency to kink
215 when moving backward. Additionally, both *sek-1* mutations suppress the loopy
216 waveform phenotype (Figure S1A, B).
217 *sek-1(yak42)* was outcrossed from *egl-30(gf)* and assayed for locomotion
218 defects. Both the *sek-1(yak42)* and *sek-1(km4)* mutants are coordinated but move more
219 slowly than wild-type (Figure 1D). *sek-1(ag1)*, a point mutation in exon 5 (Kim et al.,
220 2002), also causes a similar slow locomotion phenotype (Figure S1C). To test whether

the *egl-30(gf)* suppression phenotype might be an indirect effect of the slow locomotion of a *sek-1* mutant, we built an *egl-30(gf)* double mutant with a mutation in *unc-82*, a gene required for normal muscle structure. *unc-82* mutants are coordinated but move slowly, similar to a *sek-1* mutant (Hoppe et al., 2010). However, although an *egl-30(gf) unc-82(e1220)* double mutant moves more slowly than *egl-30(gf)*, it is still small and loopy (Figure 1B). Thus, *sek-1* appears to be a specific suppressor of multiple phenotypes of the *egl-30(gf)* mutant, suggesting that *sek-1* regulates locomotion and acts downstream of Gq.

EGL-30/Gαq is negatively regulated by GOA-1, the worm Gαo/i ortholog (Hajdu-Cronin et al., 1999). We tested whether *sek-1* also suppresses a *goa-1* loss-of-function mutant that causes a hyperactive phenotype similar to *egl-30(gf).* Indeed, *sek-1(km4)* suppresses *goa-1(sa734)* (Figure S1D). One downstream effector of GOA-1 is the DAG kinase DGK-1 (DGKΘ ortholog) that inhibits DAG-dependent functions such as synaptic vesicle release (Nurrish *et al.* 1999; Miller *et al.* 1999). *dgk-1(sy428)* animals are hyperactive, but *sek-1(km4)* does not suppress *dgk-1*. Rather, the *sek-1 dgk-1* double mutant is uncoordinated and looks like neither *sek-1* nor *dgk-1* mutants, confounding the interpretation of how *sek-1* genetically interacts with *dgk-1*.

sek-1 acts in mature acetylcholine neurons

egl-30 is widely expressed and acts in neurons to regulate locomotion (Lackner et al., 1999), so it is possible that *sek-1* also acts in neurons to regulate Gq signaling. *sek-1* is expressed in neurons, intestine, and several other tissues (Tanaka-Hino et al.,

2002) and has been shown to function in GABA neurons to possibly promote GABA release (Vashlishan et al., 2008).

To identify the cell type responsible for the *sek-1* locomotion phenotypes, we expressed the wild-type *sek-1* cDNA under different cell-specific promoters and tested for transgenic rescue of a *sek-1* null mutant. Expression of *sek-1* in all neurons (using the *unc-119* promoter) or in acetylcholine neurons (using *unc-17p*) was sufficient to rescue the *sek-1* mutant slow locomotion phenotype, but expression in GABA neurons (using *unc-47p*) was not sufficient to rescue (Figure 2A, B). These results indicate that *sek-1* acts in acetylcholine neurons to regulate locomotion.

We next tested whether *sek-1* also acts in neurons to suppress *egl-30(gf)*. Expression of *sek-1* under pan-neuronal and acetylcholine neuron promoters rescued the *sek-1* suppression of *egl-30(gf)*. Specifically, *egl-30(gf) sek-1* double mutants expressing wild-type *sek-1* in all neurons or acetylcholine neurons had a hyperactive, loopy, small phenotype that resembled the *egl-30(gf)* single mutant (Figure 2C, D). However, expression of *sek-1* in GABA neurons did not rescue the suppression phenotype (Figure 2C, D). Together, these data show that *sek-1* acts in acetylcholine and not GABA neurons to regulate both wild-type locomotion and to modulate Gq signaling.

Because *sek-1* acts in the development of the AWC asymmetric neurons, we asked whether *sek-1* also has a developmental role in regulating locomotion by testing whether adult-specific *sek-1* expression (driven by a heat-shock promoter) is sufficient to rescue the *sek-1* mutant. We found that *sek-1* expression in adults rescues the *sek-1* slow locomotion phenotype (Figure 2E). This result indicates that *sek-1* is not required

for development of the locomotion circuit and instead acts in mature neurons to regulate locomotion.

The p38 MAPK pathway is a positive regulator of Gq signaling

SEK-1 is the MAPKK in a p38 MAPK pathway (Tanaka-Hino et al., 2002). This pathway consists of NSY-1 (MAPKKK), SEK-1 (MAPKK), and PMK-1 or PMK-2 (MAPKs)(Andrusiak and Jin, 2016). TIR-1 acts upstream of NSY-1. This p38 MAPK signaling module has been shown to function in innate immunity and the development of the AWC olfactory neurons (Chuang and Bargmann, 2005).

We tested whether the entire p38 MAPK and TIR-1 signaling module also regulates locomotion and suppression of activated Gq. Both *tir-1(tm3036)* and *nsy-1(ok593)* mutant animals have slow locomotion on their own and also suppress the hyperactivity, deep body bends and small size of *egl-30(gf)* (Figure 3A-D; Figure S2A, B). We also tested single mutants in each of the three worm p38 MAPK genes (*pmk-1, pmk-2* and *pmk-3)* and a *pmk-2 pmk-1* double mutant. Although we found that the *pmk-2* and *pmk-3* single mutants were slightly slow on their own, only the *pmk-2 pmk-1* double mutant phenocopied *sek-1* and suppressed both the hyperactivity and deep body bends of *egl-30(gf)* (Figure 3, E-G). Thus, *pmk-2* and *pmk-1* act redundantly downstream of *sek-1* to suppress *egl-30(gf).* These data suggest that the p38 MAPK pathway regulates locomotion in *C. elegans* and acts genetically downstream of *egl-30*.

The JNK MAPK pathway, related to the p38 MAPK family, also regulates locomotion in *C. elegans*. Specifically, the JNK pathway members *jkk-1* (JNK MAPKK) and *jnk-1* (JNK MAPK) have been shown to act in GABA neurons to regulate

289 locomotion (Kawasaki et al., 1999). We found that the *jkk-1* and *jnk-1* single mutants
290 had slow locomotion and that the double mutants with p38 MAPK pathway members
291 exhibited an additive slow locomotion phenotype (Figure S2C). Moreover, neither *jkk-1*
292 nor *jnk-1* suppressed *egl-30(gf)* (data not shown). Thus, the JNK and p38 MAPK
293 pathways regulate locomotion independently and the JNK pathway is not involved in Gq
294 signaling.

295 We also tested the involvement of possible p38 MAPK pathway effectors. One of
296 the targets of PMK-1 is the transcription factor ATF-7 (Shivers et al., 2010). Both the *atf-*
297 *7(qd22 qd130)* loss-of-function mutant and the *atf-7(qd22)* gain-of-function mutant
298 moved slowly compared to wild-type animals (Figure S2D). However, *atf-7(qd22 qd130)*
299 did not suppress *egl-30(gf)* (data not shown), suggesting that *atf-7* is not a target of this
300 pathway or acts redundantly with other downstream p38 MAPK targets. We also tested
301 *gap-2*, the closest *C. elegans* homolog of ASK1-interacting Protein (AIP1) which
302 activates ASK1 (the ortholog of *C. elegans* NSY-1) in mammalian systems (Zhang et
303 al., 2003). A *C. elegans gap-2* mutant has no locomotion defect (Figure S2E). Finally,
304 we tested VHP-1, a phosphatase for p38 and JNK MAPKs that inhibits p38 MAPK
305 signaling (Kim et al., 2004). However, the *vhp-1(sa366)* mutant also has no locomotion
306 defect (Figure S2E).

307 *egl-30(gf)* animals are loopy and hyperactive so we tested whether increased
308 activation of the TIR-1/p38 MAPK signaling module causes similar phenotypes. The *tir-*
309 *1(ky648gf)* allele leads to a gain-of-function phenotype in the AWC neuron specification
310 (Chang et al., 2011), but does not cause a locomotion phenotype reminiscent of *egl-*
311 *30(gf)* (Figure S2F, G).

312

313 **Genetic interactions of *sek-1* with pathways acting downstream of Gq**

314 Our forward genetic screen for suppressors of *egl-30(gf)* identified mutants that
315 fall into three different categories: mutants in the canonical Gq pathway such as the
316 PLC *egl-8* (Lackner et al., 1999), mutants in the RhoGEF Trio pathway such as *unc-73*
317 (Williams et al., 2007), and mutants that affect dense-core vesicle biogenesis and
318 release (Ailion et al., 2014; Topalidou et al., 2016a).

319 To test if *sek-1* acts in these pathways we used genetic epistasis analysis. Loss-
320 of-function alleles of *egl-8(sa47)*, *unc-73(ox317),* and *rund-1(tm3622)* have slow
321 locomotion (Figure 4A-C). Our data show that *sek-1* enhances the phenotype of *egl-8*
322 and *rund-1* single mutants, suggesting that *sek-1* does not act in the same pathway as
323 *egl-8* or *rund-1* (Figure 4A, B). By contrast, *sek-1* does not enhance the slow locomotion
324 phenotype of *unc-73* mutants (Figure 4C), suggesting that *sek-1* may act in the same
325 genetic pathway as the Trio RhoGEF *unc-73.*

326 We next tested whether *sek-1* interacts with *rho-1*, encoding the small G protein
327 activated by Trio. *rho-1* is required for viability so we could not use a loss-of-function
328 allele to test for a genetic interaction (Jantsch-Plunger et al., 2000). Instead we used an
329 integrated transgene overexpressing an activated *rho-1* mutant allele specifically in
330 acetylcholine neurons. Animals carrying this activated RHO-1 transgene, referred to
331 here as *rho-1(gf)*, have a loopy posture reminiscent of *egl-30(gf)* (McMullan et al.,
332 2006), and a decreased locomotion rate. *rho-1(gf) sek-1(km4)* double mutants had a
333 loopy body posture like *rho-1(gf)* and an even slower locomotion rate (Figure 4D, E),
334 suggesting that *sek-1* and *rho-1(gf)* mutants have additive locomotion phenotypes.

However, both *sek-1(km4)* and *sek-1(yak42)* suppress the slow growth rate of the *rho-1(gf)* mutant. Because *sek-1* does not enhance *unc-73* mutants and suppresses some aspects of the *rho-1(gf)* mutant, *sek-1* may modulate output of the Rho pathway, though it probably is not a direct transducer of Rho signaling.

sek-1 and _nsy-1_ partially suppress activated NCA

The data above did not clarify the relationship of *sek-1* to the Rho pathway acting downstream of Gq. The downstream target of this Gq-Rho pathway appears to be the NCA-1 cation channel (Topalidou et al., 2016b). NCA-1 and its orthologs are sodium leak channels associated with rhythmic behaviors in several organisms (Nash et al., 2002; Lu et al., 2007; Shi et al., 2016). In *C. elegans*, NCA-1 potentiates persistent motor circuit activity and sustains locomotion (Gao et al., 2015).

To examine interactions of the *sek-1* p38 MAPK pathway with NCA-1, we tested whether *sek-1* and *nsy-1* mutants suppress the activated NCA-1 mutant *ox352*, referred to as *nca-1(gf)*. The *nca-1(gf)* animals are coiled and uncoordinated; thus, it is difficult to measure their locomotion rate by the body bend assay because they sometimes do not propagate sinusoidal waves down the entire length of their body. Instead, we used a radial locomotion assay in which we placed animals in the center of a 10 cm plate and later measured how far the animals had moved. *nca-1(gf)* double mutants with either *sek-1(km4)* or *nsy-1(ok593)* uncoil a bit but still exhibit uncoordinated locomotion (Figure 5A). In fact, though these double mutants show more movement in the anterior half of their bodies than *nca-1(gf)*, they propagate body waves to their posterior half even more poorly than the *nca-1(gf)* mutant. However, both *sek-1* and *nsy-1* clearly

suppress the small size and slow growth rate of the *nca-1(gf)* mutant (Figure 5A) and in radial locomotion assays, *sek-1* and *nsy-1* weakly suppressed the *nca-1(gf)* locomotion phenotype (Figure 5B). Together these data suggest that mutants in the *sek-1* p38 MAPK pathway partially suppress some aspects of the *nca-1(gf)* mutant.

Given that *sek-1* acts in acetylcholine neurons to regulate wild-type and *egl-30(gf)* locomotion, we tested if the same neuron class is responsible for *sek-1* suppression of *nca-1(gf)*. Expression of *sek-1* in all neurons or in acetylcholine neurons of *nca-1(gf) sek-1(km4)* animals restored the *nca-1(gf)* size and posture phenotypes. These worms are small and coiled and closely resemble the *nca-1(gf)* mutant (Figure 5C). By contrast, expression of *sek-1* in GABA neurons did not affect the size or posture of the *nca-1(gf) sek-1* double mutant (Figure 5C). These data suggest that *sek-1* acts in acetylcholine neurons to regulate *nca-1(gf)* locomotion. However, in radial locomotion assays, expression of *sek-1* in none of these neuron classes significantly altered the movement of the *nca-1(gf) sek-1* double mutant (Figure 5D), though the weak suppression of *nca-1(gf)* by *sek-1* in this assay makes it difficult to interpret these negative results. We make the tentative conclusion that *sek-1* partially suppresses *nca-1(gf)* locomotion and probably acts in the acetylcholine neurons where it also acts to regulate wild-type and *egl-30(gf)* locomotion, suggesting a common neuronal site of action of this pathway.

Discussion

In this study we identified a new neuronal role for the mitogen-activated protein kinase kinase SEK-1 and the p38 MAPK pathway as a positive regulator of locomotion

and Gq signaling. The p38 MAPK pathway has been best characterized as a pathway activated by a variety of cellular stresses and inflammatory cytokines (Kyriakis and Avruch, 2012), but it has also been implicated in neuronal function, including some forms of mammalian synaptic plasticity (Bolshakov *et al.* 2000; Rush *et al.* 2002; Huang *et al.* 2004). In *C. elegans*, Gq plays a positive role in locomotion by promoting acetylcholine release, so we tested whether the slow locomotion of *sek-1* mutants is directly related to the role of *sek-1* as a regulator of Gq signaling. Through rescue experiments, we found that SEK-1 acts in acetylcholine neurons to regulate both the rate of locomotion and Gq signaling. Previously, *sek-1* has been shown to act in GABA neurons to regulate sensitivity to the acetylcholinesterase inhibitor aldicarb (Vashlishan et al., 2008), and to act in interneurons to regulate trafficking of the GLR-1 glutamate receptor and the frequency of worm reversals (Park and Rongo, 2016). Thus, *sek-1* may play distinct roles in different neuron types. Our data indicate a role for *sek-1* as a positive regulator of Gq signaling in acetylcholine neurons.

In addition to SEK-1, we identified other p38 pathway components regulating Gq signaling. Specifically, we found that mutants in *tir-1*, *nsy-1* and a *pmk-1 pmk-2* double mutant exhibit locomotion defects identical to *sek-1* and suppress activated Gq, suggesting that they act in a single p38 pathway to modulate signaling downstream of Gq. These results indicate a redundant function for PMK-1 and PMK-2 in regulating locomotion rate and Gq signaling. PMK-1 and PMK-2 also act redundantly for development of the asymmetric AWC neurons and to regulate induction of serotonin biosynthesis in the ADF neurons in response to pathogenic bacteria (Pagano et al.,

403 2015). By contrast, PMK-1 acts alone in the intestine to regulate innate immunity and in
404 interneurons to regulate GLR-1 trafficking (Pagano et al., 2015; Park and Rongo, 2016).
405 What is the downstream effector of *sek-1* p38 MAPK signaling in this Gq
406 signaling pathway? There are several known downstream effectors of p38 MAPK
407 signaling in *C. elegans*, including the transcription factor ATF-7 (Shivers et al., 2010;
408 Inoue et al., 2005; Xie et al., 2013). Our data indicate that ATF-7 is not required for the
409 p38 MAPK-dependent regulation of Gq signaling. It is possible that this p38 MAPK
410 pathway activates molecules other than transcription factors to regulate Gq signaling. It
411 is also possible that the *sek-1* p38 pathway activates multiple downstream effectors that
412 are not individually required.
413 One of the pathways that transduce signals from Gq includes the RhoGEF
414 Trio/UNC-73, the small GTPase Rho, and the cation channel NALCN/NCA-1 (Williams
415 et al., 2007; Topalidou et al., 2016b). We found that mutations in the *sek-1* p38 MAPK
416 pathway partially suppress an activated NCA-1 mutant and that *sek-1* probably acts to
417 control NCA-1 activity in the same neurons where it acts to regulate locomotion and Gq
418 signaling. Given the precedence for direct phosphorylation of sodium channels by p38
419 to regulate channel properties (Wittmack et al., 2005; Hudmon et al., 2008), it is
420 possible that PMK-1 and PMK-2 phosphorylate NCA-1 to regulate its expression,
421 localization, or activity. Our genetic study sets the foundation for further investigation of
422 the specific role of the *sek-1* p38 pathway in the regulation of Gq signaling and NCA-1
423 channel activity.

Figure Legends

Figure 1: *sek-1* acts downstream of Gαq to regulate locomotion behavior

(a) Gene structure of *sek-1*. White boxes depict the 5' and 3' untranslated regions, black boxes depict exons, and lines show introns. The positions of the *yak42* and *km4* deletions are shown. *yak42* is a 3713 bp deletion that extends to 1926 bp upstream of the start codon. Drawn with Exon-Intron Graphic Maker (http://www.wormweb.org/exonintron). Scale bar is 100 bp.

(b) *sek-1(yak42)* and *sek-1(km4)* suppress the small size and loopy waveform of *egl-30(tg26)*, written here as *egl-30(gf). unc-82(e1220)* does not suppress *egl-30(gf).* Photos of first-day adult worms. WT: wild type.

(c) *egl-30(gf)* is hyperactive compared to wild-type and suppressed by *sek-1(yak42)* and *sek-1(km4)*. ***, $p<0.001$, error bars = SEM, n=20.

448 (d) *sek-1* mutant worms have slow locomotion. ***, p<0.001 compared to wild-type, error
449 bars = SEM, n=20.
450
451 **Figure 2: *sek-1* acts in mature acetylcholine neurons to regulate locomotion**
452 (A) *sek-1* acts in neurons to regulate locomotion. The *sek-1* wild-type cDNA driven by
453 the *unc-119* pan-neuronal promoter *[unc-119p::sek-1(+)]* rescues the slow locomotion
454 phenotype of *sek-1(km4)* worms. ***, p< 0.001, error bars = SEM, n=20.
455 (B) *sek-1* acts in acetylcholine neurons to regulate locomotion. *sek-1* WT cDNA driven
456 by the *unc-17* acetylcholine neuron promoter *[unc-17p::sek-1(+)]* rescues the slow
457 locomotion phenotype of *sek-1(km4)* worms but *sek-1* expression in GABA neurons
458 using the *unc-47* promoter *[unc-47p::sek-1(+)]* does not. p< 0.001, error bars = SEM,
459 n=20.
460 (C-D) *sek-1* acts in acetylcholine neurons to suppress *egl-30(gf).* Worms expressing
461 *unc-119p::sek-1(+)* or *unc-17p::sek-1(+)* do not have the *egl-30(gf) sek-1* phenotype but
462 worms expressing *unc-47p::sek-1(+)* are identical to *egl-30(gf) sek-1* both for waveform
463 (C) and in the locomotion assay (D). Kruskal-Wallis test, ***, p< 0.001, **, p<0.01; error
464 bars = SEM, n=17-20.
465 (E) *sek-1* acts in mature neurons to regulate locomotion. *hsp-16.2p::sek-1(+)* rescues
466 the slow locomotion phenotype of *sek-1(km4)*. ***, p< 0.001, error bars = SEM, n=20.
467
468 **Figure 3: The p38 MAPK pathway regulates locomotion downstream of *egl-30***
469 (A) *tir-1(tm3036)* mutant animals have slow locomotion. ***, p<0.001, error bars = SEM,
470 n=20.

(B) *tir-1(tm3036)* suppresses *egl-30(gf)*. *egl-30(gf) tir-1* animals move more slowly than the hyperactive *egl-30(gf)* animals. ***, p< 0.001, error bars = SEM, n=20.

(C) *nsy-1(ok593)* mutant animals have slow locomotion. ***, p<0.001, error bars = SEM, n=20.

(D) *nsy-1(ok593)* suppresses *egl-30(gf)*. *egl-30(gf) nsy-1* animals move more slowly than the hyperactive *egl-30(gf)* animals. ***, p< 0.001, error bars = SEM, n=20.

(E) *pmk-2, pmk-2 pmk-1,* and *pmk-3* mutant animals have slow locomotion. ***, p< 0.001; *, p<0.05, compared to WT, error bars = SEM, n=20.

(F) A *pmk-2 pmk-1* double mutant suppresses the hyperactivity of *egl-30(gf)*. ***, p< 0.001, error bars = SEM, n=20.

(G) A *pmk-2 pmk-1* double mutant suppresses the deep body bends of *egl-30(gf)*. *egl-30(gf)* animals with mutations in either *pmk-1, pmk-2,* or *pmk-3* are still small and loopy. *egl-30(gf) pmk-2 pmk-1* animals are less loopy and have a more wild-type posture.

Figure 4: *sek-1* acts in the same genetic pathway as *unc-73*

(A) *sek-1* does not act in the same genetic pathway as *egl-8.* The *sek-1(km4)* mutation enhances the slow locomotion of *egl-8(sa47)* mutants. ***, p< 0.001, error bars = SEM, n=20.

(B) *sek-1* does not act in the same genetic pathway as *rund-1*. The *sek-1(km4)* mutation enhances the slow locomotion of *rund-1(tm3622)* mutants. ***, p< 0.001, error bars = SEM, n=20.

(C) *sek-1* may act in the same genetic pathway as *unc-73*. The *sek-1(km4)* mutation does not enhance the slow locomotion phenotype of *unc-73* mutants. ns, p>0.05, error bars = SEM, n=20.

(D) *sek-1(km4)* does not suppress the high-amplitude waveform of *nzIs29 rho-1(gf)* animals. *rho-1(gf)* and *rho-1(gf) sek-1(km4)* animals have similar body posture.

(E) *sek-1(km4)* does not suppress the slow locomotion of *rho-1(gf)* animals. ***, p< 0.001, error bars = SEM, n=20.

Figure 5: *sek-1* and *nsy-1* weakly suppress *nca-1(gf)*

(a) *nca-1(gf)* mutants are small and tightly coiled. The phenotypes of these *nca-1(ox352)* animals are partially suppressed by *nsy-1(ok593)* and *sek-1(km4)*. Photos of first-day adults.

(b) *nsy-1* and *sek-1* suppress *nca-1(gf)* locomotion. *nca-1(gf)* animals travel a small distance from the center of the plate in the radial locomotion assay. *nca-1(gf) nsy-1(ok593)* and *nca-1(gf) sek-1(km4)* worms move further than *nca-1(gf)* worms. **, p<0.01; *, p<0.05. Error bars = SEM, n=30.

(c) Expression of *sek-1* in all neurons and in acetylcholine neurons partially reverts the *sek-1* mutant suppression of *nca-1(gf)* size and body posture. White arrowheads depict food piles created by *nca-1(gf) sek-1(km4)* animals due to their uncoordinated locomotion. Such food piles are not made by *nca-1(gf)* animals.

(d) None of the neuronal *sek-1* rescuing constructs revert the radial locomotion phenotype of *nca-1(gf) sek-1(km4)* animals. Although the pan-neuronal and acetylcholine neuron constructs revert the size phenotype of *nca-1(gf) sek-1(km4)*,

these animals do not move a significantly different distance than *nca-1(gf) sek-1(km4)* animals. ns, p>0.05. Error bars = SEM, n=19-24.

Figure S1: *sek-1* suppresses *egl-30(gf)* deep body bends

(a) *egl-30(gf)* mutants have deeper body bends than wild-type (WT) and *sek-1* mutations suppresses this loopy posture. Images show tracks of forward-moving first-day adults.

(b) Quantification of the waveform phenotype. ***, p<0.001, error bars = SEM, n=4-5.

(c) *sek-1(ag1)* mutant animals have slow locomotion. ***, p<0.001, error bars = SEM, n=10.

(d) *sek-1* suppresses *goa-1* hyperactivity. *goa-1(sa734) sek-1(km4)* animals move more slowly than *goa-1(sa734)* animals. ***, p<0.001, error bars = SEM, n=20.

Figure S2: Locomotion of p38 and JNK MAPK pathway mutants

(A) *tir-1(tm3036)* suppresses *egl-30(gf)*. *egl-30(gf) tir-1(tm3036)* animals are less loopy and have a more wild-type posture.

(B) *nsy-1(ok593)* suppresses *egl-30(gf)*. *egl-30(gf) nsy-1(ok593)* animals are less loopy and have a more wild-type posture.

(C) *jkk-1* and *jnk-1* act in parallel to *sek-1* and *pmk-2 pmk-1*. The *jnk-1(gk7) sek-1(km4)* double mutant and *pmk-2(qd279 qd171) pmk-1(km25) jkk-1(km2)* triple mutants move more slowly than the respective individual mutants. **, p< 0.01, *, p<0.05; error bars = SEM, n=20.

(D) Worms with gain-of-function or loss-of-function alleles of *atf-7* are slower than wild-type worms. p< 0.001, error bars = SEM, n=20.

(E) Worms lacking *gap-2* and *vhp-1* move like wild-type worms. Neither *gap-2(tm478)* nor *vhp-1(sa366)* confers a slow locomotion phenotype. ns, p>0.05 compared to WT, error bars = SEM, n=20.

(F-G) *tir-1(ky648gf)* animals do not have loopy or hyperactive locomotion. *tir-1(ky648gf)* worms have wild-type posture and are slower than wild-type animals. ***, p< 0.001, error bars = SEM, n=20.
