10 **Abstract**

11 Wool is one of the most important animal fibers in the textile industry and the
12 diameter directly affects its economic value. However, the molecular mechanisms
13 underlying the wool diameter have not been fully elucidated. In the present study,
14 high-throughput RNA-Seq technology was employed to explore the skin
15 transcriptome using 3 sheep with fine wool (fiber diameter, FD<21.0μm) and 3 sheep
16 with coarse wool (fiber diameter, FD>27.0μm). In total, 28,607,228 bp clean reads
17 were obtained, and 78.88%±3.84% was uniquely aligned to the reference genome
18 across the six samples. In total, 19,914 mRNA transcripts were expressed (FPKM>0)
19 in the six skin samples, among which there were certain well-known genes affecting
20 the skin hair cycle, such as KRTAP7-1 ,KRT14 ,Wnt10b ,Wnt2b, β-catenin ,and FGF5.
21 Furthermore, 467 expressed genes were significantly differentially expressed between
22 the two groups, including 21 genes up-regulated and 446 genes down-regulated in the

1 sheep with the smaller fiber diameter. To verify the results, 13 differentially expressed
2 genes were randomly selected to validate the expression patterns using qRT-PCR, and
3 the correlation between the mRNA expression level from qRT-PCR and RNA-Seq
4 data was 0.999 ($P < 0.05$). These differentially expressed genes were particularly
5 enriched in GO processes related to lipid metabolism, skin development,
6 differentiation, and immune function ($P < 0.05$). The biological processes were
7 involved in collagen catabolism, negative regulation of macromolecule metabolism,
8 steroid hormone stimulation and lipid metabolism. A significant KEGG pathway
9 involving the “metabolism of lipids and lipoproteins” was also enriched. This study
10 revealed that the lipid metabolism might constitute one of the major factors related to
11 wool diameter.

12

13 **Introduction**

14 Sheep (*Ovis aries*) is a predominant domestic animal providing not only meat
15 and milk but also wool. Wool is a distinguishing feature of sheep compared to other
16 farm animals, and its biology has been the focus of much research. Wool is one of the
17 earliest natural fibers used in the textile industries.. The wool fiber is soft and elastic,
18 and its products possess the advantage of being natural, having strong hygroscopicity,
19 providing warmth and comfort, etc. The key traits contributing to the economic value
20 of wool include fiber diameter, density, strength and length which are determined by
21 both genetics[1,2] and the environment[3]. Understanding the genetic principles of
22 wool traits would be helpful for promoting sheep breeding and also for elucidating the

1 mechanism of hair development in humans.

2 Over the past few decades, progress has been made on the study of wool quality
3 using genetic technologies. In the beginning, these studies mainly focused on the wool
4 biology and the quantitative trait loci associated with wool economic traits, and some
5 major genes have been validated. For example, KRTAP6 and KRTAP8, located in
6 Chromosome 1[4], control wool diameter and agouti is a key locus affecting wool
7 color. The N-type gene, also named “halo-hair 1” (HH1) gene, is another important
8 gene controlling wool quality, as mutations in this gene cause extreme hairiness (or
9 medullation), resulting in the production of fibers that are ideal for carpet wool
10 production[5,6].

11 With rapid development of molecular biological techniques, especially the
12 Next-generation sequencing, large-scale gene expression detection becomes possible.
13 Fan *et al.* [2] examined the skin gene expression profiles associated with coat color in
14 sheep using RNA sequencing (RNA-Seq). Kang *et al.* [3] studied characteristics of
15 curly fleece utilizing transcriptome data. Yue *et al.* [7,8] performed *de novo*
16 transcriptome sequencing of sheep skin and found fiber diameter was related to a few
17 lipoic acid differentially expressed genes and antisense transcripts. However, no other
18 studies have examined global gene expression in relation to wool fiber diameter. To
19 gain better understanding of molecular mechanisms controlling wool fiber diameter,
20 global gene expression profiles in skin of sheep with coarse wool versus fine wool
21 were explored. The results showed that wool fiber diameter is associated with lipid
22 metabolism and provided valuable information for future studies.

1 **Materials and Methods**

2 **Experimental Animals and Sample Collection**

3 The experimental animals are Erdos Fine Wool sheep from Inner Mongolia
4 Autonomous Region, China. Three hundred and sixty unrelated female ewes, that
5 were 3 years old and raised in the same conditions, were randomly selected from a
6 sheep farm. The diameter of wool from each animal was measured and recorded.
7 According to the fineness of the wool, 3 animals of fine wool (fiber diameter,
8 $FD < 21.0\mu\text{m}$, FW) and coarse wool (fiber diameter, $FD > 27.0\mu\text{m}$, CW) were sampled.
9 A piece of skin (approximately 0.5cm^2) on the body side was cut off and frozen
10 immediately in liquid nitrogen and stored at -80°C until subsequent use.

11 The experiment was conducted following the Guidelines on Ethical Treatment
12 Animals (2006 No.398), set by the Ministry of Science and Technology, China. The
13 sampling procedures complied with the Animal Ethics Committee at Inner Mongolia
14 Academy of Agricultural & Animal Husbandry Sciences.

15 **RNA Extraction, cDNA Library Construction and Illumina Sequencing**

16 RNA from the two groups was extracted using Trizol reagent (TaKaRa)
17 according to the manufacturer's instructions, and the purity and degradation were
18 determined on 1% agarose gels. DNA was removed from the RNA extracts by
19 incubation with RNase-free DNase for 30 min at 37°C .

20 Poly(A) mRNA was isolated from total RNA using oligo(dT) magnetic beads
21 (Illumina). Fragmentation buffer was added to disrupt the purified mRNA into short
22 fragments. Using these short fragments as templates, first-strand cDNA synthesis was

1 performed using random hexamer primers and reverse transcriptase (Illumina).
2 Second-strand cDNA was synthesized using RNase H (Illumina), DNA polymerase I
3 (Illumina), dNTPs and buffer. These cDNA fragments were subjected to end repair
4 process and ligation of adapters. These products were purified and enriched with PCR
5 to create the finally cDNA library. The library preparations were sequenced on an
6 Hiseq 2000 platform and 100 bp paired-end reads were generated.

7 **Sequence preprocessing and functional annotation**

8 In order to obtain clean data, all sequenced raw data were processed including
9 removing the adapter, filtering the low quality reads and the proportion of N more
10 than 10% using an in-house Perl script. Then, all filtered data were mapped to the
11 sheep genome (V 3.1) using Tophat2, with no discordant and mixed. Unique mapped
12 reads were kept to estimate the gene abundances in the downstream analysis.
13 Reference guided transcriptome assembly, which compensates incompletely
14 assembled transcripts, was performed by Cufflinks with bias correction for each
15 sample, and then merged into a single unified transcript catalog using Cuffmerge
16 discarding isoforms with abundance below 0.1 in order to remove the low-quality
17 transcripts. As well, differently expressed genes were estimated by Cuffdiff using
18 FPKM [9] (Reads Per Kilobase per Million mapped reads) based on P-value<0.05.

19 **Enrichment analysis**

20 To explore the functional annotation and pathway enrichment of those
21 significantly different genes interactive between the fine and coarse wool, the on-line
22 analysis tool GSEA (GSEA v2.1.0 :<http://software.broadinstitute.org/gsea/msigdb/>)

1 annotate) was used to determine the enriched Gene Ontology (GO) terms and Kyoto
2 Encyclopedia of Genes and Genomes (KEGG) (P-value<0.05).

3 **Quantitative real time PCR (RT-PCR) validation**

4 Three animals with fine wool (fiber diameter, FD<21.0µm) and three animals
5 with coarse wool (fiber diameter, FD>27.0µm) were selected. A piece of skin
6 (approximately 0.5cm²) on the body side was cut off and frozen immediately in liquid
7 nitrogen for the subsequent qRT-PCR analysis. Total RNA was extracted using Trizol
8 (TaKaRa) following the manufacturer's protocols. The total RNA obtained was
9 re-suspended in nuclease-free water and the concentration was measured using
10 Nanodrop (Thermo Scientific Nanodrop 2000). Approximately 0.5 µg of total RNA
11 was used as template to synthesize the first-strand cDNA using a PrimerScript RT
12 reagent Kit (TaKaRa) following the manufacturer's protocols. The resultant cDNA
13 was diluted to 0.1 µg/µl for further analysis in the qRT-PCR (Bio-Rad) using a SYBR
14 Green Realtime PCR Master Mix (TaKaRa). The GAPDH gene was chosen as
15 internal reference to eliminate sample-to-sample variation. The relative gene
16 expression levels were calculated using the 2^{-ΔCt} method. The differential expression
17 genes between fine and coarse wool skin samples were analyzed by GLM using SAS
18 software 9.0.

19

20 **Results**

21 **Skin transcriptome profiling of differential diameter**

22 The cDNA libraries of six skin samples from two groups of fine wool sheep with
23 different fiber diameters (3 samples for FD<21.0µm and 3 samples for FD>27.0µm)

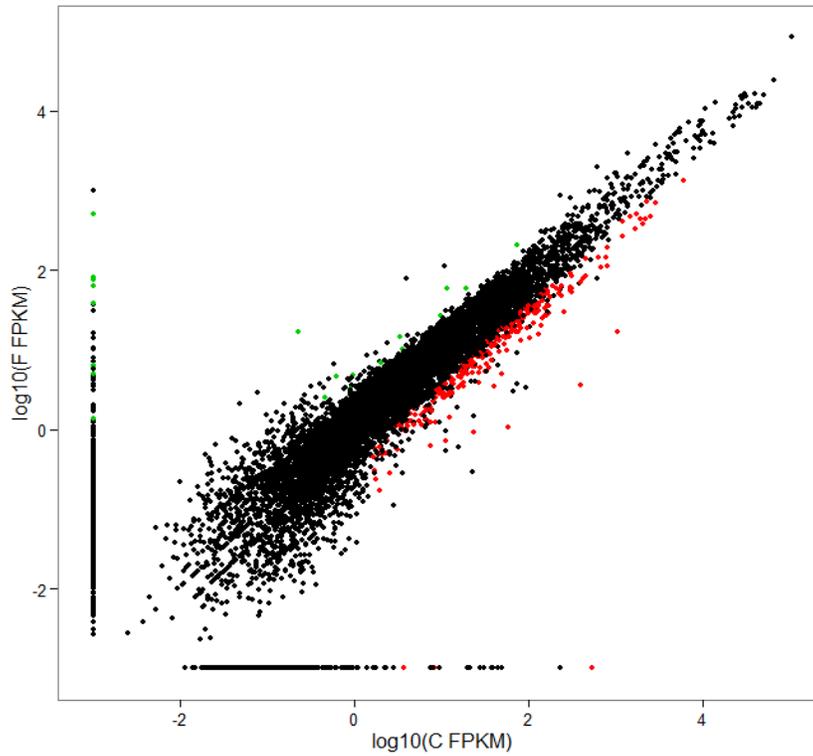

1 were sequenced. In total, 35,884,100-55,926,820 paired-end reads of 100 bp in length
2 were obtained per sample. As a result, the total read length was 28.6 gigabases (Gb)
3 for the six samples. Alignment of the sequence reads against the *Ovis aries* 3.1
4 reference genome sequence (<http://www.ncbi.nlm.nih.gov/genome/?term=sheep>)
5 yielded 78.88%±3.84% of uniquely aligned reads across the six samples, of which
6 63-67% was in annotated exons, 10-11% was located in introns, and the remaining
7 22-27% was assigned to intergenic regions. Unmapped or multi-position matched
8 reads (7.6-8.5%) were excluded from further analyses. Consequently, 19914 mRNA
9 transcripts were detected as expressed (FPKM>0) in the six skin samples (Additional
10 file1:Table S1). Among these, there were several well-known genes affecting skin
11 cycle (e.g., *KRTAP7-1* , *KRT14* , *Wnt10b* , *Wnt2b*, *β-catenin* , and *FGF5*).

12 **Differential gene expression between two groups for fine wool and coarse wool**

13 Using Cuffdiff methods [9], the differential gene expression profile between the
14 Erdos fine wool sheep with large and small fiber diameters were examined. In total,
15 467 expressed genes were detected as significantly different on the basis of the
16 threshold value ($P<0.05$, $|\log_2\text{Ratio}|>1.4$). The expression levels of 21 of the 467
17 genes were upregulated in the sheep with small fiber diameter; the other 446 genes
18 showed higher expression in the sheep with coarse wool (Figure 1 and Table S2).

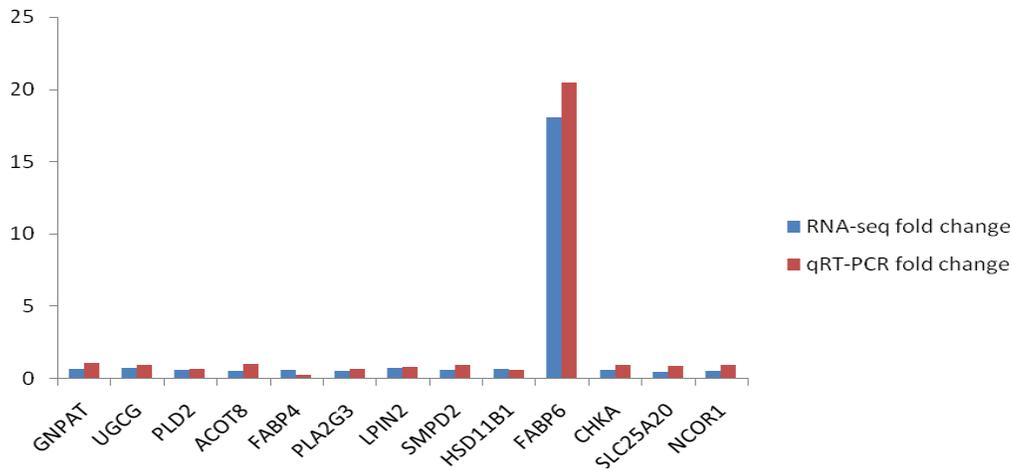

19 The reliability of the RNA-Seq data and the sampling accuracy of the skin tissue
20 used in this study were confirmed by qRT-PCR of 13 randomly selected genes. The
21 13 differentially expressed genes included *GNPAT*, *UGCG*, *PLD2*, *ACOT8*, *FABP4*,
22 *PLA2G3*, *LPIN2*, *SMPD2*, *HSD11B1*, *FABP6*, *CHKA*, *SLC25A20* and *NCOR1*. For

1 these selected 13 genes, the correlation between the mRNA expression level from
2 qRT-PCR and RNA-Seq were high (correlation coefficient = 0.999, $P < 0.05$),
3 confirming the high reproducibility of RNA-Seq data in this study (Figure 2 and Table
4 S3).

7

8 Gene Ontology enrichment and pathway analysis

9 To further investigate the functional association of the 467 differential expressed
 10 genes, gene ontology (GO) analysis using the on-line analysis tool GSEA
 11 (GSEAv2.1.0 :<http://software.broadinstitute.org/gsea/msigdb/annotate>) was performed.
 12 Several significant GO categories were enriched ($P < 0.05$), including the GO
 13 processes related to lipid metabolism, skin development, differentiation, and immune
 14 function. Such biological processes were involved in collagen catabolism, negative
 15 regulation of macromolecule metabolism, steroid hormone stimulation and lipid
 16 metabolism (Table 2).

1

2 **Discussion**

3 The mechanisms controlling wool/hair traits are complicated. Wool and hair
4 fibers are composed of approximately 90% protein and 1- 9% lipid (dry weight) [10].
5 Thus, synthesis of wool may be linked to lipid metabolism [11]. However, studies on
6 wool traits and regulation mechanisms have been mostly concentrated on the proteins,
7 especially Keratin intermediate filament (KRT-IF) and Keratin-associated proteins
8 (KAPs) [12-14]. The relationship between wool lipids and wool traits, however, has
9 not been examined in detail. Wool lipids are designated as external and structural (or
10 internal) based on their location in the fiber [15]. External lipids, namely wool grease
11 (lanolin) which is secreted from the sebaceous glands attached to the wool follicles,
12 constitutes 10-25% of the wool weight [16]. Internal lipids represent approximately
13 1.5% of the wool weight, consisting mainly of free fatty acids (FFA), sterols and
14 ceramides [17]. Only a few previous studies [18-20] have reported on the wool and
15 hair lipid composition, structural arrangement and physicochemical properties.

1 Recently, researchers have discovered by sheep genome and transcriptome
2 sequencing that some genes involved in skin lipid metabolism, such as *LCE7A* and
3 *MOGAT3*, may be related to wool synthesis [11]. Employing X-ray and molecular
4 dynamics simulation, analysis of the effect of the internal lipids on alpha-keratin
5 protein showed that excess internal hair lipids intercalate a dimer of keratin to
6 disorganize the ordered keratin structure [10]. To demonstrate the important role of
7 lipids on hair keratin structure, Cruz *et al.* (2013) removed the lipids from the
8 simulated keratin/lipids mixture to allow the keratin to organize itself. As lipids
9 intercalate with keratin structure, they may affect the tensile strength of the hair
10 keratin. Moreover , higher lipid content may have the ability to interact and interfere
11 with the structure of keratin fibers, which may influence in the texture of the hair or
12 wool [10]. A study by Duvel *et al.* [21] showed that decreased free polar lipid
13 concentrations and covalently bound fatty acids from the root to the tip of the hair
14 markedly decreased tensile properties. All of these studies indicate that the lipid
15 metabolism has close relevance to wool synthesis, and may even affect wool traits.

16 In the present study, the gene expression profiles of sheep skin with fine and
17 coarse wool were compared. There were 467 differentially expressed genes detected,
18 and a large proportion of these genes were enriched in several significant GO
19 processes related to lipid metabolism and a number of genes were found to be
20 involved in the metabolism of lipids and lipoproteins using KEGG pathway analysis.
21 These findings, together with previous studies, suggest that lipid metabolism may be
22 an important mechanism affecting wool synthesis and properties.

1 The phospholipase gene family encodes enzymes that hydrolyze phospholipids
2 into fatty acids and other lipophilic molecules. This gene family is classified into four
3 major classes, namely, phospholipase *PLA*, *PLB*, *PLC* and *PLD* [22,23], based on the
4 types of catalytic reaction of phospholipids. The majority of coding enzymes play
5 crucial roles in lipid metabolism, cell proliferation, muscle contraction and
6 inflammation [24-28]. *PLA2G3* (group III phospholipase A2) in mammals is a
7 multi-domain protein with a central 150 amino acid (AA) *PLA2* domain flanked by
8 N-terminal (130 AA) and C-terminal (219 AA) extensions of unknown function [29].
9 It was shown recently that *PLA2G3* contributes to sperm maturation, development of
10 atherosclerosis in mice, and mast cell maturation and function in addition to other
11 roles [25,30,31]. *PLD2* (phospholipase D2) gene is widely expressed in various
12 tissues, and two transcript variants encoding different isoforms have been found for
13 this gene [32]. In addition to the common roles of the phospholipase gene family,
14 *PLD2* has been also discovered recently to catalyze a transphosphatidylation reaction
15 to produce a phosphatidylalcohol, a potential lipid messenger regulating keratinocyte
16 proliferation and differentiation [33]. This protein localizes to the peripheral
17 membrane and may be involved in cytoskeletal organization, cell cycle control,
18 transcriptional regulation, and/or regulated secretion.

19 Intracellular fatty acid-binding proteins (FABPs) are members of a multigene
20 family encoding ~ 5-kDa proteins, which bind a hydrophobic ligand in a
21 non-covalent, reversible manner [34,35]. These proteins are thought to have various
22 functions including fatty acid uptake, transport, and metabolism [36-41]. Nine

1 separate mammalian FABPs have been identified to date, and each has unique
2 tissue-specific distribution pattern [42,43]. *FABP4* encodes the fatty acid-binding
3 protein found in adipocytes, and is used to predict the development of the metabolic
4 syndrome independently of pubertal status, adiposity, and insulin resistance [44,45].
5 The FABP6 protein is found in the ileum, ovary and adrenal gland [42,46,47], and has
6 been hypothesized to function as a cytosolic receptor for bile acids transported by the
7 sodium dependent action of the ileal bile-acid transporter [42,48]. In the present study,
8 both proteins were found to be expressed in skin, indicating that FABPs may have
9 other roles.

10 Lipin family proteins, including lipin1, lipin2 and lipin3, are emerging as critical
11 regulators of lipid metabolism. Specifically, they act as phosphatidate phosphatase
12 (PAP) enzymes required for glycerolipid biosynthesis and as transcriptional
13 coactivators that regulate expression of lipid metabolism genes [48,49]. Each of the
14 three lipin genes exhibits a unique pattern of tissue expression, suggesting
15 independent physiological roles. Lipin2 (*LPIN2*) is expressed in many tissues
16 including liver, kidney, brain, and lung [50]. Several missense mutations in *LPIN2*
17 have been associated with psoriasis [51]. Also, homozygous and compound
18 heterozygous mutations in human *LPIN2* lead to Majeed Syndrome characterized by
19 recurrent multifocal inflammation of bone and skin, fever, and dyserythropoietic
20 anemia [52-55]. These findings suggest *LPIN2* functions are crucial for normal skin
21 metabolism.

22 11β -Hydroxysteroid dehydrogenase 1 (*HSD11B1*) is a member of the short chain

1 dehydrogenase/reductase superfamily [56]. The first mammalian *HSD11B1* to be
2 cloned was a cDNA from rat liver, and analysis indicated an 861-bp open reading
3 frame encoding a protein of 288 amino acids. Subsequently, cDNA sequences have
4 been published for many species including humans, which are over 30 kb in length
5 and consist of 6 exons and 5 introns [56]. *HSD11B1* has been identified in a wide
6 variety of tissues [56,57], including skin [58]. *HSD11B1* is an endoplasmic reticulum
7 membrane enzyme and serves primarily to catalyze reversibly the conversion of
8 cortisol to the inactive metabolite cortisone, and the conversion of 7-ketocholesterol
9 to 7-beta-hydroxycholesterol [56,57,59]. Recent observations also indicated a role for
10 *HSD11B1* in oxysterol metabolism and in bile acid homeostasis [59]. Too much
11 cortisol can lead to Cushing's syndrome [60]. Patients with this disease have severe
12 skin atrophy and impaired wound healing [61]. Therefore, it is considered that topical
13 *HSD11B1* inhibition could have a beneficial impact on the ageing skin phenotype and
14 wound healing [56,60].

15

16 **Conclusions**

17 This study has greatly expanded our comprehension of molecular mechanisms
18 affecting wool properties particularly wool fineness and potentially human hair
19 texture. Differences were found in the expressed genes suggested GO categories and
20 pathways between the two groups with different wool fiber diameters that may be
21 related to wool fineness. These findings provide a better understanding of wool
22 physiology and will be useful for identification of genes associated with wool

1 diameter.
