Abstract

Entomopathogenic nematodes (EPNs) employ a sophisticated chemosensory apparatus to detect potential hosts. Understanding the molecular basis of relevant host-finding behaviours could facilitate improved EPN biocontrol approaches, and could lend insight to similar behaviours in economically important mammalian parasites. FMRFamide-like peptides are enriched and conserved across the Phylum Nematoda, and have been linked with motor and sensory function, including dispersal and aggregating behaviours in the free living nematode *Caenorhabditis elegans.* The RNA interference (RNAi) pathway of *Steinernema*

carpocapsae was characterised *in silico,* and employed to knockdown the expression of the

FMRFamide-like protein 21 (GLGPRPLRFamide) gene (*flp-21*) in *S. carpocapsae* infective

juveniles; a first instance of RNAi in this genus, and a first in an infective juvenile of any EPN

species. Our data show that 5 mg/ml dsRNA and 50 mM serotonin triggers statistically

significant *flp-21* knockdown (-84%***) over a 48 h timecourse, which inhibits host-finding

(chemosensory), dispersal, hyperactive nictation and jumping behaviours. However, whilst 1

mg/ml dsRNA and 50 mM serotonin also triggers statistically significant *flp-21* knockdown (-

51%**) over a 48 h timecourse, it does not trigger the null sensory phenotypes; statistically

significant target knockdown can still lead to false negative results, necessitating appropriate

experimental design. SPME GC-MS volatile profiles of two EPN hosts, *Galleria mellonella*

and *Tenebrio molitor* reveal an array of shared and unique compounds; these differences

had no impact on null *flp-21* RNAi phenotypes for the behaviours assayed. Localisation of

flp-21 / FLP-21 to paired anterior neurons by whole mount *in situ* hybridisation and

immunocytochemistry corroborates the RNAi data, further suggesting a role in sensory

modulation. These data can underpin efforts to study these behaviours in other

economically important parasites, and could facilitate molecular approaches to EPN strain

improvement for biocontrol.

Author summary

Entomopathogenic nematodes (EPNs) use a range of behaviours in order to find a suitable

host, some of which are shared with important mammalian parasites. The ethical burden of

conducting research on parasites which require a mammalian host has driven a move

towards appropriate 'model' parasites, like EPNs, which have short life cycles, can be

cultured in insects or agar plates, and have excellent genomic resources. This study aimed

to develop a method for triggering gene knockdown by RNA interference, a biochemical

pathway involved in gene regulation. Through knocking down the expression of a target

gene we can then study the function of that gene, helping us to understand the molecular

basis of behaviour. Here we have characterised the RNAi pathway of *Steinernema*

carpocapsae through analysing the genome sequence for relevant genes, and have

successfully knocked down the neuropeptide gene *flp-21* in *S. carpocapsae* infective

juveniles. We find that it is involved in the regulation of behaviours which rely on sensory

perception and relate to host-finding. We have localised the gene and mature neuropeptide,

and find them to be expressed in paired anterior neurons, which is in broad agreement with

our behavioural observations following RNAi. Our observations are relevant to interactions

of *S. carpocapsae* with two insect hosts, the waxworm *Galleria mellonella*, and the

meelworm, *Tenebrio molitor*. We identified the volatile compounds relating to both insects,

and find that there are both shared and unique compounds to both species; EPNs use

volatile compound gradients, as well as other physical cues in order to find and invade a

host. This study provides a method for employing RNAi in a promising model parasite, and

characterises the molecular basis of host-finding behaviours which could be relevant to

economically important mammalian parasites. EPNs are also used as bioinsecticides, and

so understanding their behaviour and biology could have broad benefits across industry and

academia.

Introduction

Entomopathogenic nematodes (EPNs) borrow their name from the entomopathogenic

bacteria (*Photorhabdus*, *Serratia* and *Xenorhabdus* spp.) with which they form a commensal

relationship. These nematodes provide a stable environment for the bacteria, and act as a

vector between insect hosts. Once the nematode has invaded an insect, the nematode

exsheaths (or 'recovers') and entomopathogenic bacteria are regurgitated into the insect

haemolymph; the bacteria then rapidly kill and metabolise the insect, providing nutrition and

developmental cues for the nematode. These entomopathogenic bacteria are then

transmitted between nematode generations (1). The entomopathogenic lifestyle has been

found to arise independently in nematodes, at least three times, spanning significant

phylogenetic diversity. *Heterorhabditis* and *Oscheius* spp. (2) reside within clade 9 along

with major strongylid parasites of man and animal (3); Steinernema spp. reside within clade

10 alongside strongyloidid parasites (4).

Nictation is a dispersal and host-finding strategy, enacted by nematodes which stand upright

on their tails, waving their anterior in the air (5). This behaviour is shared amongst many

economically important animal parasitic and entomopathogenic nematodes, alongside the

model nematode *C. elegans*, for which nictation is a phoretic dispersal behaviour of dauer

larvae, used to increase the likelihood of attachment to passing animals. Nictation is

regulated by amphidial IL2 neurons in *C. elegans*, which occur in lateral triplets either side of

the pharyngeal metacorpus (5, 6). IL2 neurons display significant remodelling from *C.*

elegans L3 to dauer (the only life-stage to enact nictation behaviours) such that connectivity

with other chemosensory and cephalic neurons is enhanced (6). It has been shown that IL2

neurons express the DES-2 acetylcholine receptor subunit, and that cholinergic signalling is

requisite for nictation (5, 7-9). Additionally, the central pair of IL2 neurons express the

FMRFamide-like peptide (FLP) receptor, NPR-1 (10). To date there are two known NPR-1

agonists; FLP-18 and FLP-21 (11). However, there is also known redundancy of FLP-18

and FLP-21 in signalling through other neuropeptide receptors (NPR-4, -5, -6 -10, -11, and

NPR-2, -3, -5, -6, 11, respectively) in heterologous systems (12, 13), making functional

linkage difficult. *Steinernema* spp. also display a highly specialised jumping behaviour which

is thought to enhance both dispersal and host attachment. Jumping occurs when a nictating

infective juvenile (IJ) unilaterally contracts body wall muscles bringing the anterior region

towards the posterior region, forming a loop. This generates high pressure within the IJ

pseudocoel, and differential stretching and compression forces across the nematode cuticle.

Release of this unilateral contraction, in conjunction with the correction of cuticle pressure,

triggers enough momentum for an IJ to jump a distance of nine times body length, to a

height of seven times body length (14). Here we aimed to study the function of *Sc-flp-21* in

coordinating nictation and other behaviours relevant to host-finding.

The recent publication of five *Steinernema* spp. genomes, along with stage-specific

transcriptomes (15) represents a valuable resource, alongside the previously published

genomes of *Oscheius* sp. TEL-2014 (16) and *Heterorhabditis bacteriophora* (17). The

genome of *Steinernema carpocapsae* is the most complete, at an estimated 85.6 Mb, with

predicted coverage of 98% (15). *S. carpocapsae* was selected as a test subject for our

study due to the quality of genome sequence. The close phylogenetic relationship between

Steinernema spp. coupled with a diverse behavioural repertoire, particularly in terms of host-

finding (18, 19), make this genus an extremely attractive model for comparative

neurobiology. The aim of this study was to examine RNAi functionality in *S. carpocapsae*

IJs, and to probe the involvement of FLP-21 in coordinating sensory perception (host-finding,

nictation, jumping and dispersal phenotypes), as a prelim to probing the neuronal and

molecular underpinnings of host-finding behaviour in this genus.

Materials and Methods

S. carpocapsae culture

S. carpocapsae (ALL) was maintained in *Galleria mellonella* at 23°C. IJs were collected by

White trap (20) in a solution of Phosphate Buffered Saline (PBS). Freshly emerged IJs were

used for each experiment.

BLAST analysis of *S. carpocapsae* RNAi pathway

BLAST analysis of RNAi pathway components was conducted as in Dalzell et al. (21), using

a modified list of core RNAi pathway components from *C. elegans,* against predicted protein

sets and contigs of the *S. carpocapsae* genome, through the Wormbase Parasite BLAST

server (22, 23).

dsRNA synthesis

Sc-flp-21 (Gene ID: L596_g19959.t1) dsRNA templates were generated from *S. carpocapsae* IJ cDNA using gene-specific primers with T7 recognition sites (see Table 1). Neomycin phosphotransferase (*neo*) and Green Fluorescent Protein (*gfp*) dsRNA templates were generated from pEGFP-N1 (GenBank: U55762.1). Template PCR products were generated as follows: [95 °C x 10 min, 40 x (95 °C x 30 s, 60 °C x 30 s, 72 °C x 30 s) 72 °C x 10 min]. PCR products were assessed by gel electrophoresis, and cleaned using the Chargeswitch PCR clean-up kit (Life Technologies). dsRNA was synthesised using the T7 RiboMAX™ Express Large Scale RNA Production System (Promega), and quantified by a Nanodrop 1000 spectrophotometer.

RNAi

1000 *S. carpocapsae* were incubated in 50 µl PBS with dsRNA and 50 mM serotonin across four experimental regimes; (i) 24 h in 5 mg/ml dsRNA / serotonin / PBS; (ii) 24 h in 5 mg/ml dsRNA / serotonin / PBS, followed by washes to remove the initial dsRNA, and 24 h recovery in PBS only; (iii) 48 h in 5 mg/ml dsRNA / serotonin / PBS; and (iv) 48 h in 1 mg/ml dsRNA and serotonin. Each experiment was conducted at 23 ºC. We found that 50 mM serotonin induced oral uptake of fluorescent dyes under all conditions tested; 50 mM octopamine did not (data not shown).

RNA extraction, cDNA synthesis and quantitative (q)RT-PCR

Total RNA was extracted from 1000 IJs using the Simply RNA extraction kit (Promega, UK) and Maxwell 16 extraction system (Promega, UK). cDNA was synthesised using the High Capacity RNA to cDNA kit (Applied Biosystems, UK). Each individual qRT-PCR reaction comprised 5 µl Faststart SYBR Green mastermix (Roche Applied Science), 1 µl each of the forward and reverse primers (10 µM), 1 µl water, 2 µl cDNA. PCR reactions were conducted in triplicate for each individual cDNA using a Rotorgene Q thermal cycler under the following conditions: [95 °C x 10 min, 40 x (95 °C x 20 s, 60 °C x 20 s, 72 °C x 20 s) 72 °C x 10 min].

Primer sets were optimised for working concentration, annealing temperature and analysed

by dissociation curve for contamination or non-specific amplification by primer–dimer as

standard. The PCR efficiency of each specific amplicon was calculated using the Rotorgene

Q software. Relative quantification of target transcript relative to two endogenous control

genes (*Sc-act* and *Sc-β-tubulin*) was calculated by the augmented ΔΔCt method (24),

relative to the geometric mean of endogenous references (25). One way ANOVA and

Fisher's LSD test were used to analyse data (GraphPad Prism 6). The most similar non-

target gene (*L596_g5821.t1)* was identified using BLASTn against the *S. carpocapsae*

genomic contigs (supplemental figure S1), and primers *Sc-L596_g5821.t1-f* and *Sc-*

L596_g5821.t1-r were used to assess transcript abundance relative to *Sc-act* across control

and experimental conditions for the 48h dsRNA exposure experiments only (Table 1).

Headspace Solid-Phase MicroExtraction (SPME) GC-MS

Approximately 5 g of fresh waxworm (*Galleria mellonella*) and mealworm (*Tenebrio molitor*)

larvae were placed into 20 mL glass tubes and sealed. The holder needle was exposed to

the headspace of the tube over a 120 min timecourse (extraction time) at room temperature

(22 ⁰C). After this time, the SPME syringe was directly desorbed in the GC injection port for

5 min. A fused silica fibre coated with a 95 µm layer of carboxen–polydimethylsiloxane

(CAR–PDMS; Supelco) was used to extract the volatile compounds from the samples.

Fibres were immediately thermally desorbed in the GC injector for 5 min (with this time we

desorb the analytes and re-activated the fiber for the next analysis) at 250 °C and the

compounds were analysed by GC-MS.

A CTC Analytics CombiPal autosampler was coupled to a 7890N Agilent gas chromatograph

(Agilent, Palo Alto, California) and connected to a 5975C MSD mass spectrometer. The

manual SPME holder (Supelco, Bellefonte, PA, USA) was used to perform the experiments.

Chromatographic separation was carried out on 30 m x 0.25 mm I.D. ZB-semivolatiles,

Zebron column (Phenomenex, Macclescfield, UK).The oven temperature was set at 40 ⁰C

for 3 min, temperature increased from 40 to 250 º C at 5 ⁰C min^{-1} and set at the maximum

temperature for 4 min. Helium was used as carrier gas at 1 ml min^{-1}. Mass spectra were

recorded in electron impact (EI) mode at 70 eV. Scan mode was used for the acquisition to

get all the volatile compounds sampled. Quadrupole and source temperature were set at 150

and 230 ⁰C respectively. Compounds were identified using MS data from the NIST library

(>95% confidence).

Dispersal assays

100 *S. carpocapsae* IJs were placed in the centre of a 90 mm PBS agar plate (1.5 % w/v) in

a 5 µl aliquot of PBS. Plates were divided into four zones; a central zone 15 mm in

diameter, and three further zones equally spaced over the remainder of the plate. Plates

were allowed to air dry for ~5 min. Evaporation of the PBS allowed the IJs to begin

movement over the agar surface. Lids were then placed back onto the Petri dishes, and

plates were incubated at 23 °C in darkness for one hour. IJs were counted across central

and peripheral zones and expressed as percentage of total worms. Our subsequent

analysis was conducted on total IJs found within the two central zones. Relative to those

found in the two peripheral zones.

Nictation & jumping assays

3.5 g of compost (John Innes No.2) was placed in a petri dish (55 mm), and dampened

evenly with 150 µl PBS. Approximately ten IJs were pipetted onto the compost in 5 µl of

PBS, and left for 5 minutes at room temperature; this enabled IJs to begin nictating. For the

waxworm volatile challenge, one healthy waxworm (UK Waxworms Ltd.) was placed inside a

1 mL pipette tip, without filter. For the mealworm volatile challenge, two mealworms

(Monkfield Nutrition, UK), weight-matched to the waxworm, were placed inside a 1 mL

pipette tip, without filter. Blank exposure data were captured using an empty 1 ml pipette tip,

without filter. In each case, the pipette was set to eject a volume of 500 µL, comprising air

and the corresponding insect volatiles. A binocular microscope was used to record IJ

behavioural responses following up to five volatile exposures each, on gentle ejection from

the pipette within a distance of ~1 cm of the *S. carpocapsae* IJs. A five second period was

allowed between each volatile exposure. Recording ended for any individual when jumping

was observed or the IJ abandoned a nictating stance (this always corresponded with

migration away from the stimulus). A jumping index was calculated for each treatment group

(1). Additional behavioural observations were recorded, and subsequently reported as

percentage IJs displaying the behaviour over the course of up to five volatile exposures, or

until the IJ migrated / jumped out of the field of vision.

Host finding assay

Two circular holes (approx. 6 mm diameter, centred 4 mm from edge of lid) were drilled either side of a 90 mm petri dish lid. Two microcentrifuge tubes (1.5 ml) with a small hole cut out the bottom (approx. 2mm diameter), were also used for each assay. 200 *S. carpocsae* IJs were placed in the centre of a 90 mm PBS agar plate (1.5 % w/v) in a 5 μl aliquot of PBS. The arena was segmented into positive and a negative zones either side of the plate (25 mm in length from the edge, circling off the plate at a point 60 mm apart; see Fig XA). Plates were allowed to air dry for ~5 min, allowing the IJs to begin migration. The lid was placed on top of the plate, and sealed with parafilm. The 1.5 ml tubes were secured in the holes with parafilm; one remained empty, which we term the blank tube, and the other held four live *Galleria mellonella* fourth instar larvae, or four *Tenebrio molitor* larvae as appropriate. The lid of the tubes were then closed. The plates were incubated at 23 °C in darkness for one hour. IJs were counted in the positive (host side) and negative (blank side) zones and then scored using a chemotaxis index (26). The assay format was adapted from Grewal et al. (1994) (27).

$$Chemotaxis\ Index = \frac{\#\ IJs\ positive\ zone - \#IJs\ negative\ zone}{\#IJs\ in\ both\ zones}$$

Figure 1. (A) image of the final host-finding assay; (B) host-finding assay schematic.

Immunocytochemistry

Freshly emerged *S. carpocapsae* IJs were fixed in 4 % paraformaldehyde overnight at 4 °C,

followed by a brief wash in antibody diluent (AbD; 0.1 % bovine serum albumin, 0.1 %

sodium azide, 0.1 % Triton-X-100 and PBS pH 7.4). The fixed specimens were roughly

chopped on a glass microscope slide with a flat edged razor, and incubated in primary

polyclonal antiserum raised against GLGPRPLRFamide, N-terminally coupled to KLH, and

affinity purified (1:800 dilution in AbD) for 72 h at 4 °C. Subsequently, chopped IJs were

washed in AbD for 24 h at 4 °C, and then incubated in secondary antibody conjugated to

fluorescein isothiocyanate (1:100 dilution in AbD) for 72 h at 4 °C. A further AbD wash for

24 h at 4 °C was followed by incubation in Phalloidin–Tetramethylrhodamine B

isothiocyanate (1:100 dilution in AbD) for 24 h at 4 °C. Finally, chopped IJs were washed in

AbD for 24 h at 4 °C. Specimens were mounted onto a glass slide with Vectasheild

mounting medium and viewed with a Leica TCS SP5 confocal scanning laser microscope.

Controls included the omission of primary antiserum, and pre-adsorption of the primary

antiserum with ≥250 ng of GLGPRPLRFamide. Pre-adsorption in GLGPRPLRFamide did not

alter staining patterns.

Whole mount *in situ* hybridisation

PCR primers were designed to amplify a 200 bp region of *Sc-flp-21* (Gene ID:

L596_g19959.t1) from *S. carpocapse* IJ cDNA. Template PCR products were generated as

follows : [95°C x 10 min, 40 x (95 °C x 30 sec, 60 °C x 30 sec, 72 °C x 30 sec) 72 °C x 10

min]. PCR products were assessed by gel electrophoresis, and cleaned using the

Chargeswitch PCR clean-up kit (Life Technologies). Amplicons were quantified by a

Nanodrop 1000 spectrophotometer. Sense and antisense probes were generated using

amplicons in an asymmetric PCR reaction. The components of each reaction were as

follows: 2.0µl of Reverse primer (or Forward primer for control probe); 2.5µl 10X PCR buffer

with MgCl$_2$ (Roche Diagnostics); 2µl DIG DNA labelling mix (Roche Diagnostics); 0.25µl 10x

Taq DNA polymerase (Roche Diagnostics); 20ng DNA template; distilled water to a volume

of 25µl. Probes were assessed by gel electrophoresis.

Freshly emerged *S. carpocapse* IJs were fixed in 2 % paraformaldehyde in M9 buffer

overnight at 4°C followed by 4h at room temperature. Nematodes were chopped roughly

using a sterile razor blade for 2 minutes and washed three times in DEPC M9.

Subsequently, the chopped nematodes were incubated in 0.4 mg/ml proteinase K (Roche

Diagnostics) for 20 minutes at room temperature. Following three washes in DEPC M9, the

nematodes were pelleted (7000g) and frozen for 15 minutes on dry ice. Subsequently the

nematode sections were incubated for 1 minute in -20°C methanol and then in -20°C

acetone for 1 minute. The nematodes were then rehydrated using DEPC M9 and incubated

at room temperature for 20 minutes, after which three wash steps in DEPC M9 were carried

out to remove any acetone.

The nematodes were pre-hybridised in 150 µl hybridisation buffer (prepared as detailed by

Boer et al., 1998) for 15 minutes. The hybridisation probes were heat denatured at 95°C for

10 minutes, after which they were diluted with 125 µl hybridisation buffer. The probe-

hybridisation mixture was then added to the nematode sections which were incubated at

50°C overnight. Post hybridisation washes were carried out as follows: three washes in 4x

Saline Sodium Citrate buffer (15 minutes, 50°C); three washes in 0.1x SSC/0.1x Sodium

dodecyl sulphate (20 minutes, 50°C) and; 30 minute incubation in 1% blocking reagent

(Roche Diagnostics) in maleic acid buffer (50°C). Subsequently the nematodes were

incubated at room temperature for 2 h in alkaline phosphatase conjugated anti-digoxigenin

antibody (diluted 1:1000 in 1% blocking reagent in maleic acid buffer). Detection was

completed with an overnight incubation in 5-Bromo-4-chloro-3-indolyl phosphate/Nitro blue

tetrazolium at 4°C. The staining was stopped with two washes in DEPC treated water. The

nematode sections were mounted on to glass slides for visualisation.

Statistical analysis

Data pertaining to both qRT-PCR and behavioural assays were assessed by Brown-

Forsythe and Bartlett's tests to examine homogeneity of variance between groups. One-way

or two-way ANOVA was followed by Fisher's Least Significant Difference (LSD) test. All

statistical tests were performed using GraphPad Prism 6.

Results

The RNAi pathway of *S. carpocapsae*

As is the case for other parasitic nematode species, *S. carpocapsae* was found to encode a

less diverse RNAi pathway than that of *C. elegans,* in terms of gene for gene conservation

(21). However, the apparent reduction in AGO homologue diversity is offset by significant

expansions across several putative *ago* genes, to give a predicted overall increase in the *S.*

carpocapsae AGO complement (38 in total), relative to *C. elegans* (24, not including

pseudogenes) (28); WAGO-1 (nineteen), ALG-1 (three), ALG-3 (two), WAGO-5 (four),

WAGO-10 (two), WAGO-11 (three) are all expanded relative to *C. elegans*. Notably, no

identifiable homologue of RDE-1, the primary AGO for exogenously triggered RNAi events in

C. elegans, could be identified (Supplementary table S2).

The presence of PRG-1 and components of the piwi interacting (pi)RNA biosynthetic

machinery suggests that a functional piRNA (or 21U RNA) pathway may be present. Whilst

ERGO-1 is not conserved, two putative ALG-3 orthologues suggest that a functional endo-

siRNA (26G RNA) pathway may also exist, which is supported by broad conservation of

associated proteins. MicroRNA-associated AGOs, ALG-1 and ALG-2 are conserved, with a

small apparent expansion of ALG-1 to three related proteins in *S. carpocapsae*. Further

understanding of how RNAi pathway complements influence functionality will require small

RNA sequencing efforts, and functional genomics approaches.

The RNA-dependent RNA Polymerase (RdRp), RRF-3 is conserved, and known to function antagonistically to exogenously primed RNAi, through competing activity for pathway components required for both exogenous RNAi, and the endo-siRNA (26G RNA) pathway within which RRF-3 operates (29-31). The RdRps, RRF-1 and EGO-1, which are involved in the biosynthesis of secondary siRNAs (22G RNAs) are also conserved. Loss of the argonaute ERGO-1 which functions upstream of secondary siRNA biogenesis in the endo-siRNA (26G RNA) pathway in *C. elegans,* also leads to an exogenous ERI phenotype (Enhanced RNAi), but is not conserved in *S, carpocapsae,* suggesting that ALG-3 / -4 may be solely responsible for endo-siRNA functionality (32, 33).

The apparent absence of the intestinal dsRNA transporter, SID-2 is consistent with findings from other parasitic nematodes (21, 34, 35). SID-1 also appears to be absent, however CHUP-1, a putative cholesterol uptake protein which contains a SID-1 RNA channel is present, and may assist in the intercellular spread of dsRNA. RSD-3, which also effects intercellular spread of dsRNA is conserved (see Figure 1 for pathway overview).

Figure 1. Core RNAi pathway components of *S. carpocapsae* relative to *C. elegans.*

Proteins with at least one putative homologue are represented in colour; those without any

identifiable homologues are colourless. See supplemental tables for information on number

of putative related homologues.

Knockdown of *Sc-flp-21*

Various treatment regimens were employed in order to assess the responsiveness of *S.*

carpocapsae IJs to exogenous dsRNA. 24 h incubation in 5 mg/ml dsRNA, with 50 mM

serotonin was not sufficient to trigger statistically significant *Sc-flp-21* knockdown (Fig. 2A),

however a 24 h dsRNA / serotonin incubation followed by a 24 h recovery in PBS only, did

trigger a small decrease in *Sc-flp-21* relative to *Sc-act* when compared to *gfp* and *neo*

dsRNA controls (0.70 ±0.11, P<0.05) (Fig. 2B). Extended incubation of *S. carpocapsae* IJs

in 5 mg/ml dsRNA and 50 mM serotonin for 48 h triggered robust knockdown of *Sc-flp-21*

(0.16 ±0.07, P<0.0001) (Fig. 2C). 48 h incubation in 1 mg/ml dsRNA, with 50 mM serotonin

also triggered significant levels of *Sc-flp-21* knockdown (0.49 ±0.27, P<0.01), however this

was not as effective as the 5 mg/ml dsRNA treatment (Fig. 2D). A BLAST analysis identified

predicted *S. carpocapsae* transcript *L596_g5821.t* as the non-target gene with most

similarity to the *Sc-flp-21* dsRNA (supplemental figure S1). The relative expression level of

L596_g5821.t1 was unaffected by a 48 h incubation in 5 mg/ml *Sc-flp-21* dsRNA with 50 mM

serotonin, relative to *neo* and *gfp* dsRNA (1.013 ±0.04, P>0.05) (Fig. 2E).

Figure 2. qRT-PCR expression analysis of *Sc-flp-21* and off-target control gene (A) *Sc-*

flp-21 transcript ratio relative to *Sc-act* following 24 h incubation in 5 mg/ml dsRNA, 50 mM

serotonin. (B) *Sc-flp-21* transcript ratio relative to *Sc-act* following 24 h incubation in 5 mg/ml

dsRNA, 50 mM serotonin, and 24 h in PBS; (C) *Sc-flp-21* transcript ratio relative to *Sc-act*

following 48 h incubation in 5 mg/ml dsRNA, 50 mM serotonin; (D) *Sc-flp-21* transcript ratio

relative to *Sc-act* following 48 h incubation in a reduced 1 mg/ml dsRNA, 50 mM serotonin;

(E) *L596_g5821.t1* transcript ratio relative to *Sc-act* following 48 h incubation in 5 mg/ml

dsRNA, 50 mM serotonin. *P<0.05; **P<0.01; ****P<0.0001.

Host insect volatiles

Comprehensive volatile signatures were characterised, and significant differences noted

between *G. mellonella* and *T. molitor* larvae. In total, we identified 10 compounds unique to

G. mellonella, four compounds unique to *T. molitor,* and 14 compounds shared between

both species. These profiles vary significantly from headspace GC-MS data presented by

Hallem et al. (36) for the same insect species (see Table 1).

Table 1. Headspace SPME GC-MS volatile profiles of *Galleria mellonella* and *Tenebrio molitor* larvae

Galleria mellonella	*Tenebrio molitor*	Shared
α-pinene	decanal	nonanal
butanoic acid	1-tetradecanol-methyl ether	hexanoic acid
tetradecanal	1-hexadecanol	octanoic acid
tridecanol	cyclohexadecane	cyclododecane
nonanoic acid		decanoic acid
2-[phenyl methylene]-octanal		dodecanoic acid
tetracosanol		tetradecanoic acid
tridecane		pentadecanoic acid
1-heptacosanol		bis(2-ethylhexyl) ester-hexanedioic acid
cis-9-hexadecenoic acid		hexadecanoic acid
		heptadecanoic acid
		cis-10-heptadecenoic acid
		squalene
		octadecanoic acid

Behavioural impact of *Sc-flp-21* knockdown

S. carpocapsae IJs were challenged by exposure to volatiles from *G. mellonella* or *T. molitor* following RNAi (48 h 5 mg/ml dsRNA, 50 mM serotonin) and control treatments. A decrease in hyperactive nictation following *Sc-flp-21* knockdown was observed (10% ±5.774) relative to untreated (40.75% ±6.75; P<0.01) and *neo* dsRNA treatment (47.5% ±2.5; P<0.001) following *G. mellonella* volatile challenge (Fig. 3A). Likewise, a decrease in hyperactive nictation was observed following *T. molitor* volatile challenge to *Sc-flp-21* RNAi IJs (5.0% ±2.9), relative to untreated (57.25% ±2.8; P<0.0001) and *neo* dsRNA treatment (35.0% ±6.5; P<0.001) (Fig. 3B). A decrease in the jumping index of IJs following *Sc.flp-21* dsRNA

treatment was observed when challenged by *G. mellonella* volatiles (0.08 ±0.03) relative to

untreated (0.69 ±0.11; P<0.001) and *neo* dsRNA treated (0.50 ±0.04; P<0.01) (Fig. 3E) .

Similarly, a decrease in jumping index as a response to *T. molitor* volatiles was observed

following *Sc-flp-21* RNAi (0.03 ±0.03) relative to untreated (0.44 ±0.06; P<0.001) and *neo*

dsRNA treatment (0.38 ±0.05; P<0.001) (Fig 3F). An agar host-finding assay was used to

further assess the impact of *flp-21* knockdown. A decrease in *G. mellonella* finding ability

was observed (0.06 ±0.08) relative to untreated (0.53 ±0.03; P<0.001) and *neo* dsRNA

treated (0.42 ±0.08; P<0.01). Likewise, a decrease in *T. molitor* finding ability was observed

(0.01 ±0.06) relative to untreated (0.32 ±0.04; P<0.05) and *neo* dsRNA treated (0.26 ±0.1;

P>0.05). It was also found that *Sc-flp-21* RNAi resulted in significantly decreased lateral

dispersal, relative to both untreated and *neo* dsRNA treatment (P<0.0001) (Fig. 3G). In all

instances, dsRNA treatment regimens which triggered lower levels of *Sc-flp-21* knockdown

relative to the 48h 5 mg/ml dsRNA, 50 mM serotonin approach, failed to trigger null

phenotypes (data not shown).

Figure 3. *S. carpocapsae* IJ behavioural assays post-RNAi

Behavioural impact of *Sc-flp-21* knockdown following IJ incubation in 5 mg/ml dsRNA, 50

mM serotonin: (A) Mean percentage of *S. carpocapsae* displaying hyperactive nictation upon

challenge by *G. mellonella* volatiles. (B) Mean percentage of *S. carpocapsae* displaying

hyperactive nictation upon challenge by *T. molitor* volatiles. (C) Mean percentage of *S.*

carpocapsae displaying standing upon challenge by *G. mellonella* volatiles. (D) Mean

percentage of *S. carpocapsae* displaying standing upon challenge by *T. molitor* volatiles. (E)

Mean jumping index of *S. carpocapsae* displaying upon challenge by *G. mellonella* volatiles.

(F) Mean jumping index of *S. carpocapsae* upon challenge by *T. molitor* volatiles. (G) Mean

percentage distribution of *S. carpocapsae* IJs across central and peripheral assay zones.

*$P<0.05$; **$P<0.01$; ****$P<0.0001$.

Whole-mount *in situ* hybridisation and Immunocytochemical localisation of *flp-*

***21*/FLP-21 in *S. carpocapsae* IJs**

flp-21/FLP-21 was localised to paired neurons within the central nerve ring region of *S.*

carpocapsae IJs. Without additional neuroanatomical information on *S. carpocapsae* IJs it is

impossible to define these cells, however, based on the immuocytochemical localisation the

cells appear to project posteriorly (Fig. 4). These data suggest that FLP-21 must act as a

modulator of sensory function, downstream of the primary chemosensory neurons

(amphids).

Figure 4. (A) Whole mount *In situ* hybridisation and (B) immunocytochemical

localisation of *flp-21* / FLP-21 (GLGPRPLRFamide) to paired neurons within the

central nerve ring of *S. carpocapsae* IJs. Positive *flp-21* staining is observed as

red/brown pigmentation (A); FLP-21 immunostaining is visible as green, muscle is

counterstained red (B)

Discussion

RNA interference is an extremely important tool for the study of gene function in parasitic nematodes (37, 38). Three independent reports of a functional RNAi pathway in the entomopathogenic nematode *Heterorhabditis bacteriophora* have been published. Ciche and Sternberg (39) assessed the efficacy of RNAi through soaking egg / L1 stage *H. bacteriophora* in 5-7.5 mg/ml dsRNA targeting a number of genes which had been selected on the basis of phenotypic impact on the model *C. elegans*. Demonstrable phenotypes and target transcript knockdown signified an active pathway. Moshayov, Koltai and Glazer (2013)(40) employed the methodology of Ciche and Sternberg (39)to study the involvement of genes in the regulation of IJ exsheathment (or 'recovery'). Subsequently, Ratnappan et al. (41) demonstrated that microinjection was also a suitable method for introducing dsRNA into hermaphrodite gonads, effectively triggering the RNAi pathway in F1 progeny. To date, no such assessment of a functional RNAi pathway has been published for *Steinernema* spp.

The RNAi pathway of *S. carpocapsae* has been characterised by BLAST and validated through silencing *Sc-flp-21* in IJs. Our data indicate that neuronal cells are sensitive to RNAi in *S. carpocapsae* IJs, and that knockdown is highly sequence specific. Like other parasitic nematodes *S. carpocapsae* encodes an expanded set of WAGO-1 (R06C7.1) family AGOs (19 in total) which function primarily with secondary siRNAs (22G RNAs) in *C. elegans,* along with CSR-1 which is also conserved. Whilst RDE-1 is primarily responsible for triggering the onset of an exogenous RNAi response, acting upstream of secondary siRNAs (22G RNAs), it is not conserved in *S. carpocapsae* (21, 31). Our observation of RNAi sensitivity in *S. carpocapsae* reveals that RDE-1 is not required to trigger an exogenous RNAi response, however the functional significance of AGO homologue expansions relative to *C. elegans* remains to be determined. The lack of SID-2 seems to correlate with our observation that relatively high amounts of dsRNA are required to trigger the RNAi pathway by oral delivery.

The nearest non-target gene sequence within the *S. carpocapsae* genome represents an

uncharacterised predicted gene (*L596_g5821.t1*). The *Sc-flp-21* dsRNA shared high levels

of sequence similarity over a 21 bp stretch of *L596_g5821.t1* (20 of 21 bp shared), however

qRT-PCR indicates that *L596_g5821.t1* had not been silenced, which could suggest: (i) the

level of sequence similarity was either insufficient for gene knockdown; (ii) dsRNA was not

diced in the correct register to produce this exact 21 bp sequence within a significant

population of siRNAs; or (iii) the *L596_g5821.t1* gene is not expressed in cells / tissue which

is sufficiently susceptible to dsRNA delivered under the conditions tested. In order to trigger

significant knockdown of *Sc-flp-21,* 48h continuous exposure to dsRNA was required in the

presence of 50 mM serotonin. Reducing dsRNA exposure time lead to a corresponding

reduction in *Sc-flp-21* knockdown, as did a reduction of dsRNA amount from 5mg/ml to

1mg/ml over a 48h time-course. Phenotypes which developed following 48h dsRNA

exposure were not observed across any of the experimental variations which resulted in

decreased gene knockdown (shorter exposure timeframes / lower dsRNA amounts). This

has potentially important implications for RNAi experimental design in other parasitic

nematodes, and notably in *C. elegans*, for which the validation of gene knockdown by qRT-

PCR is not common across the literature. Undoubtedly false negative determinations of

gene function will be a problem in this context. Our data demonstrate that statistically

significant gene knockdown levels are not necessarily sufficient to reveal gene function;

careful consideration should be given to the design of RNAi experiments as a result.

The neuronal RNAi sensitivity of *S. carpocapsae* IJs, and the ease of behavioural assays

makes these species ideal models for studying the neurobiology of sensory perception and

host-finding behaviours. Within the Steinernematid EPNs, a number of species also display

a highly specialised jumping behaviour which can be triggered in nictating IJs on exposure to

host Insect volatiles (18). Silencing *Sc-flp-21* triggers pleiotropic effects on host-finding,

lateral dispersal, hyperactive nictation and jumping phenotypes. The waxworm and

mealworm headspace SPME GC-MS profiles are expanded relative to those presented by

Hallem et al. (36), and likely reflects the increased sensitivity of analysis in this study. These

data could provide a valuable tool for comparative analysis of neurobiology and host-finding

behaviours across EPN species.

Collectively, these data provide the first mechanistic insight to a behaviour which may have

implications for biocontrol efficacy. Through isolating genes and signalling pathways which

coordinate these behaviours, efforts to identify molecular markers of desired behaviours and

traits could facilitate the identification of more suitable isolates and strains for biocontrol use,

and the enhancement of current strains through selective breeding / mutagenic approaches.

The selection or manipulation of behavioural tendencies could lead to strains which are

capable of operating within new ecological niches, expanding their utility.
