35 **ABSTRACT**

36 Tomato leaf mould disease is caused by the biotrophic fungus *Cladosporium fulvum*. During
37 infection, *C. fulvum* produces extracellular small secreted protein (SSP) effectors that
38 function to promote colonization of the leaf apoplast. Resistance to the disease is governed by
39 *Cf* immune receptor genes that encode receptor-like proteins (RLPs). These RLPs recognize
40 specific SSP effectors to initiate a hypersensitive response (HR) that renders the pathogen
41 avirulent. *C. fulvum* strains capable of overcoming one or more of all cloned *Cf* genes have
42 now emerged. To combat these strains, new *Cf* genes are required. An effectormics
43 approach was employed to identify wild tomato accessions carrying new *Cf* genes.
44 Proteomics and transcriptome sequencing were first used to identify 70 apoplastic *in planta*-
45 induced *C. fulvum* SSPs. Based on sequence homology, 61 of these SSPs were novel or
46 lacked known functional domains. Seven, however, had predicted structural homology to
47 antimicrobial proteins, suggesting a possible role in mediating antagonistic microbe–microbe
48 interactions *in planta*. Wild tomato accessions were then screened for HR-associated
49 recognition of 41 SSPs using the *Potato virus X*-based transient expression system. Nine
50 SSPs were recognized by one or more accessions, suggesting that these plants carry new *Cf*
51 genes available for incorporation into cultivated tomato.

56

57 **INTRODUCTION**

58 Leaf mould disease of tomato (*Solanum lycopersicum*) is caused by the biotrophic
59 Dothideomycete fungal pathogen *Cladosporium fulvum* (syn. *Passalora fulva* and *Fulvia*
60 *fulva*) (Thomma et al., 2005). The fungus likely originated in South America, the centre of
61 origin for tomato (Jenkins, 1948), with the first disease outbreak reported in South Carolina,
62 USA, during the late 1800s (Cooke, 1883). *C. fulvum* now occurs worldwide, but is primarily
63 a problem in greenhouse and high-tunnel environments, where tomato plants are exposed to
64 both moderate temperatures and high relative humidity. Disease symptoms are typified by
65 pale green to yellow spots on the adaxial leaf surface, as well as white to olive-green patches
66 of mould on the abaxial leaf surface that turn brown upon sporulation. In the late stages of
67 disease development, this sporulation is often associated with leaf wilting and partial
68 defoliation, which, in severe infections, can cause death of the plant (Thomma et al., 2005).

69 During infection (i.e. in a compatible interaction), *C. fulvum* exclusively colonizes the
70 tomato leaf apoplast, where it grows in close contact with surrounding mesophyll cells
71 (Thomma et al., 2005). This colonization is promoted through a collection of virulence
72 factors, termed effector proteins, which the fungus secretes into the apoplastic environment
73 (e.g. Laugé et al., 1997). To date, 13 *C. fulvum* effectors have been identified, and the genes
74 encoding these proteins have been cloned (Bolton et al., 2008; Joosten et al., 1994; Laugé et
75 al., 2000; Luderer et al., 2002a; Mesarich et al., 2014; Ökmen et al., 2013; Stergiopoulos et
76 al., 2012; van den Ackerveken et al., 1993; van Kan et al., 1991; Westerink et al., 2004). The
77 majority (11 of 13) are small secreted proteins (SSPs) of less than 300 amino acid residues in
78 length with: (i) an amino (N)-terminal signal peptide for secretion into the tomato leaf
79 apoplast; and (ii) four or more cysteine (Cys) residues following their signal peptide cleavage
80 site. An intrinsic virulence function has been determined for three of the 11 SSP effectors.
81 The first of these, Avr2, which lacks a known functional domain, targets and inhibits at least
82 four Cys proteases of tomato (Rcr3, Pip1, aleurain and TDI-65) to prevent the degradation of
83 *C. fulvum* proteins (Krüger et al., 2002; Rooney et al., 2005; Shabab et al., 2008; van Esse et
84 al., 2008). The second, Avr4, possesses a carbohydrate-binding module family domain
85 (CBM_14; PF01607) that binds chitin present in the cell wall of *C. fulvum* to protect against
86 hydrolysis by basic plant chitinases (van den Burg et al., 2004, 2006; van Esse et al., 2007).
87 The third, Ecp6, possesses three lysin motif domains (LysM; PF01476) that function to
88 perturb chitin-triggered immunity (Bolton et al., 2008; de Jonge et al., 2010; Sánchez-Vallet
89 et al., 2013). More specifically, two of the LysM domains cooperate to sequester chitin
90 fragments released from the cell wall of invading hyphae, and in doing so, outcompete host
91 chitin immune receptors for the binding of chitin fragments (Sánchez-Vallet et al., 2013). The
92 third LysM domain has been proposed to perturb chitin-triggered immunity through
93 interference with the host chitin immune receptor complex (Sánchez-Vallet et al., 2013).

94 Despite their roles in virulence, the same effectors can also be an Achilles' heel for
95 *C. fulvum*. In particular accessions of tomato, these effectors or their modulated targets can be
96 directly or indirectly recognized, respectively, as invasion patterns (IPs) by corresponding Cf
97 immune receptors to trigger immune responses that render the pathogen avirulent (Cook et
98 al., 2015; de Wit et al., 2009; Wulff et al., 2009b). In these incompatible interactions, the
99 main output of the immune system is the hypersensitive response (HR), a localized form of
100 cell death that arrests growth of the pathogen at the infection site (Heath, 2000). So far, 10 of
101 the 11 *C. fulvum* SSP effectors, specifically Avr2, Avr4, Avr4E, Avr5, Avr9, Ecp1, Ecp2-1,
102 Ecp4, Ecp5 and Ecp6, are known to be recognized as IPs in tomato accessions with the

103 corresponding Cf immune receptors Cf-2.1/Cf-2.2, Cf-4, Cf-4E, Cf-5, Cf-9, Cf-Ecp1,
104 Cf-Ecp2-1, Cf-Ecp4, Cf-Ecp5 and Cf-Ecp6, respectively (de Wit et al., 2009; Thomma et al.,
105 2011). All Cf immune receptor genes cloned to date encode receptor-like protein (RLP) cell
106 surface receptors that possess extracytoplasmic leucine-rich repeats (eLRRs), a
107 transmembrane domain, and a short cytoplasmic tail (Dixon et al., 1996, 1998; Jones et al.,
108 1994; Panter et al., 2002; Takken et al., 1999; Thomas et al., 1997). Several studies suggest
109 that the eLRRs are responsible for the direct or indirect recognition of *C. fulvum* effector
110 proteins in the tomato leaf apoplast (Seear and Dixon, 2003; van der Hoorn et al., 2001a;
111 Wulff et al., 2001, 2009a).

112 It was determined early on that wild *Solanum* species and landraces are a rich source
113 of resistance against *C. fulvum*. Indeed, all cloned Cf immune receptor genes are derived from
114 wild *Solanum* species or landraces, with Cf-2.1/Cf-2.2, Cf-9/Cf-9DC and Cf-9B from
115 *Solanum pimpinellifolium* (Dixon et al., 1996; Jones et al., 1994; Panter et al., 2002; van der
116 Hoorn et al., 2001b), Cf-4 and Cf-4E from *Solanum habrochaites* (Takken et al., 1999;
117 Thomas et al., 1997), and Cf-5 from the landrace *Solanum lycopersicum* var. *cerasiforme*
118 (Dixon et al., 1998). Based on this knowledge, Cf immune receptor genes were introgressed
119 from wild *Solanum* species and landraces into cultivated tomato by breeders over several
120 decades (Kerr and Bailey, 1964 and references therein). While largely effective, intensive
121 year-round cultivation of these plants has led to the emergence of natural *C. fulvum* strains
122 capable of overcoming one or more of all cloned Cf immune receptor genes (Hubbeling,
123 1978; Iida et al., 2015; Laterrot, 1986; Li et al., 2015). Several types of sequence
124 modification have been shown to occur in IP effector genes that permit the evasion of Cf
125 immune receptor-mediated resistance by *C. fulvum*. These are: (i) gene deletion; (ii) the
126 insertion of a transposon-like element (gene disruption); (iii) single nucleotide
127 polymorphisms (SNPs) that result in non-synonymous amino acid substitutions; and (iv)
128 nucleotide insertions or deletions (indels) that result in frame-shift mutations (Stergiopoulos
129 et al., 2007). To combat strains capable of overcoming existing resistance specificities, new
130 Cf immune receptor genes need to be identified for incorporation into cultivated tomato.

131 Laugé et al. (2000) hypothesized that “any stable, extracellular protein produced by a
132 pathogen during colonization is a potential avirulence factor [IP]”. With this in mind, and
133 given that all cloned Cf immune receptor genes encode an RLP, we set out to identify wild
134 tomato accessions carrying new Cf immune receptor genes corresponding to apoplastic *in*
135 *planta*-induced SSPs (ipiSSPs) of *C. fulvum* using effectoromics. Effectoromics is a powerful
136 high-throughput functional genomics approach that uses effectors or effector candidates to

137 probe plant germplasm collections for corresponding immune receptors (Domazakis et al.,
138 2017; Du and Vleeshouwers, 2014; Vleeshouwers and Oliver, 2014). Notably, this approach,
139 which is based on the HR-associated recognition of effectors or effector candidates, has
140 already proven to be successful for the identification of wild accessions and breeding lines of
141 *Solanum* carrying *Cf* immune receptor genes corresponding to known effectors of *C. fulvum*.
142 In a pioneering study by Laugé et al. (1998), 21 *S. lycopersicum* lines originating from early
143 *C. fulvum* resistance breeding programmes were screened for their ability to recognize
144 Ecp2-1 using the *Potato virus X* (PVX)-based transient expression system (Hammond-
145 Kosack et al., 1995; Takken et al., 2000), as well as by leaf injection with purified Ecp2-1
146 protein. Four lines, which have the same *S. pimpinellifolium* ancestor, recognized Ecp2-1,
147 indicating for the first time that tomato carries an immune receptor gene corresponding to this
148 effector (*Cf-Ecp2-1*) (Laugé et al., 1998).

149 In a follow-up study by Laugé et al. (2000), 28 *S. lycopersicum* breeding lines, many
150 of which also have an *S. pimpinellifolium* ancestor, were screened for their ability to
151 recognize purified Ecp1, Ecp2-1, Ecp3 (amino acid sequence not yet known), Ecp4 or Ecp5
152 protein. Four lines recognized Ecp2-1, while two different lines recognized Ecp3 and Ecp5,
153 respectively (Laugé et al., 2000). In the same study, a collection of 40 different
154 *S. pimpinellifolium* accessions were also screened for their ability to recognize the same five
155 effectors, as well as Avr4 and Avr9, using the PVX-based transient expression system. Three
156 different accessions recognized Ecp1, Ecp2-1 and Ecp3 (purified protein), respectively, while
157 two recognized Ecp4, three recognized Ecp5, and six recognized Avr9 (Laugé et al., 2000).
158 Again, this study indicated for the first time that tomato carries immune receptor genes
159 corresponding to Ecp3 (*Cf-Ecp3*), Ecp4 (*Cf-Ecp4*) and Ecp5 (*Cf-Ecp5*) (Laugé et al., 2000).
160 Three known *C. fulvum* effectors have since been shown to be recognized by wild tomato
161 accessions through infiltration of purified protein, specifically Ecp6 in *S. lycopersicum*
162 (Thomma et al., 2011), as well as Avr4 and Avr9 in *S. pimpinellifolium* (Kruijt et al., 2005;
163 van der Hoorn et al., 2001b).

164 As a starting point for our effectoromics approach, we used proteomics and
165 transcriptome sequencing to identify 70 apoplastic ipiSSPs of *C. fulvum*. This set of 70 is
166 made up of all 11 known SSP effectors of this fungus, as well as 59 *C. fulvum* candidate
167 effectors (CfCEs). We screened 41 of these ipiSSPs for HR-associated recognition by wild
168 tomato accessions using the PVX-based transient expression system. A total of nine ipiSSPs,
169 renamed as extracellular proteins (Ecps), were recognized by one or more of 14 wild tomato

170 accessions, suggesting that these plants carry new *Cf* immune receptor genes available for
171 incorporation into cultivated tomato.

172

173 RESULTS

174 Proteomics and transcriptome sequencing identify 70 apoplastic ipiSSPs of *C. fulvum*.

175 Liquid-chromatography–tandem mass spectrometry (LC–MS/MS) was used to identify
176 fungal peptides corresponding to SSPs present in intercellular washing fluid (IWF) samples
177 of compatible *C. fulvum*–tomato (*S. lycopersicum* cv. Heinz [H]-Cf-0) interactions. Here,
178 SSPs are defined as those proteins of less than 300 amino acid residues in length with a
179 predicted N-terminal signal peptide, but without a predicted glycosylphosphatidylinositol (GPI)
180 anchor modification site, one or more transmembrane domains, a carboxyl (C)-terminal
181 endoplasmic reticulum (ER) retention (H/KDEL)/retention-like (XXEL) signal, or sequence
182 homology to enzymes. Using this approach, 297 unique fungal peptides were mapped to 75
183 SSPs of *C. fulvum* (Table S1 and Information S1). Based on pre-existing RNA-Seq
184 transcriptome sequencing data from a compatible *C. fulvum* strain 0WU–*S. lycopersicum* cv.
185 H-Cf-0 interaction at 4, 8 and 12 d post-inoculation (dpi), as well as from *C. fulvum* strain
186 0WU grown *in vitro* in potato-dextrose broth (PDB) or Gamborg B5 liquid media at 4 dpi
187 (Mesarich et al., 2014), 70 of the 75 apoplastic SSPs (~93.3%) were deemed to be encoded
188 by *in planta*-induced genes (Tables 1 and S1).

189 Amongst the 70 apoplastic ipiSSPs are all *C. fulvum* SSP effectors identified in
190 previous studies (Avr2, Avr4, Avr4E, Avr5, Avr9, Ecp1, Ecp2-1, Ecp4, Ecp5, Ecp6 and
191 Ecp7) (Bolton et al., 2008; Joosten et al., 1994; Laugé et al., 2000; Luderer et al., 2002a;
192 Mesarich et al., 2014; van den Ackerveken et al., 1993; van Kan et al., 1991; Westerink et al.,
193 2004), as well as 32 of 43 (~74.4%) *C. fulvum* candidate effectors (CfCEs) recently
194 discovered using a combined bioinformatic and transcriptome sequencing approach
195 (Mesarich et al., 2014) (Table S1). The latter includes CfPhiA-1 (CfCE11), a phialide protein
196 previously identified in the IWF sample of a compatible *C. fulvum* (strain IPO 1979)–tomato
197 (*S. lycopersicum* cv. Moneymaker [MM]-Cf-0) interaction at 14 dpi (Bolton et al., 2008).

198 Strikingly, 62 of the 70 apoplastic ipiSSPs (~88.6%) are both Cys-rich (≥ 4 Cys
199 residues) and have an even number of Cys residues (Tables 1 and S1). With the exception of
200 putative propeptide kexin protease cleavage (LXKR) and N-linked glycosylation (NXS/T)
201 sites, no shared motifs were identified between five or more of the 70 ipiSSPs. In total, six
202 ipiSSPs, specifically CfCE16, CfCE20, CfCE33, CfCE40, CfCE66 and CfCE72, possess an
203 LXKR motif (Information S1). In all but one of these ipiSSPs (CfCE72), this motif is located

204 between the predicted signal peptide cleavage site and the first Cys residue (Information S1).
205 A similar motif (LXPR) is located between the predicted signal peptide cleavage site and the
206 first Cys residue of CfCE33 and CfCE67 (Information S1). Twenty-five mature ipiSSPs
207 (~35.7%) possess one or more NXS/T motifs (Information S1).

208 Basic local alignment search tool (BLAST) homology searches against publicly
209 available sequence databases at the National Center for Biotechnology Information (NCBI)
210 and the Joint Genome Institute (JGI) revealed that 14 of the 70 apoplasmic ipiSSPs are novel
211 (20%), while 47 (~67.1%) have homology to proteins of unknown function (Tables 1 and
212 S1). The nine remaining ipiSSPs (~12.9%) have known or predicted functional domains, or
213 have homology to proteins with characterized biological functions. These are: Avr4
214 (CBM_14 domain; PF01607); Ecp2-1 (Hce2 domain; PF14856); Ecp6 (three LysM domains;
215 PF01476); CfPhiA-1 and CfPhiA-2 (phialide proteins); CfCE55 (class II hydrophobin
216 [Fig. 1]); CfCE60 (GPI-anchored superfamily domain; PF10342); CfCE61 (cerato-platanin
217 protein; PF07249); and CfCE69 (hydrophobic surface-binding protein A [HsbA] domain;
218 PF12296) (Tables 1 and S1). BLASTp homology searches and Cys spacing comparisons also
219 revealed that 23 ipiSSPs are related to each other at the amino acid level. These are: Avr9 and
220 CfCE67; CfCE4 and CfCE16; CfCE5, CfCE25 and CfCE65; CfCE9 and CfCE49; CfCE13
221 and CfCE63; CfCE14 and CfCE31; CfCE24, CfCE56, CfCE58 and CfCE72 (N-terminal
222 region [NTR; residues 21–113]; CfCE30 and CfCE70 (IgE-binding proteins); CfPhiA-1 and
223 CfPhiA-2; and Ecp4, Ecp7 and CfCE72 (C-terminal region [CTR; residues 158–266])
224 (Tables 1 and S1).

225 As 61 of the 70 apoplasmic ipiSSPs (~87.1%) are novel or have homology to proteins
226 of unknown function, 10 three-dimensional protein structure prediction servers were
227 employed to infer possible structural relationships between these and proteins of
228 characterized tertiary structure and/or function present in the Research Collaboratory for
229 Structural Bioinformatics Protein Data Bank (RCSB PDB). Three ipiSSPs (CfCE5, CfCE25
230 and CfCE65) were consistently predicted to have structural homology to Alt a 1 (RCSB PDB
231 IDs: 3V0R and 4AUD), an allergen protein with a β -barrel fold (Chruszcz et al., 2012) from
232 the broad host-range Dothideomycete fungal plant pathogen/saprophyte *Alternaria alternata*
233 (Table S2). Four ipiSSPs (Ecp4, Ecp7, CfCE44 and CfCE72 [CTR]) were consistently
234 predicted to have structural homology to proteins with a β/γ -crystallin fold, including the
235 plant antimicrobial protein MiAMP1 from *Macadamia integrifolia* (ID: 1C01) (McManus et
236 al., 1999), and the yeast killer toxin WmKT from *Williopsis mrakii* (ID: 1WKT) (Antuch et
237 al., 1996) (Table S2). A further three ipiSSPs (CfCE24, CfCE56 and CfCE58) were

238 consistently predicted to have structural homology to the α and/or β subunit of KP6 (IDs:
239 1KP6 and 4GVB), a virus-encoded antifungal killer toxin with an α/β -sandwich fold secreted
240 by the fungal corn smut pathogen *Ustilago maydis* (Allen et al., 2013a; Li et al., 1999) (Table
241 S2). Notably, the NTR of CfCE72 was found to share sequence homology with CfCE24,
242 CfCE56 and CfCE58 (Fig. S1A), suggesting that it too adopts a KP6-like fold. The NTR and
243 CTR of CfCE72 are separated by a putative kexin protease cleavage site (Fig. S1A and
244 Information S1).

245 Hidden Markov model (HMM)–HMM alignments generated between CfCE5 and Alt
246 a 1, Ecp4 and MiAMP1, as well as CfCE58 and KP6 β (i.e. as part of the HHPred server
247 output [Söding et al., 2005]), are shown in Fig. S2. In addition to conserved elements of
248 secondary structure, all three alignments revealed conserved Cys residues. For CfCE5 and Alt
249 a 1, two conserved Cys residues at positions 50 and 65 (mature proteins), which are also
250 present in CfCE25 and CfCE65, were identified (Figs S1B and S2A). In Alt a 1, these Cys
251 residues are known to form an intramolecular disulphide bond (Chruszcz et al., 2012).
252 Inspection of the predicted CfCE5 tertiary structure, which was modelled using Alt a 1 as a
253 template in HHpred (MODELLER) (Söding et al., 2005; Webb and Sali, 2002) and RaptorX
254 (Källberg et al., 2012), suggests that the conserved Cys50/Cys65 pair forms an intramolecular
255 disulphide bond (Fig. S3A). Furthermore, the predicted structure suggests that the two
256 remaining Cys residues, Cys24 and Cys29, which are absent from Alt a 1 (Fig. S2A), may
257 also form an intramolecular disulphide bond, given that they are located in close proximity to
258 each other (Fig. S3A). This bond, however, would be located in a different location to the
259 second intramolecular disulphide bond of Alt a 1 (Cys104–Cys116) (Fig. S3A) (Chruszcz et
260 al., 2012).

261 Five of the six Cys residues present in Ecp4 and MiAMP1 were found to be
262 conserved (Fig. S2B). In MiAMP1, all six Cys residues are known to form intramolecular
263 disulphide bonds (Cys11–Cys65, Cys21–Cys76 and Cys23–Cys49) (McManus et al., 1999).
264 Inspection of the predicted Ecp4 structure, which was modelled using MiAMP1 as a
265 template, suggests that two of the conserved Cys pairs, Cys16/Cys84 and Cys35/Cys67, form
266 intramolecular disulphide bonds (Fig. S3B). Although not conserved, the sixth Cys residue in
267 Ecp4, Cys57, still appears to be located in a favourable position for disulphide bond
268 formation with Cys99 (Fig. S3B). All six Cys residues in Ecp4 are conserved across Ecp7
269 and CfCE72 (CTR), although the latter has an additional pair of Cys residues (Fig. S1C).

270 For CfCE58 and KP6 β , six conserved Cys residues, which are also present in CfCE24
271 and CfCE56, were identified (Figs S1A and S2C). In KP6 β , these six Cys residues are known

272 to form three intramolecular disulphide bonds (Cys9–Cys74, Cys11–Cys64 and Cys29–
273 Cys46) (Allen et al., 2013a). The predicted CfCE58 structure, which was modelled using
274 KP6 β as a template, suggests that the three conserved Cys pairs (Cys7/Cys76, Cys9/Cys66
275 and Cys26/Cys47) form intramolecular disulphide bonds (Fig. S3C). Both CfCE56 and
276 CfCE58 possess an additional set of Cys residues (Cys1 and Cys60) (Fig. S1A). Cys1 of
277 CfCE58 is located at the extreme N-terminus, which, if flexible, would be expected to make
278 contact with Cys60 located at the base of one of the predicted α -helices (Fig. S3C).

279

280 **Most apoplastic ipiSSPs of *C. fulvum* lack an ortholog in *Dothistroma septosporum*.**

281 Of the fungi for which a genome sequence is so far available, *D. septosporum* is the most
282 closely related to *C. fulvum* (de Wit et al., 2012). Reciprocal BLASTp and tBLASTn searches
283 were used to determine whether the predicted *D. septosporum* protein catalogue and genome
284 (de Wit et al., 2012) carry homologs of the 70 *C. fulvum* apoplastic ipiSSPs and their
285 encoding genes, respectively. For 43 of the 70 ipiSSPs, no homologs were identified (Table
286 S1). A further four showed limited homology to *D. septosporum* genes, while five others had
287 homology to pseudogenes (Table S1). The remaining 18 ipiSSPs had likely orthologs in
288 *D. septosporum*. However, of these, only 11 were up-regulated during infection of pine
289 (Table S1) (Bradshaw et al., 2016). More specifically, these are the likely orthologs of
290 Ecp2-1, Ecp6, CfCE33, the three Alt a 1 allergen-like proteins (CfCE5, CfCE25 and
291 CfCE65), CfCE16, the cerato-platanin (CfCE61), the phialide protein CfPhiA-2 (CfCE53),
292 CfCE74 and CfCE77 (Table S1). Genes encoding SSPs with a potential β/γ -crystallin or
293 KP6-like fold were absent, pseudogenized, or not expressed during colonization of pine
294 (Table S1).

295

296 **Nine apoplastic ipiSSPs of *C. fulvum* trigger an HR in specific accessions of tomato.**

297 To identify new sources of resistance against *C. fulvum*, wild accessions of tomato were
298 screened for their ability to recognize apoplastic ipiSSPs using the PVX-based transient
299 expression system (Hammond-Kosack et al., 1995; Takken et al., 2000). In this experiment,
300 recombinant viruses were delivered through agroinfection for local (toothpick wounding) or
301 systemic (cotyledon infiltration) expression of ipiSSPs in tomato, with the pathogenesis-
302 related 1A (PR1A) signal peptide of tobacco (*Nicotiana tabacum*) used to direct secretion of
303 these proteins into the tomato leaf apoplast. Plants that showed a chlorotic or necrotic HR
304 were deemed to have recognized an ipiSSP as an IP.

305 As a starting point, 25 predominantly wild accessions of tomato (Table S3) were
306 screened for their ability to recognize Ecp7 and/or one or more of 40 CfCEs (Table S1) using
307 the PVX agroinfection method based on toothpick wounding (Luderer et al., 2002a; Takken
308 et al., 2000). This set of 40 CfCEs primarily comprises those with the highest level of
309 expression *in planta*, as based on pre-existing RNA-Seq data shown in Table S1. A fully
310 expanded leaf from 1–3 representative plants of each accession was inoculated via toothpick
311 wounding on each side of the main vein, and the presence or absence of an HR was scored at
312 10 dpi. At the same time, *S. lycopersicum* cv. MM-Cf-0 (no Cf immune receptors; Tigchelaar,
313 1984) was screened to determine whether Ecp7 or any of the CfCEs trigger a non-specific
314 HR. Likewise, accessions carrying only the *Cf-1*, *Cf-3*, *Cf-6*, *Cf-9B*, *Cf-11* or *Cf-Ecp3*
315 immune receptor gene (Table S3) were screened to determine whether Ecp7 or any of the
316 CfCEs represent one of the yet unknown IP effectors Avr1, Avr3, Avr6, Avr9B, Avr11 or
317 Ecp3. As positive controls, *S. lycopersicum* cv. MM-Cf-5, which carries only the *Cf-5*
318 immune receptor (Tigchelaar, 1984), as well as the landrace accession CGN 18399
319 (*S. lycopersicum* var. *cerasiforme*), from which the *Cf-5* gene was originally identified (Kerr
320 et al., 1971), were screened for their ability to recognise the IP effector Avr5 (Mesarich et al.,
321 2014). Empty vector was used as a negative control to confirm that PVX alone does not
322 trigger a non-specific HR. For the purpose of this experiment, recognition of Ecp7 or a CfCE
323 was deemed to have occurred if an HR was triggered at one or both of the toothpick
324 wounding sites on a given tomato leaf.

325 As expected, the empty vector (negative control) failed to trigger an HR in any tomato
326 accession tested, while Avr5 (positive control) was recognized by only MM-Cf-5 and CGN
327 18399 (Fig. S4), indicating that the PVX agroinfection method is functional, and that no other
328 accessions carry the *Cf-5* immune receptor gene. Ten of the 40 CfCEs (CfCE6, CfCE9,
329 CfCE14, CfCE18, CfCE19, CfCE26, CfCE33, CfCE48, CfCE55 and CfCE59) were
330 recognized by one to eight predominantly wild accessions of tomato, with HRs ranging from
331 weak chlorosis to strong necrosis (Fig. S4). Furthermore, 15 of the 25 accessions recognized
332 between one and four of the 10 CfCEs (Fig. S4). Importantly, none of the 10 CfCEs triggered
333 an HR in MM-Cf-0, suggesting that the observed responses were specific to the accessions
334 tested (Fig. S4). None of the accessions carrying the *Cf-1*, *Cf-3*, *Cf-6*, *Cf-9B*, *Cf-11* or
335 *Cf-Ecp3* immune receptor gene recognized Ecp7 or any of the CfCEs, indicating that these
336 ipiSSPs do not represent the IP effectors Avr1, Avr3, Avr6, Avr9B, Avr11 or Ecp3. A
337 schematic of the 10 HR-eliciting CfCEs is shown in Fig. 1.

338 To further confirm recognition of the 10 CfCEs, each was screened for its ability to
339 trigger a systemic HR in the same responding tomato accessions using the PVX agroinfection
340 method based on cotyledon infiltration (Mesarich et al., 2014). Here, both cotyledons of five
341 independent plants were infiltrated, and the presence or absence of an HR was scored at 21
342 dpi. Consistent with the agroinfection assay based on toothpick wounding, the empty vector
343 (negative control) did not trigger an HR in any accession tested (Figs 2 and S5). Similarly,
344 none of the CfCEs triggered an HR in MM-Cf-0 (Fig. S6). For CfCE6, CfCE26, CfCE48 and
345 CfCE55, recognition could be confirmed across all responding accessions identified in the
346 toothpick wounding agroinfection assay (Figs 2 and S7–S8). Recognition could also be
347 confirmed across most, but not all, previously identified accessions for CfCE9, CfCE14,
348 CfCE18, CfCE33 and CfCE59 (Figs 2 and S9–S13). Indeed, CfCE9, CfCE14, CfCE18 and
349 CfCE33 only failed to trigger an HR in accessions CGN 15392 (*Solanum arcanum*) (Fig. S9),
350 CGN 14356 (*Solanum peruvianum*) (Fig. S10), CGN 14357 (*Solanum corneliomuelleri*)
351 (Fig. S11) and CGN 14353 (*S. pimpinellifolium*) (Fig. S12), respectively, while CfCE59 only
352 failed to trigger an HR in CGN 14353 and CGN 24034 (*S. pimpinellifolium*) (Fig. S13). In
353 some cases, the recognition of a CfCE could not be observed across all five plants of a given
354 accession representing *S. corneliomuelleri* (CGN 14357 and CGN 15793), *S. peruvianum*
355 (CGN 14355, CGN 14356 and CGN 24192) and *S. pimpinellifolium* (CGN 15946) (Figs 2,
356 S7, S9, S11 and S13). In all responding accessions, the systemic HR involved weak to strong
357 necrosis, and was typically associated with moderate to severe stunting (Figs 2, S7–S11 and
358 S13–S14). The recognition of only one CfCE, CfCE19, could not be confirmed (CGN 24034;
359 Fig. S15).

360

361 **Tomato accessions that recognize apoplastic ipiSSPs are resistant to *C. fulvum*.**

362 To determine whether the accessions of tomato that recognize apoplastic ipiSSPs are resistant
363 to *C. fulvum*, each, along with *S. lycopersicum* cv. MM-Cf-0, was inoculated with strain
364 2.4.5.9.11 IPO of this fungus, and symptoms were inspected on leaves from three
365 independent plants at 14 dpi. Strain 2.4.5.9.11 IPO carries genes corresponding to all nine
366 HR-eliciting CfCEs (see below), but lacks a functional copy of the previously cloned *Avr2*,
367 *Avr4*, *Avr4E*, *Avr5* and *Avr9 IP* effector genes (Mesarich et al., 2014; Stergiopoulos et al.,
368 2007). As expected, *S. lycopersicum* cv. MM-Cf-0 was susceptible to 2.4.5.9.11 IPO
369 (Fig. S16). In contrast, all other tomato accessions tested were resistant to this strain
370 (Fig. S16). For accessions CGN 14474 (*S. lycopersicum*) and CGN 15820 (*S. lycopersicum* x
371 *cheesmaniae*), this resistance was observed across only two of the three independent plants

372 (Fig. S16). While resistant to *C. fulvum*, we cannot exclude the possibility that the set of
373 resistant tomato accessions carries one or more of, for example, the *Cf* immune receptor
374 genes *Cf-1*, *Cf-3*, *Cf-6*, *Cf-9B*, *Cf-Ecp1*, *Cf-Ecp2-1*, *Cf-Ecp3*, *Cf-Ecp4*, *Cf-Ecp5* and *Cf-Ecp6*.

375 As CfCE6, CfCE9, CfCE14, CfCE18, CfCE26, CfCE33, CfCE55, CfCE59 and
376 CfCE48 are present in IWF samples from compatible *C. fulvum*–tomato interactions, and
377 because these proteins triggered an HR using both PVX agroinfection methods, only these
378 apoplastic ipiSSPs were pursued further. From this point forward, CfCE6, CfCE9, CfCE14,
379 CfCE18, CfCE26, CfCE33, CfCE55, CfCE59 and CfCE48 will be referred to as Ecp9-1,
380 Ecp10-1, Ecp11-1, Ecp12, Ecp13, Ecp14-1, Ecp15 and Ecp16, respectively.

381

382 **Seven HR-eliciting Ecps have one or more homologs in other fungal species, while three**
383 **HR-eliciting Ecps have one or more paralogs in *C. fulvum*.**

384 To identify homologs of the HR-eliciting Ecps in other fungi, each was screened against the
385 publicly available protein sequence databases at NCBI and JGI using BLASTp. Additionally,
386 in those cases where no protein homolog could be identified, Ecps were screened against the
387 collection of fungal genome sequences present at JGI using tBLASTn (i.e. to identify
388 homologs without a gene prediction). With the exception of Ecp8 and Ecp16, homologs of all
389 HR-eliciting Ecps were identified in other fungal species. For Ecp9-1, homologs were
390 identified in the Dothideomycetes *Pseudocercospora fijiensis* (black sigatoka disease of
391 banana), *Septoria musiva* and *Septoria populicola* (leaf spot and canker diseases of poplar),
392 *Teratosphaeria nubilosa* (leaf spot of *Eucalyptus* spp.) and *Zasmidium cellare* (saprobic wine
393 cellar fungus), as well as eight Sordariomycete species (Fig. S17). Eight paralogs of Ecp9-1
394 were found to be encoded by the genome of *C. fulvum* strain 0WU (Ecp9-2–Ecp9-9)
395 (Fig. S18A), with one clear pseudogene also identified (*Ecp9-10*; result not shown). A similar
396 expansion was found in the Sordariomycete *Claviceps purpurea* (ergot disease of cereals)
397 (Fig. S17).

398 Homologs of Ecp10-1 were identified in the Dothideomycetes *Pseudocercospora*
399 *eumusae* and *Pseudocercospora musae* (eumusae leaf spot and yellow sigatoka disease of
400 banana, respectively), *A. alternata*, *S. musiva*, *S. populicola*, *T. nubilosa* and *Z. cellare*, as
401 well as *Zymoseptoria ardabiliae*, *Zymoseptoria pseudotritici* and *Zymoseptoria tritici* (leaf
402 blotch diseases of grasses), *Venturia inaequalis* and *Venturia pirina* (apple and pear scab
403 disease, respectively), *Clathrospora elyanae* (found growing on curved sedge), *Cochliobolus*
404 *sativus* and *Cochliobolus victoriae* (cereal pathogens), *Pyrenophora teres* f. *teres* (net blotch
405 disease of barley), *Pyrenophora tritici-repentis* (tan spot disease of wheat) and *Setosphaeria*

406 *turcica* (northern corn leaf blight disease) (Fig. S19 and Information S2). Homologs of
407 Ecp10-1 were also identified in several Sordariomycete fungi (Fig. S19 and Information S2).
408 Interestingly, Ecp10-1 homologs were found to be massively expanded in *V. inaequalis* and
409 *V. pirina* (Information S2), which is not uncommon for effector candidates from these fungi
410 (Deng et al., 2017). Smaller expansions were also identified in other fungal plant pathogens
411 (Information S2). Two paralogs of Ecp10-1 (Ecp10-2 and Ecp10-3) were found to be
412 encoded by the genome of *C. fulvum* strain 0WU (Fig. S18B).

413 Homologs of the remaining Ecps were only identified in Dothideomycete fungi.
414 Ecp11-1 was found to have homology to AvrLm3 and AvrLmJ1, two avirulence effector
415 proteins from *Leptosphaeria maculans* (blackleg disease of Brassica species) (Plissonneau et
416 al., 2016; van de Wouw et al., 2014), as well as two proteins from *Z. ardabiliae* (Figs 3 and
417 S20). A single pseudogene of *Ecp11-1* (*Ecp11-2*) was also identified in the genome of
418 *C. fulvum* strain 0WU (*result not shown*). Ecp12 was found to have multiple homologs in
419 *S. musiva* and *S. populicola*, with the homologous Cys-rich domain occurring once, or as two
420 or three tandem repeats (Fig. S21), as has been found for several other effectors from plant-
421 associated organisms (Mesarich et al., 2015). Homologs of Ecp13 were identified in
422 *D. septosporum*, *P. fijiensis*, *S. musiva* and *Cercospora zae-maydis* (grey leaf spot disease of
423 maize) (Fig. S22), while homologs of Ecp14-1 were found in *C. zae-maydis*,
424 *D. septosporum*, *P. eumusae*, *P. fijiensis*, *P. musae*, *S. musiva*, *S. populicola*, *T. nubilosa*,
425 *Trypethelium eluteriae* (lichen-forming fungus), *Z. ardabiliae*, *Zymoseptoria brevis* (leaf
426 blotch disease of barley), *Z. pseudotritici*, *Z. tritici* and *Z. cellare*, with most, including
427 *C. fulvum*, possessing a paralog (Figs S18C and S23). A single pseudogene of *Ecp14-1*
428 (*Ecp14-3*) was identified in the genome of *C. fulvum* strain 0WU (*result not shown*). For
429 Ecp15, homologs were found in *P. fijiensis*, *P. musae* and *Z. ardabiliae* (Fig. S24).

430

431 **Genes encoding HR-eliciting Ecps are induced *in planta*.**

432 RNA-Seq fragments per kilobase (kb) of exon per million fragments mapped (FPKM) values
433 suggested that all genes encoding an HR-eliciting Ecp of *C. fulvum*, like those encoding all
434 previously identified IP effectors of this fungus (Mesarich et al., 2014), are induced during
435 infection of susceptible tomato, when compared to expression during growth *in vitro* in PDB
436 or Gamborg B5 liquid media (Table S1). To confirm this expression profile, a reverse-
437 transcription quantitative real-time polymerase chain reaction (RT-qrtPCR) experiment was
438 performed. Indeed, all genes encoding an HR-eliciting Ecp were found to be induced during

439 infection of susceptible tomato, when compared to expression during growth *in vitro* in PDB
440 or Gamborg B5 liquid media (Fig. 4).

441

442 **Most genes encoding an HR-eliciting Ecp are associated with repetitive elements.**

443 It is common for *C. fulvum* effector genes to be flanked by a mosaic of repetitive elements in
444 the genome of strain 0WU (de Wit et al., 2012; Mesarich et al., 2014). It has been proposed
445 that these elements may assist in the deletion of *IP* effector genes following *Cf* immune
446 receptor-imposed selection pressure (Mesarich et al., 2014). To determine whether repetitive
447 elements also flank genes encoding the HR-eliciting Ecps, the genome scaffolds harbouring
448 each of these genes was screened for repetitive sequence across the *C. fulvum* 0WU genome
449 using BLASTn. Six of the nine *Ecp* genes (*Ecp8*, *Ecp9-1*, *Ecp10-1*, *Ecp11-1*, *Ecp12* and
450 *Ecp15*) were found to be associated with repetitive elements at both their 5' and 3' flanks
451 (Fig. S25). Furthermore, the same six genes were found to reside on small genome scaffolds
452 of less than 35 kb in length (Table S4). The latter suggests that the scaffolds harbouring these
453 genes are surrounded by even larger flanking repetitive elements, with these elements
454 anticipated to have hampered a larger scaffold assembly (Wit et al., 2012). The 5' end of
455 *Ecp16* is closely associated with repetitive elements, and is present at the 5' end of an ~55-kb
456 scaffold (Fig. S25). Likewise, *Ecp13* is located at the 3' end of an ~57-kb scaffold, suggesting
457 the presence of 3' repeats (Fig. S25). In contrast to the *Ecp* genes mentioned above, *Ecp14-1*
458 is not surrounded by repetitive elements (Fig. S25).

459

460 **Genes encoding an HR-eliciting Ecp exhibit limited allelic variation between strains.**

461 It is common for genes encoding *C. fulvum* *IP* effectors to exhibit allelic variation between
462 strains, which is often brought about by selection pressure to avoid recognition by
463 corresponding *Cf* immune receptors (Iida et al., 2015; Joosten et al., 1994; Luderer et al.,
464 2002a; Mesarich et al., 2014; Westerink et al., 2004). To assess the level of allelic variation
465 across genes encoding the HR-eliciting Ecps, each was amplified by PCR from 10 different
466 *C. fulvum* strains (Table S5), sequenced, and compared to the corresponding sequence from
467 strain 0WU. All nine *Ecp* genes could be amplified by PCR from genomic DNA samples
468 representing the 10 *C. fulvum* strains. Of the nine genes, four, namely *Ecp9-1*, *Ecp10-1*,
469 *Ecp13* and *Ecp15*, exhibited no allelic variation between strains. For *Ecp8* and *Ecp16*, allelic
470 variation was observed; however, this variation did not result in a change of amino acid
471 sequence. More specifically, in six strains (2.4, 2.4.5, 2.5, 2.9, 4 and 7320), *Ecp8* had a single

472 synonymous CCC→CCT substitution at position 153, while in four strains (2.4, 2.4.5, 2.5
473 and 4), *Ecp16* had a trinucleotide insertion (CTT) at position 234 in an intron (Fig. 5). For
474 each of the remaining three genes, a single non-synonymous substitution was identified: a
475 TTT→GTT (Phe119Val) change at position 355 in *Ecp11-1* of strain 2.9; a GGG→AGG
476 (Gly124Arg) change at position 484 in *Ecp12* of strains 2.9 and 7320; and an AAG→GAG
477 (Lys148Glu) change at position 501 in *Ecp14-1* of strains 2.4, 2.4.5, 2.4.5.9.11 IPO, 2.4.9.11,
478 2.5, 2.9 and 4 (Fig. 5). A G→T mutation at position 386 of the *Ecp14-1* intron in strains 2.4,
479 2.4.5, 2.4.5.9.11 IPO, 2.4.9.11, 2.5 and 4, as well as a synonymous GGG→GGA substitution
480 at position 452 in *Ecp14-1* of strains 2.4, 2.4.5, 2.4.5.9.11 IPO, 2.4.9.11, 2.5, 2.9 and 4, were
481 also identified (Fig. 5). It is not yet known whether the non-synonymous substitutions
482 identified in *Ecp11-1*, *Ecp12* and *Ecp14-1* allow *C. fulvum* to overcome resistance mediated
483 by the putative *Cf-Ecp11-1*, *Cf-Ecp12* and *Cf-Ecp14-1* immune receptor genes, respectively.

484

485 DISCUSSION

486 Leaf mould disease of tomato, caused by the fungal pathogen *C. fulvum*, is a re-emerging
487 problem worldwide. This re-emergence is due to intensive year-round cultivation of resistant
488 tomato cultivars, which have selected for natural strains of this fungus capable of
489 overcoming, for example, one or more of all cloned *Cf* immune receptor genes (Hubbeling,
490 1978; Iida et al., 2015; Laterrot, 1986; Li et al., 2015). To combat these strains, new *Cf*
491 immune receptor genes need to be identified. Wild tomato is a rich source of resistance
492 against *C. fulvum* (Kruijt et al., 2005; Laugé et al., 1998, 2000; van der Hoorn et al., 2001b).
493 In this study, an effectoromics approach (Domazakis et al., 2017; Du and Vleeshouwers,
494 2014) based on apoplastic ipiSSPs of *C. fulvum* was used to identify wild accessions of
495 tomato carrying new *Cf* immune receptor genes.

496 As a starting point for this approach, proteomics and transcriptome sequencing were
497 used to identify fungal SSPs most relevant to the *C. fulvum*–tomato interaction. Altogether,
498 70 apoplastic ipiSSPs, made up of all 11 characterized SSP effectors of this fungus (Bolton et
499 al., 2008; Joosten et al., 1994; Laugé et al., 2000; Luderer et al., 2002a; Mesarich et al., 2014;
500 van den Ackerveken et al., 1993; van Kan et al., 1991; Westerink et al., 2004), as well as 32
501 previously described (Mesarich et al., 2014) and 27 new CfCEs, were identified in IWF
502 samples from compatible *C. fulvum*–*S. lycopersicum* cv. H-Cf-0 interactions. Strikingly, all
503 but eight of these ipiSSPs are Cys-rich and possess an even number of Cys residues.
504 Consistent with that shown for Avr4, Avr9, Ecp1, Ecp2-1, Ecp5 and Ecp6, it is likely that
505 many of these Cys residues form intramolecular disulphide bonds required for stability and

506 function in the protease-rich leaf apoplast of tomato (Joosten et al., 1997; Luderer et al.,
507 2002b; Sánchez-Vallet et al., 2013; van den Burg et al., 2003; van den Hooven et al., 2001).

508 Following signal peptide cleavage, several of the ipiSSPs likely undergo further post-
509 translational processing in the ER–Golgi secretory pathway. Twenty-five ipiSSPs possess one
510 or more NXS/T motifs following their predicted signal peptide cleavage site, suggesting that
511 they undergo N-linked glycosylation. This glycosylation may be required for ipiSSP folding,
512 structure, stability, solubility, oligomerization, or function (Helenius and Aebi, 2001). A
513 further six ipiSSPs possess a putative N-terminal kexin protease cleavage site (LXXK/PR
514 motif), suggesting that they have a propeptide domain. It is possible that these ipiSSPs are
515 synthesized as inactive precursors, and that, for biological activity, their propeptide domain
516 must be removed by a kexin protease (Rockwell et al., 2002).

517 BLAST homology searches revealed that, in addition to Avr4 (single CBM_14
518 domain; PF01607) (van den Burg et al., 2003), Ecp2-1 (single Hce2 domain; PF14856)
519 (Stergiopoulos et al., 2012), Ecp6 (three LysM domains; PF01476) (Bolton et al., 2008) and
520 CfPhiA-1 (phialide protein) (Bolton et al., 2008), five other ipiSSPs, specifically CfPhiA-2,
521 CfCE60, CfCE61, CfCE69 and Ecp14-1, possess a known functional domain or have
522 homology to proteins with a characterized biological function. Of these, CfPhiA-2 has
523 homology to CfPhiA-1 and other phialide proteins from Ascomycete fungi. To date, the best
524 characterized of these homologs is PhiA from *Aspergillus nidulans*, which localizes to the
525 cell wall of phialides and conidia (Melin et al., 2003). PhiA plays an essential role in the
526 development of phialides, which are sporogenous cells that produce and release conidia
527 through a specialized apical budding process (Melin et al., 2003).

528 CfCE60 has a GPI-anchored superfamily domain (PF10342), but is not predicted to
529 possess a GPI anchor modification site. Little functional information is available for secreted
530 proteins with this domain. However, in the Basidiomycete fungus *Lentinula edodes* (shiitake
531 mushroom), the PF10342 domain-containing protein Le.DRMIP, which also possesses a
532 mitochondrial targeting signal peptide and transmembrane domain, interacts with the
533 developmentally regulated MAP kinase Le.MAPK. Both proteins have been proposed to play
534 a role in cell differentiation during fruiting body development (Szeto et al., 2007).

535 CfCE61 is a member of the cerato-platanins (PF07249), a class of proteins ubiquitous
536 to filamentous fungi that adopts a double $\Psi\beta$ -barrel fold similar to domain one of expansins
537 (Chen et al., 2013; de Oliveira et al., 2011). Cerato-platanins are predominantly secreted,
538 although several also localize to the cell wall of ascospores, conidia and hyphae (e.g. Boddi et
539 al., 2004; Pazzagli et al., 1999). Cerato-platanins are postulated to carry out multiple

540 biological functions related to fungal growth and development, as well as to plant–fungus
541 interactions. Notably, cerato-platanins bind chitin, but not cellulose (Bacelli et al., 2014; de
542 O. Barsottini et al., 2013; Frischmann et al., 2013), yet several members have expansin-like
543 activity *in vitro*, loosening cellulosic materials (Bacelli et al., 2014; de O. Barsottini et al.,
544 2013). It has thus been hypothesized that cerato-platanins may function as expansins required
545 for fungal cell wall remodelling and enlargement, possibly by disrupting non-covalent
546 interactions between β -glucan or chitin molecules (de Oliveira et al., 2011). Epl1, a surface-
547 active cerato-platanin from the biocontrol agent *Trichoderma atroviride*, self-assembles at the
548 air/water interface, forming protein films that increase the polarity of solutions and surfaces
549 (Frischmann et al., 2013). This suggests an additional role for cerato-platanins in increasing
550 the wettability of hyphae, enabling them to grow in aqueous environments, or in protecting
551 them from desiccation (Frischmann et al., 2013).

552 Deletion of the gene encoding MSP1, a cerato-platanin from the rice blast pathogen
553 *Magnaporthe oryzae*, resulted in reduced virulence *in planta*, suggesting that certain
554 members of this protein class function as effectors (Jeong et al., 2007). In line with this,
555 preliminary studies have suggested that MpCP5, a cerato-platanin from *Moniliophthora*
556 *perniciosa* (witches' broom disease of cocoa) may, like Ecp6, perturb chitin-triggered
557 immunity (de O. Barsottini et al., 2013), while cerato-platanins from *Fusarium graminearum*
558 (cereal head blight disease) may, like Avr4, protect fungal cell wall polysaccharides from
559 enzymatic digestion by chitinases and β -1,3-glucanases (Quarantin et al., 2016). Some cerato-
560 platanins are also well-known IPs that trigger a non-specific HR upon recognition by
561 corresponding host immune receptors (e.g. Frías et al., 2011, 2014). This, however, does not
562 appear to be the case for CfCE61, which failed to trigger an HR in tomato.

563 CfCE69 contains an HsbA domain (PF12296), which was originally identified in the
564 HsbA protein from *Aspergillus oryzae* (Ohtaki et al., 2006), a filamentous fungus commonly
565 used in the fermentation industry. In culture, HsbA is secreted in the presence of the
566 hydrophobic polymer polybutylene succinate-*co*-adipate (PBSA). HsbA binds PBSA, and in
567 doing so, recruits CutL1, a polyesterase/cutinase, for its degradation (Ohtaki et al., 2006).

568 Ecp14-1 is a member of the hydrophobins, a fungal-specific class of surface-active
569 proteins (Wessels, 1994). With the exception of eight conserved Cys residues, which form
570 four intramolecular disulphide bonds, hydrophobins share limited sequence similarity
571 (Wessels, 1994). Ecp14-1 is the twelfth hydrophobin, and sixth class II hydrophobin, to be
572 identified from *C. fulvum* (de Wit et al., 2012; Nielsen et al., 2001; Segers et al., 1999; Spanu,
573 1997). It is also the first hydrophobin to be identified from this fungus that is exclusively

574 expressed *in planta* (Fig. 4). Hydrophobins are initially secreted in a soluble form, but then
575 spontaneously localize to hydrophilic:hydrophobic interfaces, where they assemble into
576 insoluble, amphipathic layers (Sunde et al., 2017). Hydrophobins are typically found on the
577 outer cell wall surface of aerial hyphae, fruiting bodies and spores, where they reduce
578 wettability, or significantly decrease the surface tension of moist environments, allowing
579 these structures to grow in the air (Wösten et al., 1999). Other roles related to surface
580 perception, attachment to hydrophobic surfaces, and plant colonization have also been shown
581 (Kim et al., 2005; Talbot et al., 1993, 1996). So far, the function of only one *C. fulvum*
582 hydrophobin, HCf-1 (Class I), has been determined. HCf-1 is required for efficient water-
583 mediated dispersal of conidia (Whiteford and Spanu, 2001).

584 Unlike those described above, BLAST homology searches revealed that most
585 *C. fulvum* ipiSSPs (61 of 70) are novel or have homology to proteins of unknown function.
586 Remarkably, 10 of these ipiSSPs were consistently predicted to have structural homology to
587 proteins present in the RCSB PDB. Of these, CfCE5, CfCE25 and CfCE65 were predicted to
588 be structurally homologous to Alt a 1 from *A. alternata*, which adopts a β -barrel fold unique
589 to fungi (Chruszcz et al., 2012; de Vouge et al., 1996). Recent studies have shown that Alt a 1
590 is an effector protein with multiple roles in promoting host colonization. Initially, Alt a 1
591 localizes to the cytoplasm and cell wall of *A. alternata* spores (Garrido-Arandia et al., 2016b;
592 Gómez-Casado et al., 2014). In humid settings, these spores then germinate, and in
593 environments with a pH range of between 5.0 and 6.5, Alt a 1 is released as a tetramer
594 carrying a fungal methoxyflavonol ligand similar to the plant flavonol quercetin (Garrido-
595 Arandia et al., 2016a, b). In the same pH range, which is typical of apoplastic environments,
596 this complex breaks down, releasing Alt a 1 monomers and the flavonol ligand (Garrido-
597 Arandia et al., 2016a, b). The Alt a 1 monomers then function as competitive inhibitors of
598 extracellular plant defence proteins belonging to the pathogenesis-related 5-thaumatin-like
599 protein (PR5-TLP) family (Gómez-Casado et al., 2014), while the flavonol ligand detoxifies
600 reactive oxygen species (ROS) (Garrido-Arandia et al., 2016b). It remains to be determined
601 whether CfCE5, CfCE25 and CfCE65 function in a similar manner during colonization of the
602 tomato leaf apoplast by *C. fulvum*. Interestingly, homologs of CfCE5, CfCE25 and CfCE65
603 are encoded by the genome of *D. septosporum* (de Wit et al., 2012), and these genes are up-
604 regulated during the infection of pine (Bradshaw et al., 2016). This suggests that the Alt a 1
605 allergen-like proteins, together with the cerato-platanin, Ecp2-1, Ecp6 and Ecp14-1, which
606 are also ipiSSPs of *D. septosporum* (Bradshaw et al., 2016; de Wit et al., 2012), are core

607 effectors that play important roles in the virulence of both pathogens. These *D. septosporum*
608 ipiSSPs have been shortlisted for future functional characterization (Hunziker et al., 2016).

609 Four of the nine ipiSSPs, specifically Ecp4, Ecp7, CfCE72 (CTR) and CfCE44, were
610 predicted to be structurally homologous to proteins with a β/γ -crystallin fold. This fold,
611 which typically comprises two four-stranded, anti-parallel Greek key motifs, was originally
612 identified in structural proteins responsible for maintaining the refractive index and
613 transparency of the vertebrate eye lens (Blundell et al., 1981; Wistow et al., 1983). However,
614 this fold is now known to occur in a variety of functionally diverse proteins representing all
615 major taxonomic groups of organisms (Kappé et al., 2010; Mishra et al., 2014). A key feature
616 of this fold in many microbial members is a double clamp N/DN/DXXS/TS Ca²⁺-binding
617 motif required for structure and/or function (Srivastava et al., 2014). This motif, however, is
618 not present in Ecp4, Ecp7, CfCE72 (CTR) or CfCE44.

619 Strikingly, Ecp4, Ecp7 and CfCE72 (CTR) share a Cys spacing profile with
620 MiAMP1, a plant antimicrobial protein with a β/γ -crystallin fold from nut kernels of *M.*
621 *integrifolia* (Marcus et al., 1997; McManus et al., 1999). Purified MiAMP1 exhibits broad
622 spectrum inhibitory activity against several plant-pathogenic fungi, oomycetes and gram-
623 positive bacteria *in vitro* (Marcus et al., 1997). Some microbes, however, including several
624 plant- and animal-pathogenic fungi, as well as gram-negative bacteria appear to be insensitive
625 (Marcus et al., 1997). It has been concluded that, to confer broad spectrum antimicrobial
626 activity, MiAMP1 must act on molecules and/or cell structures common to a wide range of
627 microbial organisms (Marcus et al., 1997). Although a specific mode of action for MiAMP1
628 has not yet been determined (Stephens et al., 2005), more functional information is available
629 for Sp-AMP3, a homolog of this protein from Scots pine, *Pinus sylvestris* (Asiegbu et al.,
630 2003; Sooriyaarachchi et al., 2011). Purified Sp-AMP3 protein has antifungal activity against
631 the plant-pathogenic, root-rotting Basidiomycete *Heterobasidion annosum*, and as part of
632 this, causes morphological changes in the hyphae and spores of this fungus (Sooriyaarachchi
633 et al., 2011). To test the hypothesis that the biological function of Sp-AMP3 involves a fungal
634 cell wall target, carbohydrate-binding assays were performed. These assays revealed that Sp-
635 AMP3 binds to both soluble and insoluble β -1,3-glucans with high affinity, but not to
636 insoluble chitin or chitosan (Sooriyaarachchi et al., 2011). Based on these results, it was
637 hypothesized that differences in cell wall composition would allow Sp-AMP3 to act on some,
638 but not all fungi (Sooriyaarachchi et al., 2011). It is possible that in sensitive fungi, Sp-Amp3
639 binding interferes with glucan assembly. This could then alter cell wall structure, causing the

640 abovementioned morphological changes, or could result in cell lysis through compromised
641 cell wall integrity (Sooriyaarachchi et al., 2011).

642 The three remaining ipiSSPs, specifically CfCE24, CfCE56 and CfCE58, were
643 predicted to be structurally homologous to KP6, a killer toxin secreted by specific strains of
644 the fungal corn smut pathogen *U. maydis*. These strains exhibit a “killer” phenotype, which is
645 due to persistent infection by a KP6-producing double-stranded RNA *Totivirus*, P6. Upon
646 secretion, KP6 kills competing, uninfected strains of *U. maydis* (Allen et al., 2013b; Koltin
647 and Day, 1975). Resistance to KP6 in these killer strains is provided by *p6r*, an unknown,
648 non-virus-encoded recessive nuclear host gene (Finkler et al., 1992; Koltin and Day, 1976;
649 Puhalla, 1968). Although a preliminary study suggested that KP6 was only active against
650 grass smut fungi of the order Ustilaginales, with several bacterial and other fungal species
651 shown to be insensitive (Koltin and Day, 1975), it is now clear that KP6 has antifungal
652 activity against other selected plant-pathogenic fungi (Smith and Shah, 2015).

653 KP6 is translated as a single polypeptide, but is processed into two subunits, KP6 α
654 and KP6 β , by a kexin protease during passage through the ER–Golgi secretory pathway. This
655 processing involves the removal of a central 31-amino acid residue linker region (Tao et al.,
656 1990), which may serve to keep the two subunits in an inactive protoxin form until the final
657 stages of export (Allen et al., 2013a). Both subunits adopt a core α/β -sandwich fold (Allen et
658 al., 2013a; Li et al., 1999). KP6 functions only as a heterodimer, with both subunits required
659 for cytotoxic activity (Peery et al., 1987). Assays where sensitive *U. maydis* cells were treated
660 with KP6 α or KP6 β alone, or with one subunit after another, but with a washing step in
661 between, strongly suggest that KP6 α is responsible for targeting the cell, while KP6 β is
662 cytotoxic (Peery et al., 1987). The specific mode of action for KP6, however, remains
663 unclear. An early study found that spheroplasts derived from a sensitive strain of *U. maydis*
664 were insensitive to KP6, but when the cell wall was given time to regenerate, sensitivity
665 could be restored (Steinlauf et al., 1988). Based on this result, it was inferred that some sort
666 of recognition site was located on the cell wall that then directed KP6 to its cellular target
667 (Steinlauf et al., 1988). However, as was pointed out by Allen et al. (2013b), the cell wall-
668 degrading enzyme preparation used to generate the spheroplasts, Novozyme 234, has residual
669 protease activity (Hamlyn et al., 1981). For this reason, a proteinaceous cell membrane
670 receptor for KP6 cannot yet be ruled out. One possibility is that KP6 α forms strong
671 interactions with membrane-associated proteins of the target cell, with KP6 β subsequently
672 recruited to the plasma membrane or imported to an intracellular target to cause cell lysis
673 (Allen et al., 2013a). Interestingly, limited amino acid sequence homology was identified

674 between CfCE72 (NTR) and the KP6-like ipiSSPs CfCE24, CfCE56 and CfCE58. This
675 suggests that CfCE72 (NTR) also adopts a KP6-like fold. A putative kexin protease cleavage
676 site is located between the NTR and CTR (β/γ -crystallin-like domain) of CfCE72, implying
677 that this ipiSSP undergoes similar post-translational processing to KP6 upon passage through
678 the ER–Golgi secretory pathway.

679 In total, 10% of the *C. fulvum* ipiSSPs (seven of 70) are predicted to possess a domain
680 typical of antimicrobial proteins. This raises the possibility that *C. fulvum* dedicates a
681 significant proportion of its apoplastic secretome to functions associated with microbial
682 antagonism, perhaps to outcompete other microbial organisms for nutrients and space in the
683 apoplastic environment, or to provide a form of self-defence (Rovenich et al., 2014). Further
684 studies are now required to establish whether any overlap exists between the *in planta*
685 functions of the β/γ -crystallin/KP6 proteins and the ipiSSPs Ecp4, Ecp7, CfCE24, CfCE44,
686 CfCE56, CfCE58 and CfCE72.

687 Of course, it remains possible that the predicted similarities in tertiary structure do not
688 extend to biological function. Instead, these folds may be more common than previously
689 thought, irrespective of whether they have evolved from an ancestral protein or by convergent
690 evolution, providing solutions to typical problems faced at the hostile host–pathogen
691 interface. For example, the abovementioned folds may provide enhanced stability in protease-
692 rich environments. Alternatively, they may provide a flexible molecular scaffold for
693 functional diversification and/or the evasion of recognition by corresponding host immune
694 receptors. Recently, the IP effectors Avr1-CO39, AVR-Pia and AvrPiz-t from *M. oryzae*, as
695 well as the ToxB effector from *P. tritici-repentis*, were found to be structurally related (de
696 Guillen et al., 2015). Structure-informed pattern searches subsequently revealed that several
697 other effector candidates from Sordariomycete and Dothideomycete plant pathogens likely
698 share this fold. This led the authors to hypothesize that “the enormous number of sequence-
699 unrelated Ascomycete effectors may in fact belong to a restricted set of structurally
700 conserved effector families” (de Guillen et al., 2015). Certainly, the predicted structural
701 relationship between Alt a 1 and CfCE5/CfCE25/CfCE65 further supports this hypothesis.

702 Of the 70 apoplastic ipiSSPs from *C. fulvum*, 41 were screened for recognition by
703 wild tomato accessions using an effectoromics approach based on the PVX transient
704 expression system (Hammond-Kosack et al., 1995; Takken et al., 2000). Such an approach
705 has already proven to be successful for the identification of plants carrying immune receptor
706 genes active against other pathogens. For example, of 54 RXLR effectors from the oomycete
707 potato late blight pathogen *Phytophthora infestans*, 31 were found to trigger an HR in one or

708 more of 10 resistant wild *Solanum* accessions, with each accession recognizing between five
709 and 24 effectors (Vleeshouwers et al., 2008). Using the same set of 54 RXLR effectors, 48
710 were then shown to trigger an HR in one or more of 42 accessions of pepper (*Capsicum*
711 *annuum*), a non-host of *P. infestans*, with each accession recognizing between one and 36
712 effectors (Lee et al., 2014). In the current study, nine *C. fulvum* ipiSSPs (Ecps) were found to
713 trigger an HR in one or more of 14 specific wild accessions of tomato. This suggests that nine
714 new IP effectors of this fungus, as well as nine new corresponding *Cf* immune receptor genes,
715 have been uncovered. One of the recognized Ecps, Ecp11-1, is a homolog of AvrLm3, an IP
716 effector from *L. maculans* (Plissonneau et al., 2016). This suggests that both tomato and
717 Brassica carry an immune receptor capable of recognizing this class of effector.

718 Consistent with *Ecp1*, *Ecp2-1*, *Ecp4* and *Ecp5* (Stergiopoulos et al., 2007), but in
719 contrast to *Avr2*, *Avr4*, *Avr4E*, *Avr5* and *Avr9* (Iida et al., 2015; Mesarich et al., 2014;
720 Stergiopoulos et al., 2007), all new *Ecp* genes were found to exhibit limited allelic variation
721 across strains collected from around the world. As has been suggested for *Ecp1*, *Ecp2-1*,
722 *Ecp4* and *Ecp5* (Stergiopoulos et al., 2007), this limited allelic variation could reflect a lack
723 of selection pressure imposed on the pathogen to overcome *Cf-Ecp* immune receptor-
724 mediated resistance, since, as far as we are aware, none of the putative corresponding *Cf*
725 immune receptor genes have yet been deployed in commercial tomato cultivars.
726 Alternatively, this lack of allelic variation could reflect selective constraints on the Ecps to
727 maintain their protein sequences (i.e. to ensure full virulence of the pathogen). Of note, all
728 new *Ecp* genes, with the exception of *Ecp14-1*, are associated with repetitive elements in the
729 genome of *C. fulvum* strain 0WU. It is possible that homologous recombination between
730 flanking repeat elements could result in the deletion of these genes, like that hypothesized for
731 strains lacking the repeat-associated IP effector genes *Avr4E*, *Avr5* or *Avr9* (Mesarich et al.,
732 2014; van Kan et al., 1991; Westerink et al., 2004). Thus, to increase potential durability, new
733 *Cf* immune receptor genes should be stacked in resistant tomato cultivars.

734 In our study, we frequently observed that not all five representatives of a given
735 *S. corneliomuelleri*, *S. peruvianum*, or *S. pimpinellifolium* accession recognized an Ecp
736 effector. This is not surprising, because both *S. corneliomuelleri* and *S. peruvianum* are
737 typically self-incompatible, while *S. pimpinellifolium* is facultatively self-compatible (Peralta
738 and Spooner, 2006). In other words, genetic variation is expected to exist between
739 representatives of accessions from these species, with this variation extending to the presence
740 or absence of corresponding functional *Cf* immune receptor gene alleles. This may explain
741 why CfCE19 (Ecp17) gave such a strong HR in accession CGN 24034 using the toothpick

742 assay (Fig. S4), but no HR in the agroinfiltration assay (i.e. plants lacking a corresponding
743 functional immune receptor gene allele have been missed by chance) (Fig. S15). This may
744 also be true for Ecp9-1 on CGN 15392 (*S. arcanum* [typically self-incompatible]; Fig. S9),
745 Ecp10-1 on CGN 14356 (Fig. S10), Ecp11-1 on CGN 14357 (Fig. S11), and Ecp13 on CGN
746 14353 (Fig. S12).

747 *Cf* immune receptor genes present in self-compatible accessions can be easily
748 introgressed into commercial and breeder's cultivars of *S. lycopersicum* by backcrossing. In
749 cases of incompatibility, it may be possible to avoid the problems associated with barriers to
750 genetic crossing through a more extensive screen of wild tomato germplasm to identify self-
751 compatible species capable of recognizing the Ecps. This strategy has been successful for the
752 identification of wild potato species that recognize the AVRblb1 IP effector of *P. infestans*
753 (Vleeshouwers et al., 2008). Using an effectoromics approach based on the PVX transient
754 expression system, it was initially determined that the wild potato species *Solanum*
755 *bulbocastanum*, which is not directly sexually compatible with cultivated potato, *Solanum*
756 *tuberosum*, carries an immune receptor gene, *RB/Rpi-blb1*, corresponding to *AVRblb1*
757 (Vleeshouwers et al., 2008). As direct introgression of *RB/Rpi-blb1* from *S. bulbocastanum* to
758 *S. tuberosum* is not possible, additional screening was carried out to identify wild potato
759 accessions that are both sexually compatible with cultivated potato and that recognise
760 AVRblb1. HR-associated recognition of AVRblb1 was quickly detected in the sexually
761 compatible species *Solanum stoloniferum*, which was subsequently found to carry *Rpi-sto1*, a
762 functional homolog of *RB/Rpi-blb1* (Vleeshouwers et al., 2008). Importantly, in our study,
763 several accessions were found to recognize the same Ecp effectors, suggesting that this
764 approach could be possible in tomato. Further support is provided by the fact that the *Cf-9*
765 and *Cf-4* immune receptor genes are conserved across the *Solanum* genus (Kruijt et al., 2005;
766 Laugé et al., 2000; van der Hoorn et al., 2001b).

767 The finding that most new HR-eliciting Ecps have homologs in other plant-
768 pathogenic fungal species raises the possibility of cross-species resistance. In support of this
769 possibility, the *Cf-4* immune receptor has been shown to recognize homologs of Avr4 from
770 *D. septosporum*, *P. fijiensis* and *Pseudocercospora fuligena* (black leaf mould disease of
771 tomato) (de Wit et al., 2012; Kohler et al., 2016; Stergiopoulos et al., 2010), while the
772 *Cf-Ecp2-1* immune receptor has been shown to recognize homologs of Ecp2-1 from
773 *D. septosporum* and *P. fijiensis* (de Wit et al., 2012; Stergiopoulos et al., 2012). It must be
774 pointed out, however, that the *Cf-4* immune receptor does not recognize homologs of Avr4
775 from *Cercospora apii*, *Cercospora beticola* and *Cercospora nicotianae* (leaf spot disease of

776 celery, beet and tobacco, respectively) (Mesarich et al., 2016; Stergiopoulos et al., 2012).
777 With this in mind, it is clear that to provide effective resistance in a recipient plant species,
778 the product of any transferred *Cf* immune receptor gene must recognize an epitope (direct
779 recognition) or virulence function (indirect recognition) conserved to both the corresponding
780 *C. fulvum* effector and its homolog from the target fungal pathogen.

781

782 **CONCLUSIONS**

783 In this study, proteomics and transcriptome sequencing were used to identify a set of 70
784 apoplastic ipiSSPs from *C. fulvum*, which is made up of all 11 IP effectors of this fungus, as
785 well as 59 CfCEs. These ipiSSPs provide new insights into how *C. fulvum* promotes
786 colonization of the tomato leaf apoplast. Using an effectoromics approach, nine CfCEs (Ecps)
787 were found to be recognized by specific wild accessions of tomato. These accessions likely
788 carry new *Cf* immune receptor genes available for incorporation into cultivated tomato.

789

790 **MATERIALS AND METHODS**

791 **General.**

792 In this study, all kits and reagents were used, unless otherwise specified, in accordance with
793 the manufacturer's instructions.

794

795 ***C. fulvum* strains and tomato accessions.**

796 *C. fulvum* strains and tomato accessions used in this study are shown in Tables S5 and S3,
797 respectively.

798

799 **Isolation of IWF from the leaf apoplast of *C. fulvum*-infected tomato.**

800 Four- to five-week-old H-Cf-0 tomato plants were inoculated with strain 0WU, 4, IPO 1979,
801 or IPO 2559 of *C. fulvum* (compatible interactions). For this purpose, conidia preparation,
802 inoculation, and growth conditions were identical to that described by Mesarich et al. (2014).
803 At 10–17 dpi, IWF was harvested from tomato leaves visibly infected with *C. fulvum* using a
804 previously described protocol (de Wit and Spikman, 1982; Joosten, 2012). Leaf debris and
805 fungal material were then removed by centrifugation at $12,000 \times g$ and 4°C for 20 min, and
806 the IWF samples stored at -20°C until required.

807

808

809

810 **Preparation of IWF samples for LC–MS/MS analysis.**

811 Frozen IWF samples were thawed on ice and any precipitant formed during the freeze-thaw
812 process removed by centrifugation at $12,000 \times g$ and 4°C for 20 min. IWF samples were
813 concentrated 3–300 \times by: (i) pressure filtration at 4°C using an Amicon 8400 series Stirred
814 Cell Ultrafiltration Unit (EMD Millipore) fitted with an Ultracel regenerated cellulose PLAC
815 1 kDa nominal molecular weight limit (NMWL) ultrafiltration membrane disc (EMD
816 Millipore); (ii) centrifugation at $4,000 \times g$ and 4°C in a 3 kDa NMWL Amicon Ultra-15
817 Centrifugal Filter Unit (EMD Millipore) or a Vivaspin 20 3 kDa molecular weight cut-off
818 (MWCO) Polyethersulfone (PES) ultrafiltration device (GE Healthcare); or (iii) sequential
819 acetone precipitation, as described by May et al. (1996), with final resuspension in 1 ml
820 dH_2O . Following concentration, IWF samples were transferred to 2 ml LoBind
821 microcentrifuge tubes (Eppendorf), and stored at -20°C until required for further processing.
822 When required, frozen IWF samples were thawed on ice and any precipitant formed during
823 the freeze-thaw process removed by centrifugation at $12,000 \times g$ and 4°C for 20 min. A filter-
824 aided sample preparation protocol (Lu et al., 2011), or an in-gel digestion protocol (Karimi
825 Jashni et al., 2015), both based on trypsin digestion, were then used to prepare samples for
826 LC–MS/MS analysis.

827

828 **LC–MS/MS analysis.**

829 IWF samples were analysed by nano-scale (n)LC–MS/MS with a Proxeon EASY nLC system
830 connected to a LTQ-Orbitrap XL mass spectrometer (Lu et al., 2011) at the Laboratory of
831 Biochemistry, Wageningen University. LC–MS runs and associated MS/MS spectra were
832 analysed with the MaxQuant v1.3.0.5 suite (Cox and Mann, 2008), with default settings
833 applied to the integrated Andromeda peptide search engine (Cox et al., 2011), bar one
834 exception: extra variable modifications were set for the de-amidation of Asn and Gln.
835 MS/MS spectra were searched against one of four sequence databases. These were built from:
836 (i) a collection of common contaminants including, for example, BSA (P02769; bovine serum
837 albumin precursor), trypsin (P00760; bovine), trypsin (P00761; porcine), keratin K22E
838 (P35908; human), keratin K1C9 (P35527; human), keratin K2C1 (P04264; human) and
839 keratin K1CI (P35527; human); (ii) a six-frame translation of tomato (*S. lycopersicum* cv. H-
840 Cf-0) genome sequence (Tomato Genome Consortium, 2012); (iii) the predicted protein
841 catalogue of *C. fulvum* strain 0WU (de Wit et al., 2012; Mesarich et al., 2014), as well as a
842 six-frame translation of the most highly abundant *de novo*-assembled *in vitro* and *in planta*
843 RNA-Seq reads of this fungus (Mesarich et al., 2014); and (iv) a six-frame translation of the

844 repeat-masked *C. fulvum* strain 0WU genome sequence (de Wit et al., 2012). The “label-free
845 quantification (LFQ)” and “match between runs” (set to 2 min) options were enabled. De-
846 amidated peptides were allowed to be used for protein quantification. All other quantification
847 settings were kept at default. Filtering and further bioinformatic analysis of the
848 MaxQuant/Andromeda workflow output and the analysis of abundances for the identified
849 proteins were performed with the Perseus v1.3.0.4 module as part of the MaxQuant suite.
850 Peptides and proteins with a false discovery rate of less than 1%, as well as proteins with at
851 least one peptide across two or more IWF samples, or two or more independent peptides in a
852 single IWF sample, were considered as reliable identification. Reversed hits were deleted
853 from the MaxQuant results table, as were tomato and contamination hits.

854

855 **Identification of apoplastic ipiSSPs from *C. fulvum*.**

856 *C. fulvum* SSPs directed to the apoplastic environment via the classical/conventional
857 secretory pathway (i.e. SSPs that possess an N-terminal signal peptide, but lack a GPI anchor
858 modification site, a transmembrane domain, or a putative C-terminal ER retention/retention-
859 like signal) were targeted for identification in the protein set identified by LC–MS/MS
860 analysis. The SignalP v3.0 (Bendtsen et al., 2004) and v4.1 (Petersen et al., 2011) servers
861 were used for signal peptide prediction, while the big-PI Fungal Predictor (Eisenhaber et al.,
862 2004) and TMHMM v2.0 (Krogh et al., 2001) servers were used for the prediction of GPI
863 anchor modification sites and transmembrane domains, respectively.

864 Pre-existing RNA-Seq transcriptome sequencing data (Mesarich et al., 2014) from a
865 compatible *in planta* time course involving *C. fulvum* strain 0WU and *S. lycopersicum* cv.
866 H-Cf-0 (4, 8 and 12 dpi), as well as from strain 0WU grown *in vitro* in PDB or Gamborg B5
867 liquid media (4 dpi), were used to predict which of the SSPs identified by LC–MS/MS
868 analysis are encoded by *in planta*-induced genes. Although these data lack biological
869 replicates, they have been extensively validated through RT-qrtPCR experiments (Mesarich
870 et al., 2014; this study). Paired-end RNA-Seq reads were re-mapped to the strain 0WU
871 genome sequence (de Wit et al., 2012) with Bowtie v2-2.1.0 (Langmead and Salzberg, 2012)
872 and TopHat v2.0.12 (Kim et al., 2013) using a custom script (Methods S1). Transcript
873 assembly and abundance estimations were then performed using Cufflinks v2.0.2 (Trapnell et
874 al., 2010), with transcript abundance expressed as FPKM values. SSPs were deemed to be *in*
875 *planta*-induced if they were encoded by genes that had a maximum *in planta* FPKM value of
876 ≥ 50 at 4, 8 or 12 dpi that exceeded their maximum *in vitro* FPKM value at 4 dpi by a factor
877 of ≥ 1.5 . Gene exon–intron boundaries were confirmed using the same RNA-Seq data.

878 **General homology screening and alignments.**

879 Reciprocal BLASTp screens (Altschul et al., 1997) were used to identify homologs of the
880 apoplastic ipiSSPs from *C. fulvum* present in publicly available databases at NCBI and JGI
881 (Grigoriev et al., 2011). In all cases, hits with an expect (E)-value of $>1E-02$ were not
882 considered. Likewise, proteins that did not have the same number of Cys residues as the
883 query sequence were not considered. For those proteins for which a homolog could not be
884 identified in JGI, a tBLASTn screen was carried out against the genome collection with the
885 same E-value cut-off. Homologous proteins were aligned using the Clustal Omega server
886 (Sievers et al., 2011).

887

888 **Motif identification.**

889 The MEME v4.11.2 server (Bailey et al., 2006) was used to identify short sequence motifs
890 shared between members of the *C. fulvum* apoplastic ipiSSP set. For this purpose, the
891 expected distribution of motif sites was set to any number of repetitions per sequence, the
892 number of motifs to find was set to 100, the minimum and maximum length of motif was set
893 to four and 10 amino acid residues, respectively, the minimum and maximum number of sites
894 per motif was set to five and 100, respectively, and the location of motif sites was set to given
895 strand only. All other settings were kept as default.

896

897 **Structural modelling.**

898 Three-dimensional protein structure prediction servers were used to infer possible structural
899 relationships between apoplastic ipiSSPs of *C. fulvum* and proteins with characterized tertiary
900 structures in the RCSB PDB (Berman et al., 2000). Only those ipiSSPs with no homology to
901 proteins present in NCBI or JGI, or those with homology to hypothetical proteins of unknown
902 function in these databases, were investigated. The prediction servers employed were
903 HHPred (Hildebrand et al., 2009; Söding et al., 2005), SPARKS-X (Yang et al., 2011),
904 MUSTER (Wu and Zhang, 2008), FFAS03/FFAS-3D (Jaroszewski et al., 2005; Xu et al.,
905 2013), FUGUE v2.0 (Shi et al., 2001), RaptorX (Källberg et al., 2012), pGenTHREADER
906 (Lobley et al., 2009), Phyre2 (Kelley et al., 2015) and I-TASSER (Zhang, 2008). Structural
907 modelling was done with MODELLER (HHPred) (Webb and Sali, 2002) and RaptorX, and
908 was visualized using PyMOL (DeLano, 2002). For each server, default settings were used.

909

910

911

912 **Repeat identification.**

913 BLASTn was used to identify repetitive nucleotide sequences shared between the genome
914 scaffolds harbouring an *Ecp* gene and the rest of the *C. fulvum* strain 0WU genome. Only
915 those sequence repeats of ≥ 100 nucleotides in length, and sharing $\geq 80\%$ identity, with an
916 E-value threshold of $1E-05$, were considered. The maximum total number of sequence
917 alignments considered per scaffold was set to 5,000.

918

919 **Homology screening and expression profiling in *Dothistroma septosporum*.**

920 Reciprocal BLASTp and tBLASTn screens were used to identify homologs of the apoplastic
921 ipiSSPs from *C. fulvum* in the *D. septosporum* strain NZE10 protein catalogue and genome
922 (de Wit et al., 2012) at JGI, respectively, with hits possessing an E-value of $>1E-02$ not
923 considered. RNA-Seq data from *D. septosporum* strain NZE10 (Bradshaw et al., 2016) were
924 used to determine which of the homologs are most relevant to the *D. septosporum*–*Pinus*
925 *radiata* interaction. More specifically, transcript abundance data from one *in vitro* growth
926 condition (fungal mycelia [FM] in *Dothistroma* liquid medium) and three *in planta* growth
927 conditions (epiphytic/biotrophic [early], initial necrosis [mid] and mature sporulating lesion
928 [late]), expressed as reads per million per kb (RPMK) values, were used. Genes deemed
929 relevant to the interaction had to have a maximum *in planta* RNA-Seq RPMK value of ≥ 50 at
930 the early, mid, or late time point. Furthermore, this value had to exceed the gene's *in vitro*
931 RPMK value by a factor of at least 1.5.

932

933 **PVX-mediated transient expression assays.**

934 Tomato accessions (Table S3) were screened for their ability to recognize apoplastic ipiSSPs
935 through the elicitation of an HR using the PVX-based transient expression system
936 (Hammond-Kosack et al., 1995; Takken et al., 2000). For this purpose, the cDNA sequence
937 encoding a mature ipiSSP was fused downstream of the cDNA sequence encoding the *N.*
938 *tabacum* PR1A signal peptide (i.e. for secretion into the apoplastic environment), and cloned
939 into the binary PVX vector pSfinx behind the *Cauliflower mosaic virus* (CaMV) 35S
940 promoter (Takken et al., 2000). These steps were carried out using the protocol of Mesarich
941 et al. (2014) (overlap extension PCR and restriction enzyme-mediated cloning) or Mesarich
942 et al. (2016) (overlap extension PCR and GATEWAY cloning [Invitrogen]) with the primer
943 pairs listed in Table S6. Constructs were transformed into *Agrobacterium tumefaciens* strain
944 GV3101 for agroinfection of tomato by electroporation using the method of Takken et al.
945 (2000). For localized transient expression assays in tomato, transformants were prepared

946 using the protocol described by Stergiopoulos et al. (2010), but with re-suspension in a final
947 volume of 0.5 ml MMA-acetosyringone, and inoculated into fully expanded leaves by
948 localized wounding on each side of the main vein with a toothpick (Luderer et al., 2002a;
949 Takken et al., 2000). For systemic transient expression assays, transformants were again
950 prepared using the method of Stergiopoulos et al. (2010), with final resuspension in MMA-
951 acetosyringone to an OD₆₀₀ of 1.0, and infiltrated into both cotyledons of a seedling at 10 d
952 post-germination with a 1-ml needleless syringe (Mesarich et al., 2014). The presence or
953 absence of an HR was visually assessed at 10 d post-wounding and 3 weeks post-infiltration
954 for systemic and localized transient expression assays, respectively.

955

956 **Tomato infection assays.**

957 Tomato accessions (Table S3) were inoculated with *C. fulvum* strain 2.4.5.9.11 IPO using the
958 method described by Mesarich et al. (2014), with resistance or susceptibility to this strain
959 visually assessed across three independent plants at 14 dpi.

960

961 **RT-qrtPCR gene expression analysis.**

962 Leaf samples from compatible *C. fulvum* strain 0WU–*S. lycopersicum* cv. H-Cf-0 interactions
963 at 4, 8, 12 and 16 dpi, as well as fungal samples from *C. fulvum* strain 0WU PDB and
964 Gamborg B5 liquid media cultures at 4 dpi, were collected by Mesarich et al. (2014) and
965 stored at –80°C. Total RNA extraction from each sample, as well as subsequent cDNA
966 synthesis, was carried out according to the protocol of Griffiths et al. (2017). RT-qrtPCR
967 experiments were performed on cDNA samples using the method described by Ökmen et al.
968 (2013) and the primers listed in Table S6. The *C. fulvum actin* gene was targeted as a
969 reference for normalization of gene expression, and results were analysed according to the 2⁻
970 ΔCt method (Livak and Schmittgen, 2001). Results were the average of three biological
971 replicates.

972

973 **Allelic variation analysis.**

974 *C. fulvum* strains (Table S5) were grown in PDB, with conidia preparation, PDB inoculation,
975 and culture conditions identical to that described by Mesarich et al. (2014). Genomic DNA
976 was extracted from each strain according to the method of van Kan et al. (1991). Genes
977 targeted for an analysis of allelic variation were amplified from genomic DNA by PCR using
978 the protocol and reagents described by Mesarich et al. (2014), and the primers listed in Table
979 S6. PCR amplicons were purified using an illustra GFX PCR DNA and Gel Band Purification

980 Kit (GE Healthcare), and were directly sequenced at MacroGen Inc. (Korea) using the same
981 gene-specific primers employed for PCR amplification.

982

983 **ACKNOWLEDGEMENTS**

984 We thank Simon Williams (Australian National University, Canberra, Australia) for advice
985 on protein structure prediction, Andre Sim (Massey University, Palmerston North) for
986 mapping RNA-Seq reads to the *D. septosporum* genome, Sjef Boeren (Wageningen
987 University, the Netherlands) for performing LC-MS/MS experiments, and Willem van
988 Dooijeweert (Centre for Genetic Resources, the Netherlands) for providing tomato seed.
989 Financial assistance for this research was provided by Wageningen University, the Royal
990 Netherlands Academy of Arts and Sciences, European Research Area-Plant Genomics, the
991 Centre for BioSystems Genomics (part of the Netherlands Genomics Initiative/Netherlands
992 Organization for Scientific Research; project TD8-35), and the New Zealand Bio-Protection
993 Research Centre. Financial assistance for CW was provided by the Chinese Scholarship
994 Council. The authors declare no conflicts of interest.

995

996 **AUTHOR CONTRIBUTIONS**

997 CHM, BÖ, REB, MDT and PJGMdW conceived the project. CHM, CHD and
998 AvdB performed the bioinformatic analyses. CHM, BÖ, HR, SAG, CW, MKJ, AM, JC, LH
999 and HGB carried out the experimental work. CHM wrote the manuscript. All authors read
1000 and approved the final manuscript.

1546 **TABLE**

1547 **Table 1.** Apoplastic *in planta*-induced small secreted proteins (ipiSSPs) of *Cladosporium*
 1548 *fulvum* produced during colonization of susceptible tomato (*Solanum lycopersicum* cv.
 1549 Heinz-Cf-0).

ipiSSP name¹	GenBank accession number	Protein length (aa)²	No. cysteine residues³	Brief description and functional domains⁴
Avr2	CAD16675	78	8	IP effector recognized by the Cf-2 immune receptor. Cysteine protease inhibitor. Similar to hypothetical proteins
Avr4	CAA55403	135	8	IP effector recognized by the Cf-4 immune receptor. Protector of cell wall chitin. CBM_14 domain (PF01607)
Avr4E	AAT28196	121	6	IP effector recognized by the Cf-4E immune receptor. Novel
Avr5	AHY02126	103	10	IP effector recognized by the Cf-5 immune receptor. Novel
Avr9	P22287	63	6	IP effector recognized by the Cf-9 immune receptor. Cysteine knot fold. Similar to hypothetical proteins. Homolog of CfCE67
Ecp1	CAA78400	96	8	IP effector recognized by the Cf-Ecp1 immune receptor. Similar to hypothetical proteins
Ecp2-1	CAA78401	165	4	IP effector recognized by the Cf-Ecp2 immune receptor. Hce2 domain (PF14856)
Ecp4	CAC01609	119	6	IP effector recognized by the Cf-Ecp4 immune receptor. Predicted β/γ -crystallin-like fold. Similar to hypothetical proteins. Paralog of Ecp7. Homolog of CfCE72
Ecp5	CAC01610	115	6	IP effector recognized by the Cf-Ecp5 immune receptor. Similar to hypothetical

proteins				
Ecp6	AQA29283	222	8	IP effector recognized by the Cf-Ecp6 immune receptor. Suppresses chitin-triggered immunity. Three LysM domains (PF01476)
Ecp7	AQA29284	116	6	Predicted β/γ -crystallin-like fold. Similar to hypothetical proteins. Paralog of Ecp4. Homolog of CfCE72
Ecp8/ CfCE6	AQA29209	105	8	Possible IP effector. Novel
Ecp9-1/ CfCE9	AQA29212	88	6	Possible IP effector. Similar to hypothetical proteins. Paralog of Ecp9-9/CfCE49
Ecp9-9/ CfCE49	AQA29252	90	6	Similar to hypothetical proteins. Paralog of Ecp9-1/CfCE9
Ecp10-1/ CfCE14	AQA29217	70	6	Possible IP effector. Similar to hypothetical proteins. Paralog of Ecp10-2/CfCE31
Ecp10-2/ CfCE31	AQA29234	67	6	Similar to hypothetical proteins. Paralog of Ecp10-1/CfCE14
Ecp11-1/ CfCE18	AQA29221	165	10	Possible IP effector. Homolog of the AvrLm3 and AvrLmJ1 IP effectors from <i>Leptosphaeria maculans</i>
Ecp12/ CfCE26	AQA29229	133	8	Possible IP effector. Similar to hypothetical proteins
Ecp13/ CfCE33	AQA29236	73	10	Possible IP effector. Similar to hypothetical proteins
Ecp14-1/ CfCE55	AQA29258	206	12	Possible IP effector. Class II hydrophobin
Ecp15/ CfCE59	AQA29262	131	8	Possible IP effector. Similar to hypothetical proteins
Ecp16/ CfCE48	AQA29251	101	8	Possible IP effector. Novel

Ecp17/ CfCE19	AQA29222	62	6	Possible IP effector. Novel
CfPhiA-1/ CfCE11	AQA29214	195	4	Phialide protein. Paralog of CfPhiA-2/CfCE53
CfPhiA-2/ CfCE53	AQA29256	218	6	Phialide protein. Paralog of CfPhiA-1/CfCE11
CfCE3	AQA29206	81	10	Novel
CfCE4	AQA29207	162	8	Similar to hypothetical proteins. Paralog of CfCE16
CfCE5	AQA29208	166	4	Predicted Alt a 1 allergen-like fold. Similar to hypothetical proteins. Paralog of CfCE25 and CfCE65
CfCE7	AQA29210	184	8	Similar to hypothetical proteins
CfCE8	AQA29211	161	8	Similar to hypothetical proteins
CfCE12	AQA29215	91	4	Novel
CfCE13	AQA29216	92	4	Homolog of CfCE63. Novel
CfCE15	AQA29218	79	8	Similar to hypothetical proteins
CfCE16	AQA29219	130	8	Similar to hypothetical proteins. Paralog of CfCE4
CfCE20	AQA29223	65	6	Similar to hypothetical protein
CfCE22	AQA29225	67	4	Similar to hypothetical proteins
CfCE24	AQA29227	101	6	Predicted KP6-like fold. Similar to hypothetical proteins. Homolog of CfCE56, CfCE58 and CfCE72
CfCE25	AQA29228	149	4	Predicted Alt a 1 allergen-like fold. Similar to hypothetical proteins. Paralog of CfCE5 and CfCE65
CfCE27	AQA29230	93	10	Novel
CfCE30	AQA29233	197	4	IgE-binding protein. Paralog of CfCE70
CfCE34	AQA29237	210	8	Similar to hypothetical proteins
CfCE35	AQA29238	92	8	Novel
CfCE36	AQA29239	70	8	Novel
CfCE37	AQA29240	73	10	Similar to hypothetical proteins

1575
1576 **Fig. 1.** Schematic representation of 10 apoplastic *Cladosporium fulvum* strain 0WU candidate
1577 effector (CfCE) proteins that trigger a hypersensitive response (HR) in one or more specific
1578 accessions of tomato. All 10 CfCE proteins are small, cysteine-rich, and are predicted to
1579 possess an amino (N)-terminal signal peptide for extracellular targeting to the tomato leaf
1580 apoplast. The predicted signal peptide of each CfCE protein is shown by black diagonal lines.
1581 Cysteine residues are shown by thick vertical bars. Numbers indicate the first and last amino
1582 acid residue of each protein. The predicted propeptide domain of CfCE33, ending with a
1583 predicted kexin protease cleavage site, is shown by black dashed diagonal lines. A
1584 glycine/leucine-rich region present in CfCE55 is shaded grey. Cysteine residues of CfCE55
1585 that are conserved with fungal hydrophobin proteins are shown by asterisks.

1586

1589

1590 **Fig. 2.** Nine *Cladosporium fulvum* candidate effectors (CfCEs) of strain 0WU trigger a
1591 systemic hypersensitive response (HR) in one or more specific accessions of tomato. Selected
1592 examples are shown. CfCEs were systemically produced in five representatives of each
1593 tomato accession (left) using the *Potato virus X* (PVX) transient expression system.
1594 Recombinant PVX was delivered by *Agrobacterium tumefaciens* (agroinfection) through
1595 cotyledon infiltration at 10 d post-seed germination. Two representatives of each tomato

1596 accession were inoculated with PVX alone (pSfinx empty vector; EV) (right). Plants
1597 exhibiting a systemic chlorotic or necrotic HR are shown by white asterisks. Plants without
1598 obvious mosaic symptoms (i.e. not infected with PVX) are shown by red asterisks.
1599 Photographs were taken at 21 d post-infiltration.

1684 **Fig. 5.** Genes encoding a hypersensitive response (HR)-eliciting extracellular protein (Ecp)

1685 exhibit limited allelic variation between strains of *Cladosporium fulvum*. Allelic variation

1686 was assessed across 10 distinct strains of *C. fulvum*, and was compared to strain 0WU. Open

1687 reading frames (encoding each mature protein) and introns are shown as white and black

1688 boxes, respectively. Regions of each *Ecp* gene predicted to encode an amino (N)-terminal

1689 signal peptide sequence are shown by black diagonal lines. DNA modifications leading to

1690 non-synonymous amino acid substitutions are shown by white flags. DNA modifications

1691 leading to synonymous amino acid mutations or changes to intronic sequences are shown by

1692 Ts. Numbers above each schematic represent the first and last nucleotide of each gene (i.e. of

1693 the ATG to STOP codons, respectively). Numbers on the bottom of each schematic represent

1694 the location of each DNA modification.
