23   **Abstract**

24   The spatial architecture of the islets of Langerhans is hypothesized to facilitate synchronized

25   insulin secretion between β cells, yet testing this *in vivo* in the intact pancreas is challenging.

26   *Robo βKO* mice, in which the genes *Robo1* and *Robo2* are deleted selectively in β cells, provide

27   a unique model of altered islet architecture without loss of β cell differentiation or islet damage

28   from diabetes. Combining *Robo βKO* mice with intravital microscopy, we show here that *Robo*

29   *βKO* islets lose synchronized intra-islet Ca^{2+} oscillations between β cells *in vivo*. We provide

30   evidence that this loss is not due to a β cell-intrinsic function of Robo, loss of Connexin36 gap

31   junctions, or changes in islet vascularization, suggesting that the islet architecture itself is

32   required for synchronized Ca^{2+} oscillations. These results will have implications for

33   understanding structure-function relationships in the islets during progression to diabetes as

34   well as engineering islets from stem cells.

2

Introduction

The islets of Langerhans, which comprise the endocrine pancreas, are highly organized micro-organs responsible for maintaining blood glucose homeostasis. Islets are composed of five endocrine cell types (α, β, δ, PP, and ε) which, in rodents, are arranged such that the β cells reside in the core of the islet, while other non-β endocrine cells populate the islet mantle[1]. Human islet architecture is more complex; however, it still follows non-random patterning in which multiple core-mantle-like units comprise a single islet[2]. In both rodent and human islets, respective stereotypical islet architectures prioritize homotypic over heterotypic interactions between endocrine cell types[3]. The biological reason for preferential homotypic interactions between endocrine cells is not completely clear, but it has been suggested to be important for dictating the level of Connexin36 (Cx36)-mediated electrical β cell-β cell coupling, thus controlling synchronization of glucose-stimulated insulin secretion (GSIS) between neighboring β cells[4,5].

Synchronous insulin secretion between β cells is triggered when glucose from the blood enters the β cells through glucose transporters. As this glucose is metabolized, the ratio of intracellular ATP/ADP in the cells increases. The rise in ATP causes ATP sensitive K^+ channels to close, resulting in membrane depolarization. The resultant depolarization causes voltage-gated Ca^{2+} channels to open, triggering an influx of Ca^{2+} into the cell, which in turn promotes exocytosis of insulin granules[6-8]. This chain of events is cyclical and thus results in oscillations of membrane potential, cytosolic Ca^{2+} levels, and insulin secretion in response to glucose[9]. Because β cells within an islet are gap-junctionally coupled, and thus electrically coupled, these oscillations are synchronous across all islet β cells[10]. It is thus hypothesized that preferential β

3

57   cell homotypic contact allows for the necessary amount of gap junctions to form between

58   neighboring β cells in order to synchronize the oscillations in an entire islet, facilitating pulsatile

59   insulin secretion[5,11]. Indeed, modeling experiments in which the number of homotypic β cell-β

60   cell nearest neighbor connections is lowered within an islet result in predicted perturbation of

61   synchronous Ca^{2+} oscillations[5]. If this *in silico* prediction is correct, then disrupting spatial

62   organization of the different endocrine cell types within the islet alone, without affecting any

63   other property of the cells, should be sufficient to disturb synchronized insulin secretion

64   between β cells. However, direct empirical evidence for this hypothesis is lacking.

65   Most genetic mouse models that show disruption of islet architecture also display

66   defects in glucose homeostasis[12]. However, in many of these models, the disrupted islet

67   architecture phenotype is linked to either developmental defects in β cell differentiation or

68   maturation[13-24] or to pathologies related to β cell damage in diabetes[25-30]. This introduces a

69   strong confounding factor for studying the role of islet architecture on β cell function.

70   Therefore current mouse models of disrupted islet architecture unsuitable for directly testing

71   the hypothesis that the preferential homotypic β cell-β cell interactions, dictated by canonical

72   islet architecture, regulate synchronized insulin secretion between β cells within the same islet.

73   Recently, we have described a mouse model in which the cell-surface receptors *Robo1*

74   and *Robo2* are deleted specifically in β cells (*Robo βKO*), resulting in disruption of canonical

75   endocrine cell type sorting within the islets[31]. Unlike other models of disrupted islet

76   architecture, the β cells in the islets of *Robo βKO* express normal levels of markers for β cell

77   differentiation and functional maturity, and do not display markers of β cell damage or stress.

78   We reasoned that this model would allow us to directly test the role of islet architecture on

79   synchronous islet oscillations between β cells in a fully differentiated, non-diabetic islet setting.

80

81   **Results**

82   *Robo βKO* **islets express mature β cell markers despite having disrupted islet architecture and**

83   **endocrine cell type intermixing**

84   We have previously shown that genetic deletion of *Robo1* and *Robo2* selectively in β

85   cells using either *Ins1-Cre; Robo1$^{\Delta/\Delta}$2$^{flx/flx}$* or *Ucn3-Cre; Robo1$^{\Delta/\Delta}$2$^{flx/flx}$* mice (*Robo βKO*) results in

86   disrupted islet architecture and endocrine cell type sorting without affecting β cell death,

87   proliferation, or the expression of the β cell maturation markers MafA and Ucn3[31]. To verify

88   that β cells in *Robo βKO* islet are truly mature, we expanded the analysis to look at transcript

89   levels of all maturity markers. We performed RNA sequencing and differential gene expression

90   analysis on FACS-purified β cells from both *Robo βKO* and control islets, and observed no

91   change in transcript levels of any hallmark β cell maturity or differentiation genes (*n*=2 mice of

92   each genotype; **Supplemental Figure 1**). Thus, unlike other mouse models with disrupted islet

93   architecture, β cells in *Robo βKO* islets maintain maturity and differentiation despite loss of

94   normal islet architecture.

95

96   *Robo βKO* **islets have fewer homotypic β cell-β cell contacts than control islets**

97   *In silico* simulations where the degree of β cell-β cell coupling is changed through a

98   decrease in homotypic nearest neighbors predict that disruption in islet architecture will disrupt

99   synchronous intra-islet Ca^{2+} oscillations and hormone secretion pulses[3,5,32]. To test whether β

100   cells in *Robo βKO* islets have fewer homotypic β cell neighbors on average than control islets,

101   we performed nearest neighbor analysis on islets from pancreatic sections from *Robo βKO* and

102   control mice (**Figure 1**). We found that *Robo βKO* islets possess significantly fewer β cell-β cell

103   contacts (*n*=9-11 islets for 3 mice from each genotype; control 75.35%, *Robo βKO* 50.37%,

104   *p*=0.01), and homotypic contacts in general when compared to control islets (*n*=9-11 islets for 3

105   mice from each genotype; control 83.7%, *Robo βKO* 64.43%, *p*=0.0008). We also found that

106   *Robo βKO* islets possess significantly more β cell-α cell contacts (*n*=9-11 islets for 3 mice from

107   each genotype; control 11.21%, *Robo βKO* 25.99%, *p*=0.02), and heterotypic contacts in general

108   when compared to control islets (*n*=9-11 islets for 3 mice from each genotype; control 16.3%,

109   *Robo βKO* 35.57%, *p*=0.0008). Together, this suggests that *Robo βKO* islets make fewer

110   homotypic β cell-β cell connections compared to control islets. We reasoned that the altered

111   degree of homotypic β cell-β cell interaction in *Robo βKO* islets together with the seemingly

112   retained β cell maturity provide a unique model by which to test the hypothesis that endocrine

113   cell type organization affects synchronous insulin secretion in the islet.

114

115   **Robo βKO islets display unsynchronized Ca^{2+} oscillations *in vivo***

116   To investigate how the reduced homotypic β cell-β cell connections in *Robo βKO* islets

117   affects insulin-secretion dynamics, we adopted a novel intravital Ca^{2+} imaging method which

118   enables imaging of islet Ca^{2+} dynamics *in situ* within the intact pancreas[33]. In brief, this method

119   employs an intravital microscopy (IVM) platform and adeno-associated viral (AAV) delivery of

120   insulin promoter-driven GCaMP6s, a fluorescent Ca^{2+} biosensor, to quantitate β cell Ca^{2+}

121   dynamics *in vivo* in both *Robo βKO* and control islets. This method thus allows for retention of

6

122   the islet's *in vivo* microenvironment, blood flow, and innervation, and provides more realistic

123   conditions than *in vitro* approaches allow for.

124   We verified that synchronous Ca^{2+} oscillations are maintained *in vivo* in islets by

125   measuring GCaMP6s intensity of β cells within AAV8-RIP-GCaMP6 infected islets of control

126   (*Robo WT*) mice (**Figure 2**). As expected, control mice displayed whole islet synchronous Ca^{2+}

127   oscillations for at least 10 minutes after glucose elevation (*n*=3 islets from 1 mouse; **Figure 2**

128   and **Supplemental Video 1**). We quantified the degree to which these oscillations are

129   synchronous within the islet by analyzing the amount of correlation between GCaMP6s active

130   areas within individual islets. While oscillations vary in frequency between islets, the degree of

131   correlation between β cells within any one islet is very high, confirming that control islets

132   possess highly synchronous intra-islet Ca^{2+} oscillation *in vivo* (fraction of GCAMP6s activity with

133   correlated Ca^{2+} oscillations=0.97±0.005, n=3 islets from 1 mouse; see Figure 4A).

134   Conversely, we found that most *Robo βKO* islets display asynchronous intra-islet Ca^{2+}

135   oscillations *in vivo* (**Figure 3, Supplemental Figure 2, Supplemental Videos 2 and 3**).

136   Quantification of this asynchronous behavior through correlation analysis of GCaMP6s activity

137   within individual *Robo βKO* islets revealed significant reduction in intra-islet correlated

138   oscillation areas compared to controls (fraction of GCAMP6s activity with correlated Ca^{2+}

139   oscillations=0.62±0.1, *n*=8 islets from 4 mice, *p*<0.01; **Figure 4A**). Further, asynchronous *Robo*

140   *βKO* islets showed spatially distinct areas within the islet that oscillated synchronously with

141   immediate β cell neighbors but not with more distant regions within the same islet (**Figure 3C-**

142   **D, and Supplemental Figure 2**). This was not due to differences in the proportion of GCaMP6s

143   positive cells showing elevated Ca^{2+} activity within *Robo βKO* islets compared to controls

7

144   (control islets 0.98±0.008 fraction active, *n*=3 islets from 1 mouse; *Robo βKO* islets 0.96±0.02

145   fraction active, *n*=5 islets from 3 mice, *p*=0.35; **Figure 4B**).

146   Interestingly, 3 out of the 8 *Robo βKO* islets imaged showed synchronous Ca^{2+} activity in

147   greater than 90% of GCaMP6s positive areas (**Figure 4A, Supplemental Figure 3 and**

148   **Supplemental video 4**). Moreover, upon performing organ clearing and imaging on *Robo βKO*

149   pancreata, we observed multiple islets with relatively few α cells penetrating the β cell core

150   (**Figure 5, Supplemental Videos 5 and 6**)*. It is likely that those *Robo βKO* islets with normal

151   architecture are the same islets which retain synchronous Ca^{2+} oscillations. Together, these

152   observations suggest that some mechanisms governing synchronous Ca^{2+} oscillations within an

153   islet are not controlled intrinsically by Robo expression within β cells. This fits with the

154   hypothesis that architecture of the islet itself facilitates synchronous oscillations.

155   Further, analysis of the speed of wave propagation and time lag in the highly correlated

156   *Robo βKO* islets showed a trend towards a reduction in wave propagation speed (**Figure 4C**) and

157   an increase in time lag (**Figure 4D**) when compared to controls, though these failed to reach the

158   threshold for statistical significance (control islets wave propagation: 119.5±49.13µm/sec, *n*=3

159   islets from 1 mouse; *Robo βKO* islets wave propagation: 38.67±16.6µm/sec, *n*=3, *p*=0.1940;

160   control islets phase lag: 0.057sec ±0.005, *n*=3 islets from 1 mouse: *Robo βKO* islets phase lag:

161   0.083±0.01sec, *n*=3, *p*=0.0934; **Figure 4C-F**). Islets with sub-optimal coupling have been shown

162   to display full synchronization in Ca^{2+} oscillations, but with lower wave velocity[10]. Because there

163   is a trend toward slower wave velocity, these *Robo βKO* islets may still have sub-optimal

164   coupling due to architecture changes despite their fully synchronized Ca^{2+} oscillations.

165

8

166 ***Robo βKO* islets retain the ability to form gap junctions and have similar levels of**

167 **vascularization**

168   Besides a decrease in β cell-β cell homotypic contacts within the islet, a possible

169 explanation for the loss of synchronized whole islet Ca^{2+} oscillations in *Robo βKO* islets is that β

170 cells in *Robo βKO* islets no longer possess the gap junctions necessary for adequate electrical

171 coupling. Indeed, the phenotype described above is reminiscent of that observed in mice

172 heterozygous for a *Cx36* null allele[10,34]. To test whether *Robo βKO* mice form fewer gap

173 junctions between β cells, we measured the area of Cx36 protein immunofluorescence

174 normalized to islet area in *Robo βKO* and control islets (**Figure 6**). We observed no difference in

175 Cx36 immunofluorescence between *Robo βKO* islets and controls (**Figure 6B**), suggesting that

176 loss of synchronous intra-islet Ca^{2+} oscillations is not due to failure of gap junction formation in

177 β cells (control islets: 0.01±0.002 Cx36 signal/μm^2, *Robo βKO* islets: 0.01±0.001 Cx36

178 signal/μm^2, *n*=10-15, *p*=0.17 islets from 4 mice of each group).

179   Another possible explanation for the observed uncoupling of intra-islet Ca^{2+} oscillations

180 in *Robo βKO* islets is that β cell-β cell contact in *Robo βKO* is disrupted due to physical blocking

181 by non-endocrine tissue. To determine if other non-endocrine architectural changes within the

182 islet occur in *Robo βKO* mice we quantified the amount of matrix components secreted by

183 vessels as a surrogate for vasculature (laminin, and collagen IV) in *Robo βKO* and control islets.

184 In all cases we found no significant difference in area of vessel matrix components (**Figure 7**)

185 between *Robo βKO* and control islets, suggesting that interfering blood vessels are likely not the

186 cause of loss of whole islet synchronous Ca^{2+} oscillations (normalized laminin β1 area: control

187 0.3126±0.05 μm^2, *n*=10-12 islets from 8 mice; *Robo βKO* 0.3747±0.05 μm^2, *n*=10-12 islets from 8

188   mice; p= 0.3908; normalized Col IV area: control 0.1812±0.01 μm^2, *n*=10-12 islets from 4 mice;

189   *Robo βKO* 0.156±0.019, *p*=0.35).

190

191   **Discussion**

192   In this study, we provide evidence for the importance of islet architecture for proper

193   islet function *in vivo*. When islet architecture is disrupted while β cell maturity is retained in

194   *Robo βKO* mice, synchronized Ca^{2+} oscillations are perturbed in the *in vivo* islet. This is not due

195   to loss of Cx36, or change in amount of islet vascularization. *Robo βKO* β cells possess fewer

196   homotypic nearest neighbors than controls, suggesting a limited capacity to electrically couple

197   β cells across the islet. Taken together, these data indicate that islet architecture itself,

198   uncoupled from β cell maturity or availability of gap junction machinery is important for

199   coordinated insulin secretion between β cells.

200   Robo, and its ligand Slit, have been previously shown to affect Ca^{2+} oscillations in β cell

201   *in vitro*[35]. However, while it is possible that intrinsic β cell factors rather than the disrupted islet

202   architecture alone contribute to disruption of synchronized Ca^{2+} oscillations in *Robo βKO* islets

203   in our experiments, this is not likely the driving force. If this was the case, then we would expect

204   a highly penetrant asynchronous oscillation phenotype in *Robo βKO* islets, yet more than one-

205   third of *Robo βKO* islets analyzed showed highly synchronized Ca^{2+} oscillations. Instead, these

206   results suggest that deletion of *Robo* alone in β cells is not sufficient to abolish synchronicity.

207   Moreover, *Robo βKO* islets show a heterogeneous spectrum of disrupted architecture within

208   the same animal, with some islets displaying severe endocrine cell type intermixing while

209   others retain relatively normal architecture. Thus it is likely that islets with relatively normal

10

210 architecture correspond to the islets that display more synchronous Ca^{2+} oscillations. Moreover

211 phenotypic heterogeneity is likely not due to an incomplete deletion of *Robo* in a subset of

212 islets. This is evident by the fact the islets were detected during the Ca^{2+} imaging experiment by

213 the fluorescent labeling of β cells with the H2B-mCherry lineage-tracing reporter[31], which uses

214 the same Cre that is used to delete *Robo* in those β cells. Thus expression of H2B-mCherry

215 precludes inefficient Cre expression and recombination.

216   It also remains possible that other components of islet architecture besides endocrine

217 cell type sorting contribute to disruption in Ca^{2+} oscillations found in *Robo βKO* islets.

218 Specifically, while we have shown that the amount of vascularization between *Robo βKO* islets

219 and controls is similar, we cannot draw conclusions on whether the pattern of vessels is

220 unchanged. Further, it is possible that amount and patterning of innervation may vary between

221 *Robo βKO* and controls. This is particularly of interest because *Robo* has known roles in

222 angiogenesis and axon guidance, and thus could affect precisely how the islet is innervated and

223 vascularized[36].

224   Finally, our results may have implications towards directing islet architecture in the

225 pursuit of generating *bona fide* islets from stem cells *in vitro* for the treatment of diabetics.

226 Thus far, most efforts to create such stem cell derived islets have focused on creating

227 homogenous functionally mature β cells[37]. Such efforts have been largely successful in terms of

228 creating β cells that display insulin secretory profiles close to those of primary β cells[38]. Yet

229 despite their seeming resemblance to mature native β cells, islets made from stem cell-derived

230 β cells fail to fully match the function of isolated primary islets[37,38]. This has been partially

231 attributed to the fact that stem cell derived islets formed *in vitro* thus far have been simply

11

232   clusters of homogenous β cells, rather than an organized heterogeneous population of β cells

233   and other islet cell types[37]. Because of the importance of heterogeneous cell types in

234   controlling glucose homeostasis, it has become evident that achieving correct β cell

235   heterogeneity is needed to generate better islets *in vitro*[39]. However, it is likely that addition of

236   these cells without recapitulation of islet architecture will not generate islets with optimum

237   function and β cell coupling.

13

Materials and Methods

Animals

The experimental protocol for animal usage was reviewed and approved by the University of Wisconsin-Madison Institutional Animal Care and Use Committee (IACUC) under Protocol #M005221 and Protocol #M005333, and all animal experiments were conducted in accordance with the University of Wisconsin-Madison IACUC guidelines under the approved protocol. *Robo1$^\Delta$,2^{flx40}*, *Ins1-Cre*[41], *Urocortin3-Cre*[42] and *Rosa26-Lox-Stop-Lox-H2BmCherry*[43] mice were previously described. All mouse strains were maintained on a mixed genetic background. Control colony mates in all analyses were *Robo$^{+/+}$* with the either *Ins1-Cre or Ucn3-Cre*.

Immunofluorescence

Pancreata were fixed with 4% PFA at 4°C for 3h, embedded in 30% sucrose and frozen in OCT (Tissue-Tek). Pancreatic sections (10 μm) were stained using a standard protocol. The following primary antibodies and dilutions were used: guinea pig anti-Insulin (1:6, Dako, IR00261-2), mouse anti-Glucagon (1:500, Sigma G2654), rabbit anti-Glucagon (1:200, Cell Signaling 2760S), rabbit anti-Somatostatin (1:1000, Phoenix G-060-03), rabbit anti-Connexin36 (1:80, Invitrogen 36-4600), rabbit anti-Col IV (1:300, Abcam Ab656), rat anti-Laminin β1 (1:500, Invitrogen MA5-14657). The following secondary antibodies were used at 1:500: Donkey anti-Guinea Pig 594 (Jackson), Donkey anti-Guinea Pig 647 (Jackson), Donkey anti-Rabbit 488 (Invitrogen), Donkey anti-Rabbit 594 (Invitrogen), Donkey anti-goat 647 (Invitrogen), and Donkey anti-rat 488

14

279   (Invitrogen). Slides were imaged using a Leica SP8 Scanning Confocal microscope or a Zeiss Axio

280   Observer.Z1 microscope.

281

282   **RNA sequencing**

283   RNA was isolated from FACS sorted lineage-traced β cells[31] from control and *Robo βKO* mice

284   using phenol chloroform extraction (TRIzol). DNA libraries were generated using Takara's

285   SMART-Seq v4 Low Input RNA Kit for Sequencing (Takara, Mountain View, California, USA) for

286   cDNA synthesis and the Illumina NexteraXT DNA Library Preparation (Illumina, San Diego, CA,

287   USA) kit for cDNA dual indexing. Full length cDNA fragments were generated from 1-10ng total

288   RNA by SMART (Switching Mechanism at 5' End of RNA Template) technology. cDNA fragments

289   were fragmented and dual indexed in a single step using the Nextera kit's simultaneous

290   transposon and tagmentation step. Quality and quantity of completed libraries were assessed

291   using Agilent DNA series chip assay (Agilent Technologies, Santa Clara, CA) and Invitrogen Qubit

292   ds DNA HS Kit (Invitrogen, Carlsbad, California, USA), respectively. Each library was standarized

293   to 2nM. Cluster generation was performed on Illumina cBot, with libraries multiplexed for

294   1x100bp sequencing using TruSeq 100bp SBS kit (v4) on an Illumina HiSeq2500. Images were

295   analyzed using standard Illumina Pipeline, version 1.8.2.

296

297   **Intravital Imaging**

298   Mouse pancreata were exposed in anesthetized mice by making a small incision on the right

299   side of the mouse, and externalizing the tip of the pancreas. A glass dish was placed over the

300   exposed pancreas and the mouse was placed on a microscope stage with isoflurane anesthesia

15

301   for the remainder of imaging. Islets were identified on the surface of the pancreas by detecting

302   Histone H2BmCherry fluorescent nuclei labeled by β cell-specific lineage-tracing reporter[31].

303   Once islets were identified, mice were given injections of 1g/kg body weight glucose (30% in

304   saline) intraperitoneally. Blood glucose levels were monitored through tail vein bleeds. Once

305   the blood glucose reached ~300 mg/dL, GCaMP6s activity was identified using the microscope

306   eye piece. When imaging a time course of GCaMP6s intensity, a z-stack was set to 8 or 12 slices

307   each 8μm apart. Images were captured every 10 or 30 seconds respectively over 10 minutes at

308   a resolution of 512x512 pixels. After time courses were recorded, high resolution image z-stacks

309   were taken with 60 z planes taken 1μm apart or 8 z-planes taken 8μm apart at 1024x1024 pixel

310   resolution. For some images, rhodamine-dextran was injected retro-orbitally to mark the

311   vasculature of the islets *in vivo.*

312

313   **Gap junction and vasculature quantification**

314   Cx36 levels were quantified from images of islets co-stained with rabbit anti-Cx36 (Invitrogen)

315   and Guinea Pig anti-insulin antibody. Vasculature levels were quantified from images co-stained

316   with rat anti-Laminin β1 or rabbit anti-col IV and guinea pig anti-insulin. 8 Z-planes were taken

317   1μm apart on a Leica SP8 Scanning Confocal microscope using a 40x oil immersion objective

318   (Cx36) or 20X (vasculature). Threshold masks were made of both channels for each islets, and

319   the area of each staining was measured using FIJI's analyze particles functions. The area of gap

320   junctions, blood vessels (marked by their respective antibody) was divided by the area of insulin

321   for each islet. 10-14 islets were analyzed for *n*=2-8 mice for each genotype. Student's T-test was

322   performed to obtain *P* values.

16

323

Nearest Neighbor Analysis

324

325   β cells were identified using the lineage tracer *Rosa26-Lox-Stop-Lox-H2BmCherry* crossed to

326   *Ucn3-Cre* and tissue sections were stained with antibodies against glucagon and somatostatin

327   to identify α and δ cells respectively. The 3D Tissue Spatial Analysis Toolbox for Fiji[44] was used

328   to identify specific cell types using the above markers and to calculate the number of cell type

329   specific nearest neighbors from all identified endocrine cells. Analysis was performed on 9-11

330   islets from *n*=3 mice from each genotype.

331

Whole Organ Clearing and Imaging

332

333   Pancreata were fixed in 4% PFA for 3 hours at room temperature, then dehydrated stepwise in

334   methanol (33, 66%, and 100%) for 15 mins each step. Samples were then bleached using

335   MeOH:H_2O_2:DMSO bleaching buffer in a 2:1:3 ratio at RT for 24 hr, and then stored in methanol

336   overnight. Next, Samples were freeze-thawed for at least 5 cycles of 24 hour freeze then 2 hour

337   thaw in -80°C-RT to facilitate antibody penetration. Samples were then rehydrated stepwise

338   back to TBST (33%, 66%, 100%), at least 15 min/step, reducing the MeOH during each step.

339   Samples were then blocked in TBST with 10% donkey serum, 5% DMSO and 0.01% NaAz for 12-

340   24 hr at RT. Samples were then incubated with primary antibodies (Dako guinea pig anti-Insulin

341   and CST Rabbit anti-glucagon) in blocking buffer for 48 hr- 72 hr, then washed overnight in

342   TBST. Following wash, samples were incubated with secondary antibodies (594 anti-glucagon

343   and 647 anti-insulin) for 48-72 hr at RT, then washed overnight in TBST. Whole pancreata were

344   then mounted in low melting temp agarose for imaging. Whole pancreata were imaged using a

17

345   custom light sheet microscope. 2D images were collected in a 3 mm x 5 mm field of view every

346   10 um over a 5 mm volume to generate the 3D reconstruction. Imaris was used to assign

347   surface volumes to pancreas morphology, insulin surfaces, and glucagon surfaces by intensity

348   thresholding.

349

350   **Time Course Image Analysis**

351   All images were analyzed using previously published methods[45] with custom Matlab

352   (Mathworks) scripts. For activity analysis, images were smoothed using a 5x5 pixel averaging

353   filter. Areas without significant fluorescence were removed. Saturated areas were also removed

354   by limiting the area to intensity below the maximum value. Photobleaching was adjusted for by

355   removing any linear trend. Any islets with significant motion artifacts were removed or time

356   courses were shortened to the time over which no significant movement occurred

357   (displacement of <0.5 cell width). For the time course of each pixel in the image with significant

358   fluorescence, a peak detection algorithm was used to determine if the areas had peak

359   amplitudes significantly above background. A region was considered "active" if the

360   corresponding time course for each pixel had a peak amplitude >2.4x background. The fraction

361   of active area was calculated as the number of pixels detected as "active" across all z-planes,

362   normalized to the total number of pixels that showed significant fluorescence across all z-

363   planes that were not saturated. Islets with significant background fluorescence from spectral

364   overlap of channels were excluded from activity analysis because "inactive" cells were

365   indistinguishable from background and therefore total islet area could not be accurately

366   calculated. Coordination was determined based on coincident timing of identified peaks, where

18

367   areas were segmented by identified peaks occurring at similar time points. The cross

368   correlation of the time courses for two 5x5 pixel subregion was taken. If the correlation

369   coefficient was >0.75, then the two subregions were considered highly coordinated and merged

370   into a larger region. The coordinated area was calculated as the number of pixels in the largest

371   area of coordination across all z-planes normalized to the total number of pixels of the islet that

372   were determined to be 'active' for all planes. This analysis is based on previous analysis[45], but

373   adjusted for 3-dimensional data. Phase lag and wave propagation speed was determined as

374   in[10], where 2 regions were chosen manually within a coordinated area within the same z-plane.

375   The phase lag of these regions was calculated from a Fourier transform of each time course.

376   First the peak frequency was identified from the power spectrum, as generated from a Fourier

377   transform of each time course. At each peak frequency the phase was then calculated. The

378   phase lag was calculated from the difference in phase between each region, and converted into

379   a time lag according to ($dt=(1f)*tan-1(\varphi1-\varphi2)$), where $\varphi1-\varphi2$ is the phase difference, and f is

380   the sampling frequency of the time courses analyzed. Speed was calculated by dividing the

381   distance between the two regions by the time lag. For phase and speed analysis only islets with

382   >90% coordinated area was used. All statistical analysis was performed in Prism (Graphpad) or

383   Matlab. First a F-test was used to determine if variances were equal then a Student's t-test or

384   Welch t-test (for unequal variance) were utilized for determining whether activity,

385   coordination, phase lag and speed were significantly different. $p<0.05$ was considered

386   significant.

387 **Figure Legends**

388 **Figure 1: *Robo βKO* islets have fewer homotypic nearest neighbors than controls** (A)

389 Immunofluorescence images (left and middle panels) and cell connectivity maps generated by

390 nearest neighbor analysis (right panels) of control and *Robo βKO* islets. β cells (red), α cells

391 (green), and δ cells (blue) are denoted by nodes on the connectivity maps. A line the same color

392 as both nodes it connects denotes a homotypic interaction of that corresponding cell type. A

393 white line connecting two nodes denotes a heterotypic interaction between cell types. (B)

394 Probability of any homotypic cell-cell contact in *Robo βKO* islets vs controls (n=9-11 islets for 3

395 mice from each genotype; control 83.7%, *Robo βKO* 64.43%, p 0.0008). (C) Probability of β cell-

396 β cell contacts in *Robo βKO* islets *vs*. controls (n=9-11 islets for 3 mice from each genotype;

397 control 75.35%, *Robo βKO* 50.37%, p=0.01). (D) Probability of any heterotypic cell-cell contact in

398 *Robo βKO* islets *vs*. controls (n= 9-11 islets for 3 mice from each genotype; control 16.3%, *Robo*

399 *βKO* 35.57%, p=0.0008 (E). Probability of β cell- α cell contacts in *Robo βKO* islets vs controls

400 (n=9-11 islets for 3 mice from each genotype; control 11.21%, *Robo βKO* 25.99%, p=0.02). (B-E

401 Similar shaded points in graphs indicate islets from the same mouse).

402

403 **Figure 2: Control islets show highly synchronized whole islet Ca^{2+} oscillations** (A) High

404 resolution maximum intensity projection of a control islet *in vivo* in an *AAV8-RIP-GCaMP6s-*

405 injected mouse showing GCaMP6s in green, nuclear mCherry β cell lineage-tracing in red, and

406 collagen (second-harmonic fluorescence) in blue. (B) Stills over one oscillation period from

407 control islet in supplementary video 1, starting after blood glucose level reached ~300 mg/dL

408 from IP glucose injection. Video was recorded for 10 minutes with frames taken every 10

20

409   seconds. (C) Representative time courses of Ca^{2+} activity in 4 individual areas from control islet

410   in supplementary video 1 showing correlation over 98% of the active islet area. Time courses

411   are normalized to average fluorescence of individual area over time. Similar color indicates that

412   the time courses have a Pearson's correlation coefficient of ≥0.75 and matches the region of

413   coordination that is seen in D. (D) False color map of top five largest coordinated areas across z-

414   stack of control islet from analysis in C. Areas in grey are not coordinated. The color represents

415   a region of coordination with Pearson's Correlation Coefficient ≥0.75 of GCaMP6s activity. Cells

416   used in time courses in C are labeled.

417

418   **Figure 3: *Robo βKO* islets show uncoordinated whole islet Ca^{2+} oscillations** (A) High resolution

419   maximum intensity projection of a *Robo βKO* islet *in vivo* in an *AAV8-RIP-GCaMP6s*-injected

420   mouse showing GCaMP6s in green, nuclear mCherry β cell lineage tracing in red, and collagen in

421   blue. (B) Stills over one oscillation period from *Robo βKO* islet in supplementary video 2,

422   starting after blood glucose level reached ~300 mg/dL from IP glucose injection. Video was

423   recorded for 10 minutes with frames taken every 30 seconds. (C) Representative time courses

424   of Ca^{2+} activity in 4 individual areas from *Robo βKO* islet in supplementary video 2, showing

425   correlation of 43.6% of the active islet area. Time courses are normalized to average

426   fluorescence of individual area over time. Similar color indicates that the time courses have a

427   Pearson's correlation coefficient of ≥0.75 and matches the region of coordination that is seen in

428   D. (D) False color map of top five largest coordinated areas across z-stack of *Robo βKO* islet

429   from analysis in C. Areas in grey are not coordinated. The color represents a region of

21

430   coordination with Pearson's Correlation Coefficient ≥0.75 of GCaMP6s activity. Cells used in

431   time courses in C are labeled.

432

433   **Figure 4: Quantification of *Robo βKO* Ca^{2+} oscillation phenotype** *(*A) Largest fraction of area in

434   islet exhibiting coordinated Ca^{2+} oscillations for control and *Robo βKO* islets. (B) Fraction of

435   active islet area showing elevated Ca^{2+} activity for control and *Robo βKO* islets. (C) Phase lag of

436   islet from control and *Robo βKO* islets. Only islets with large coordination across islet (>90%

437   coordinated area) were used. (D) Speed across islets from control and *Robo βKO* islets. Only

438   islets with large coordination across islet (>90% coordinated area) were used. (E) Close up of

439   time-courses from islet in Figure 2, showing representative phase lag of Ca^{2+} waves of 2 cells in

440   the same z-plane. (F) Same as C but for Supplemental Figure 3.

441

442   **Figure 5*: Robo βKO* islets show heterogeneity in severity of architectural disruption** (A) Space

443   filling models generated from cleared 3x5mm sections of pancreatic tissue from control and

444   *Robo βKO* mice with insulin in red, glucagon in green, and auto-fluorescent surrounding tissue

445   in blue. Projections show surface views of islets with insulin channel shown as transparent in

446   order to visualize α cells on the adjacent side and the interior of the islet. (B) Close ups from

447   portions of the pancreatic tissue showing heterogeneity in architectural phenotype in *Robo βKO*

448   and number of α cells present in both control and *Robo βKO.*

449

450   **Figure 6: Amount of Cx36 gap junctions remains unchanged in *Robo βKO*** (A)

451   Immunofluorescent images showing Cx36 (gray or green) and insulin (red) in *Robo βKO* and

22

452   control islets. (B) Quantification of area of Cx36 staining normalized to islet area in *Robo βKO*

453   islets and controls showing no significant difference (*n*=10-12 islets for 4 mice per group,

454   *p*=0.17).

455

456   **Figure 7: Amount of vascularization remains unchanged in *Robo βKO* islets** (A) Representative

457   immunofluorescent staining of basement membrane marking vasculature (laminin and collagen

458   IV) showing similar amounts in *Robo βKO* and control islets (B) Quantification of area of staining

459   normalized to islet area showing no difference in amounts of basement membrane marking

460   blood vessels in *Robo βKO* compared to control islets.

461   **Supplemental Figures**

462   **Supplemental Video 1: Control islets show highly synchronized Ca^{2+} oscillations**. Intravital time

463   course video of an islet within the *in vivo* pancreas of a control β cell lineage traced mouse

464   infected with *AAV8-Ins1-GCaMP6s*. Lineage traced β cells are marked by mCherry in red and

465   GCaMP6s is shown in green. Mouse was injected IP with glucose, and video was recorded once

466   blood glucose levels reached ~300 mg/dL. Images were taken every 10 seconds through a Z-

467   stack of 8 slices each 8μm apart, over 10 minutes. Scale bar is 100μm. Time stamp shown in in

468   upper left corner shows time of image in min:sec.

469

470   **Supplemental Video 2: *Robo βKO* islets show unsynchronized Ca^{2+} oscillations.** Intravital time

471   course video of an islet within the *in vivo* pancreas of a *Robo βKO* β cell lineage traced mouse

472   infected with *AAV8-Ins1-GCaMP6s*, and retro-orbitally injected with rhodamine-dextran to

473   mark vasculature. Lineage traced β cells are marked by mCherry in red and GCaMP6s is shown

474   in green, and vasculature is shown in yellow. Mouse was injected IP with glucose, and video

475   was recorded once blood glucose levels reached ~300 mg/dL. Images were taken every 30

476   seconds through a Z-stack of 12 slices each 8μm apart, over 10 minutes. Scale bar is 100μm.

477   Time stamp shown in in upper left corner shows time of image in min:sec.

478

479   **Supplemental Video 3: Most *Robo βKO* islets show unsynchronized Ca^{2+} oscillations.** Intravital

480   time course video of an islet within the *in vivo* pancreas of a *Robo βKO* β cell lineage traced

481   mouse infected with *AAV8-Ins1-GCaMP6s*. Lineage traced β cells are marked by mCherry in red

482   and GCaMP6s is shown in green. Mouse was injected IP with glucose, and video was recorded

483 once blood glucose levels reached ~300 mg/dL. Images were taken every 10 seconds through a

484 Z-stack of 8 slices each 8µm apart, over 10 minutes. Scale bar is 100µm. Time stamp shown in in

485 upper left corner shows time of image in min:sec.

486

487 **Supplemental Video 4: A subset of *Robo βKO* islets retain synchronized Ca^{2+} oscillations**.

488 Intravital time course video of an islet within the *in vivo* pancreas of a *Robo βKO* β cell lineage

489 traced mouse infected with AAV8-Ins1-GCaMP6s. Lineage traced β cells are marked by mCherry

490 in red and GCaMP6s is shown in green. Mouse was injected IP with glucose, and video was

491 recorded once blood glucose levels reached ~300 mg/dL. Images were taken every 10 seconds

492 through a Z-stack of 8 slices each 8µm apart, over 10 minutes. Scale bar is 100µm. Time stamp

493 shown in in upper left corner shows time of image in min:sec.

494

495 **Supplemental Figure 1: *Robo βKO* islets retain β cell differentiation and maturity markers**

496 Volcano plot of differential gene expression from bulk RNA sequencing on lineage traced FACS

497 sorted β cells from *Robo βKO* and control mice showing no significant differential gene

498 expression of markers (*n*=2 mice from each group).

499

500 **Supplemental Figure 2: *Robo βKO* islets show uncoordinated whole islet Ca^{2+} oscillations** (A)

501 High resolution maximum intensity projection of a *Robo βKO* islet *in vivo* in an *AAV8-RIP-*

502 *GCaMP6s*-injected mouse showing GCaMP6s in green, nuclear mCherry β cell lineage-tracing in

503 red, and collagen (second-harmonic fluorescence) in blue. (B) Stills over one oscillation period

504 from *Robo βKO* islet in supplemental video 2, starting after blood glucose level reached ~300

505   mg/dL from IP glucose injection. Video was recorded for 10 minutes with frames taken every 10

506   seconds. (C) Representative time courses of Ca^{2+} activity in 4 individual areas from *Robo βKO*

507   islet in supplementary video 3, showing correlation of 50% of the active islet area. Time courses

508   are normalized to average fluorescence of individual area over time. Similar color indicates that

509   the time courses Similar color indicates that the time courses have a Pearson's correlation

510   coefficient of ≥0.75 and matches the region of coordination that is seen in D. (D) False color

511   map of top five largest coordinated areas across z-stack of *Robo βKO* islet from analysis in C.

512   Areas in grey are not coordinated. The color represents a region of coordination with Pearson's

513   correlation coefficient of ≥0.75 of GCaMP6s activity.

514

515   **Supplemental Figure 3: A subset of *Robo βKO* islets show coordinated whole islet Ca^{2+}**

516   **oscillations** (A) High resolution maximum intensity projection of a *Robo βKO* islet *in vivo* in an

517   *AAV8-RIP-GCaMP6s*-injected mouse showing GCaMP6s in green, nuclear mCherry β cell lineage

518   tracing in red, and collagen in blue. (B) Stills over one oscillation period from *Robo βKO* islet in

519   supplementary video 4, starting after blood glucose level reached ~300 mg/dL from IP glucose

520   injection. Video was recorded for 10 minutes with frames taken every 10 seconds. (C)

521   Representative time courses of Ca^{2+} activity in 4 individual areas from *Robo βKO* islet in

522   supplementary video 4, showing correlation of 98% of the active islet area. Time courses are

523   normalized to average fluorescence of individual area over time. Similar color indicates that the

524   time courses have a Pearson's correlation coefficient of ≥0.75 and matches the region of

525   coordination that is seen in D. (D) False color map of top five largest coordinated areas across z-

526   stack of *Robo βKO* islet from analysis in C. Areas in grey are not coordinated. The color

26

527   represents a region of coordination with Pearson's correlation coefficient of ≥0.75 of GCaMP6s

528   activity.
