30 **Summary:**
31
32 Golenberg et al. developed a citrullination-deficient zebrafish and demonstrated a role
33 for Padi2 in fin wound responses and regeneration. This work identified a distinct
34 population of cells within the regenerative notochord bead that exhibited wound-induced
35 histone citrullination.

36   **Abstract**

37   Calcium signaling is an important early step in wound healing, yet how these

38   early signals promote regeneration remains unclear. Peptidylarginine deiminases

39   (PADs), a family of calcium-dependent enzymes, catalyze citrullination, a post-

40   translational modification that alters protein function and has been implicated in

41   autoimmune diseases. We generated a mutation in the single zebrafish ancestral *pad*

42   gene, *padi2,* resulting in a loss of detectable calcium-dependent citrullination. The *padi2*

43   mutants exhibit impaired resolution of inflammation and regeneration after caudal fin

44   transection. Further, we identified a new subpopulation of cells displaying citrullinated

45   histones within the notochord bead following tissue injury. Citrullination of histones in

46   this region was absent and wound-induced proliferation was perturbed in Padi2-

47   deficient larvae. Taken together, our results show that Padi2 is required for the

48   citrullination of histones within a group of cells in the notochord bead, and for promoting

49   wound-induced proliferation required for efficient regeneration. These findings identify

50   Padi2 as a potential intermediary between early calcium signaling and subsequent

51   tissue regeneration.

59 **Introduction**

60   Humans have limited regenerative capacity, resulting in injury-induced scarring

61   and loss of tissue function in response to damage that can present significant clinical

62   challenges. Because mammalian wound repair occurs through similar stages as

63   regeneration in simple animal models (Yokoyama, 2008), regenerative animal models

64   may provide insight into the molecular signals that optimize mammalian wound healing.

65   After wounding, early signals activate a series of regenerative steps. The initial wound-

66   healing phase is defined by the migration and formation of the wound epithelium and

67   the recruitment of immune cells (Roehl, 2018). This is followed by the regenerative

68   program, including the formation of a blastema, a mass of stem-cell like cells that

69   mediate cell proliferation and restoration of damaged tissue (Whitehead et al., 2005).

70   Improper activation or regulation of these tightly controlled steps results in improper

71   regeneration. Although increased cytosolic calcium early in wound healing has been

72   linked to later regenerative proliferation (Globus et al., 1987; Lagoudakis et al., 2010;

73   Yoo et al., 2012a), there is limited understanding of how these early signals impact later

74   regenerative events.

75   An attractive candidate to link calcium increase with subsequent regeneration is

76   the family of calcium-dependent enzymes, peptidylarginine deiminases (PADIs or

77   PADs), which catalyze the deimination of a peptidyl-arginine to the neutrally-charged,

78   non-coded amino acid, citrulline (Vossenaar et al., 2003). These enzymes were recently

79   implicated in stem cell pluripotency because citrullination of histones and chromatin

80   modifiers can maintain pluripotency by promoting an open chromatin state, thereby

81   regulating gene expression (Christophorou et al., 2014; Wiese et al., 2019; Xiao et al.,

82   2017). Increased expression and activity of PAD enzymes is associated with

83   autoimmune disorders, cancers, and neurodegenerative disorders (Chang et al., 2009;

84   Gyorgy et al., 2006). While PADs have been studied in mammalian models, the

85   presence of multiple PAD isoforms and functional redundancies make it challenging to

86   dissect the role of citrullination in normal development and tissue repair.

87   Zebrafish, *Danio rerio*, have one highly-conserved copy of a *pad* gene, *padi2*,

88   that shares canonical mammalian PAD features, with conserved enzymatic activity and

89   calcium dependence. We generated a *padi2* mutant zebrafish line lacking detectable

90   calcium-dependent citrullination activity while displaying normal developmental but

91   impaired regenerative growth. This work provides insight into how calcium-dependent

92   citrullination may integrate early signals induced by injury to mediate subsequent tissue

93   repair.

94   **Results and discussion**

95   **Characterization of zebrafish peptidylarginine deiminase**

96   To examine the role of citrullination in zebrafish, we first characterized the

97   annotated zebrafish *pad* gene, *padi2*. A 7-exon transcript (203) and two 16-exon

98   transcripts with alternative start sites (201 and 202) are annotated (Fig S1 A). The 7-

99   exon transcript is predicted to lack the catalytic C-terminus, therefore, we focused on

100   cloning the transcripts with the two predicted alternative start sites and the shared exon

101   16 and identified two splice variants of *padi2*. These transcripts have different first

102   exons, but both splice variants share a complete exon 10, contrary to the genome

103   assembly predictions (Fig S1 A, arrows). Due to these discrepancies, these transcripts

104   are referred to here as 201a and 202 (Fig S1 A). These transcripts are highly conserved

105   with human PADs and share 55% amino acid identity and 69% similarity to human

106   PAD2 with conserved catalytic, substrate-binding and calcium-coordinating amino acids

107   (Fig S1 B) (Smith and Waterman, 1981). Using our newly generated polyclonal

108   antibody, immunoblotting showed a doublet at 75-80 kDa, providing further evidence for

109   two full-length zebrafish *padi2* splice variants (Fig S1 C, arrow). Notably, this antibody

110   did not detect a protein of equivalent size to the predicted transcript 203 (~35 kDA) (Fig

111   S1 C). The absence of this doublet with pre-immune serum and the detection of an

112   appropriately sized protein in *padi2*-201a mRNA-injected larvae demonstrates the

113   specificity of the antibody (Fig S1 D and E). This antibody also detected a large protein

114   species at roughly 200 kDa that is of unclear significance (Fig S1 C, asterisk).

115   To assess citrullination activity, we used a colorimetric *in vitro* citrullination

116   activity assay and detected citrullination activity with both bacterially expressed Padi2

117   variants (Fig 1 A) (Nakayama-Hamada et al., 2005). Mammalian PADs bind 5-6 calcium

118   ions for proper structure and activity, with essential roles for Ca1 and Ca2 (Arita et al.,

119   2004). Similarly, zebrafish Padi2 activity was also calcium dependent (Fig 1 A).

120   Furthermore, alanine point mutations of amino acids predicted to be necessary for Ca1

121   and Ca2 binding sites (Arita et al., 2004) impaired *in vitro* citrullination activity (Fig 1 B

122   and Fig S1 F). Mutation of the catalytic cysteine also abolished activity (Fig 1 B and Fig

123   S1 F). These data indicate that zebrafish Padi2 is a canonical PAD with similar function

124   as mammalian PAD enzymes.

125   **Generation of a *padi2* zebrafish mutant**

126   Padi2 is the ancestral protein of the mammalian PADs, with the broadest tissue

127   distribution and substrate specificity in mammals (Rebl et al., 2010; Vossenaar et al.,

128   2003). To characterize the role of citrullination in regeneration, we generated a

129   zebrafish *padi* mutant using CRISPR/Cas9 gene editing, targeting exon 7 of *padi2*, an

130   optimal target region preceding the catalytic amino acids and essential calcium binding

131   sites. The resulting CRISPR-generated product had a 20 base pair deletion (Fig 1 C

132   and D) and caused a predicted frameshift mutation resulting in an early stop codon.

133   Padi2 homozygous mutants ($padi2^{-/-}$) had reduced levels of *padi2* mRNA (Fig 1 E) and

134   loss of Padi2 protein (Fig 1 F and Fig S1 C) at 2 days post fertilization (dpf).

135   Additionally, we used the citrullination assay on lysates from whole 2 dpf larvae to

136   detect calcium-dependent citrullination activity. Importantly, $padi2^{-/-}$ zebrafish lysates

137   lacked citrullination activity, even in the presence of excess calcium (Fig 1 G), indicating

138   that Padi2 is likely the only protein with detectable citrullination activity in long pec

139   zebrafish larvae. Interestingly, although previous studies have indicated that

140   mammalian PAD1 and PAD6 are necessary for normal development and fertility

141   (Esposito et al., 2007; Kan et al., 2012; Zhang et al., 2016), we found that the Padi2-

142   deficient zebrafish did not display any gross morphological defects, had normal viability

143   and crossings of this mutant line following expected Mendelian ratios (Fig S2 A and B).

144   A homozygous incross produces viable and developmentally normal maternal-zygotic

145   embryos indicating a maternal *padi2* contribution is not necessary during early

146   embryonic development. To further address the role of citrullination in early

147   development, we detected citrullination activity in cleavage- and gastrula-stage embryos

148   and showed citrullination activity and Padi2 protein expression during both pre- and

149   post- maternal to zygotic transition in wild-type embryos activity in 1-2 hpf larvae. This

150   detected activity and protein was absent in the Padi2-deficient larvae (Fig 1 H and I).

151   These observations provide the first evidence that citrullination is not necessary for

152   broadly normal development in zebrafish.

153   The mammalian PAD2 is the predominant isozyme in skeletal muscle and

154   nervous system (Kubilus and Baden, 1983; Watanabe et al., 1988; Watanabe and

155   Senshu, 1989). To further characterize the mutant line, we examined the effects of the

156   mutation on muscle development in zebrafish. We visualized slow and fast-twitch

157   muscles in the trunk of 5 dpf larvae by staining for myosin heavy chain and F-actin. Both

158   skeletal muscle fibers in the *padi2*$^{-/-}$ larvae appeared morphologically comparable to

159   wild-type (Fig S2 C and D). To examine neuromuscular synapses in the trunk of 5 dpf

160   larvae, we immunostained for presynaptic vesicles (α-SV2) and acetylcholine receptors

161   (AChR, α-BTX) (Fig S2 E and F). Quantification of these puncta showed that *padi2*$^{-/-}$

162   larvae form more neuromuscular junctions than wild-type larvae (Fig S2 F). Previous

163   studies show that Padi2 is expressed in central synapses (Bayes et al., 2017) and that

164   PAD2 mice displayed behavioral defects (Falcao et al., 2019). These data suggest that

165   citrullination may regulate the development of synapses, providing an interesting

166   avenue for future investigation.

167   **Padi2 is required for efficient epimorphic regeneration**

168   To determine the role of citrullination in wound healing and regeneration, we

169   performed a tail transection of 2.5 dpf larvae through the notochord without wounding

170   the caudal vein, as described by Rojas-Munoz *et al.* 2009. *padi2* expression during

171   regeneration was determined at 24 hours post wounding (hpw) by qPCR analysis on

172   extracted wounded fin tissue compared to age-matched, unwounded tissue (3 dpf).

173   *padi2* was expressed in the affected tissue during regeneration and remained low in

174   *padi2^-/-* wounded fins (Fig S3 A). Regeneration of the fin was assessed 3 days post

175   wounding (dpw) by measuring the fin length from the blood circulation loop to the edge

176   of the fin along the notochord axis (Fig 2 A). Regrowth of the fin was impaired in the

177   Padi2-decifient larvae compared to wild-type cousins (Fig 2 B). Similar effects were

178   observed with transient morpholino depletion of *padi2* following a fin fold excision (Fig

179   S3 B). *padi2^-/-* larvae had a slight, but statistically significant, increase in their

180   developmental fin length at 5 dpf compared to wild-type cousins (Fig 2 C), indicating

181   Padi2 has different roles during fin development and regeneration. These findings

182   suggest that Padi2 is necessary for efficient tail fin regeneration, identifying a new role

183   for citrullination in wound repair. Interestingly, PAD activity and excessive citrullination

184   has previously been linked with poor wound healing in mice and chick embryos

185   (Coudane et al., 2011; Lange et al., 2011; Wong et al., 2015). It is possible that the

186   absence of a PAD4 orthologue in zebrafish may contribute to these differences and

187   their high regenerative capacity. Taken together, these findings support the idea that

188   tight regulation of citrullination activity is necessary for normal regeneration.

189   Furthermore, these results highlight the different mechanisms underlying developmental

190   and regenerative growth.

191   **Padi2 modulates leukocyte recruitment to a wound**

192   A hallmark of wound repair is leukocyte infiltration and subsequent resolution of

193   inflammation that can modulate wound healing (Wilgus et al., 2013). Citrullination has

194   been shown to affect the immune response in human disease (Li et al., 2010), with

195   direct evidence for deimination of leukocyte chemotactic cues (Loos et al., 2009; Proost

196   et al., 2008; Yoshida et al., 2014). To visualize leukocyte responses to a wound, we

197   compared *padi2^-/-* and wild-type cousin larvae with either labeled neutrophils

198   (*Tg(lyzc:H2B-mCherry)*) or macrophages (*Tg(mpeg1:H2B-GFP)*) and quantified

199   leukocyte numbers within the region posterior to the blood circulation loop (Fig 2 D-G).

200   Padi2-decifient larvae had a consistent increase in neutrophils at the wound at 6, 24,

201   and 48-hour post wounding (hpw) (Fig 2 E and F). This difference is not due to altered

202   total neutrophil numbers as total numbers in *padi2* mutants were not significantly

203   different than their wild-type cousins (Fig S3 C), although there was a small increase of

204   neutrophils in the unwounded fin (Fig S3 D). We also found a small increase in

205   macrophages at the wound site in *padi2^-/-* larvae, although this difference did not persist

206   and there was no change in total macrophage numbers (Fig 2 E, G and Fig S3 E, F).

207   Interestingly, macrophages displayed a localized aggregation around the notochord

208   bead at 6 hpw and 24hpw (Fig 2 E), suggesting a potential role for macrophages in the

209   notochord bead during wound healing. Taken together, these findings are consistent

210   with a recent report showing that lymph nodes from PAD2 knockout mice show an

211   increase in the expression of genes involved with leukocyte migration (Liu et al., 2018).

212   It is unclear if the persistent leukocyte infiltration is due to a failure of wound resolution

213   or due to a direct effect of citrullination on leukocyte signaling pathways. Citrullination of

214   chemokines have been reported to dampen inflammatory signaling (Loos et al., 2008;

215   Proost et al., 2008; Struyf et al., 2009), and the neutrophil chemokine, Cxcl8, and its

216   receptors, Cxcr1 and Cxcr2, regulate neutrophil forward and reverse migration in

217   response to a wound (Powell et al., 2017). Alternatively, citrullination of extracellular

218   matrix (ECM) components, such as collagen or fibronectin, affect cell migration (Shelef

219   et al., 2012; Sipila et al., 2014; Yuzhalin et al., 2018), and could potentially regulate

220   inflammation by altering the wound ECM.

221   **Wounding induces localized histone citrullination in the notochord bead**

222   We next considered whether wounding induces localized citrullination of histones

223   in larval zebrafish due to the reported role of citrullinated histones in maintaining

224   pluripotency (Christophorou et al., 2014; Wiese et al., 2019; Xiao et al., 2017). First, we

225   assayed for total histone H4 citrullination, using immunoblotting, in whole larvae lysates

226   treated *ex vivo* with calcium. Whole larvae lysate from wild-type larvae showed calcium-

227   dependent citrullination of histone H4 (H4cit3) that was not present in *padi2*$^{-/-}$ lysate (Fig

228   3 A), indicating that Padi2 mediates histone citrullination in zebrafish larvae. While

229   PAD4, but not PAD2 is required for histone citrullination in activated neutrophils in

230   mammals (Holmes et al., 2019), our data suggest that zebrafish Padi2 adopts some

231   functions of the later evolved PADs. Caudal fin transection results in increased

232   intracellular calcium at a wound (Yoo et al., 2012a) which may promote citrullination.

233   Visualization of histone H4 citrullination upon caudal fin amputation in wild-type

234   zebrafish revealed signal exclusively within a localized group of cells in the notochord

235   bead (Fig 3 B and C), a region previously described as the regeneration blastema

236   (Rojas-Munoz et al., 2009). Immunofluorescence microscopy revealed H4cit3 signal as

237   early as 1 hpw and this citrullination persisted up to 24 hpw (Fig 3 C). Histone H4

238   citrullination was diminished by 48 hpw, and was undetectable in the regenerated fin at

239   72 hpw (Fig 3 B and C). This histone H4 deimination is wound dependent as no signal

240   was observed in unwounded larvae (Fig S3 G).

241   To further characterize this structure, we used multiphoton microscopy to

242   understand the 3D localization of citrullinated histones within the context of the

243   wounded fin. Using second harmonic generation (SHG) to visualize the collagen fiber

244   network, in conjunction with H4cit3 immunostaining, we observed citrullinated histones

245   in a region devoid of collagen fibers at 6 hpw (Fig 3 D). The notochord bead containing

246   this signal formed posterior to the original wound axis demarcated by the end of the

247   collagen network. Labeling F-actin to visualize cell borders demonstrated that the

248   notochord bead is composed of multiple cells (Fig 3 E). The H4cit3 signal colocalized

249   with DAPI but only a subset of nuclei in this region were positive for histone

250   citrullination. Nuclei with histone citrullination can also be observed in cells outside the

251   notochord bead; it is possible that these cells move into this region from the notochord

252   (Fig 3 E, F). While mammalian PAD2 lacks a canonical nuclear localization signal,

253   evidence for nuclear localization and activity have been reported (Cherrington et al.,

254   2010; Cherrington et al., 2012; Zheng et al., 2019). Future experiments will be needed

255   to verify the mechanism by which zebrafish Padi2 translocates into the nucleus. Finally,

256   visualization of the epithelium using Tg*(krt4:EGFP)* revealed that histone citrullination

257   did not occur within epithelial cells (Fig 3 F). By 6 hpw, the wound epithelium has

258   already formed and encompasses the citrullinated cells and notochord bead (Fig 3 F).

259   Taken together, we have identified a new wound-induced structure within the notochord

260   bead comprised of a subpopulation of cells with citrullinated histones. Given the

261   previous work implicating citrullinated histones in pluripotency, this raises the intriguing

262   possibility that these cells represent a key signaling hub in regenerative growth. Future

263 work will be needed to identify which cells or signals are necessary to promote

264 citrullination only within this subpopulation of notochord bead cells.

265 Toward this goal, we found that wound-induced histone citrullination was absent

266 in *padi2*$^{-/-}$ larvae at 24 hpw (Fig 3 G). In the *padi2*$^{-/-}$ larvae, wounding did not induce

267 histone H4 citrullination in the notochord bead above unwounded levels, in contrast to

268 their wild-type cousins (Fig 3 G-I). Morphologically, both wild-type and Padi2-deficient

269 larvae formed similar sized notochord beads early after wounding (Fig 3 J). Previous

270 reports show that this region of cells act as a required wound-signaling center and

271 blastema structure that orchestrates regeneration (Rojas-Munoz et al., 2009; Romero et

272 al., 2018). Importantly, this population of cells with citrullinated histones were associated

273 with the blastema reporter, *Tg(lepb:EGFP)* (Kang et al., 2016) (Fig S3 H and I). Our

274 data indicate that citrullination is necessary for efficient regeneration and that a localized

275 population of cells within the blastema structure contains citrullinated histones. With a

276 known role for histone citrullination in stem cell maintenance, it is intriguing to speculate

277 that this population of cells with citrullinated histones has pluripotent features required

278 for efficient tissue repair by acting as a multipotent signaling center.

279 **Padi2-deficient larvae have impaired wound-induced proliferation**

280 An essential aspect of epimorphic regeneration is remodeling by wound-induced

281 apoptosis and proliferation (Gauron et al., 2013; Nechiporuk and Keating, 2002; Tseng

282 et al., 2007). We did not observe a significant change in wound-stimulated apoptosis in

283 *padi2* mutant larvae (Fig S3 J-L). We assayed cell proliferation using EdU incorporation

284 and found that mutant larvae had a greater number of EdU-positive cells within the

285 developing caudal fin than wild-type larvae (Fig 4 A and B), consistent with the

286   observed increase in *padi2*$^{-/-}$ developmental fin size (Fig 3 C). Upon wounding, wild-type

287   larvae had an almost 4-fold increase in proliferative cells within the regenerating fin

288   compared to the unwounded fins. By contrast, Padi2-decifient larvae exhibited impaired

289   induction of proliferation, with only a 2-fold induction of proliferation after wounding (Fig

290   4 C-E). Similarly, *padi2* morpholino knockdown resulted in decreased mitotic index at 24

291   hpw compared to control injected embryos (Fig S3 M and N). To further quantify

292   wound-induced proliferation, we focused on the dorsal region of the tail since much of

293   the developmental proliferation is localized to the ventral fin. In this dorsal region we

294   observed impaired proliferation in the *padi2*$^{-/-}$ larvae compared to wild-type cousins (Fig

295   4 F and G). These findings suggest opposing roles for Padi2 in developmental fin and

296   wound-induced proliferation, supporting the idea that these two processes have distinct

297   modes of regulation.

298   In summary, we identified a new role for citrullination in wound healing and

299   regeneration. Early calcium flux is a universal injury signal in organisms ranging in

300   complexity, and while there are many citrullination-independent calcium-induced wound

301   pathways (Niethammer, 2016), this work identifies one potential regenerative

302   mechanism downstream of early wound-induced calcium flux (Fig 4 H). We showed that

303   zebrafish Padi2 has conserved activity and calcium dependence, and that it is

304   necessary for calcium-mediated histone citrullination in zebrafish larval lysates. Padi2

305   appears to have opposing roles in developmental fin growth and regeneration with

306   respect to proliferation and tissue growth and is required for proper neutrophil response

307   to a wound. The identification of a new, localized population of cells with specifically

308   wound-induced, Pad2-dependent histone citrullination in the notochord bead suggests

309 that citrullination in this region may play a key role in orchestrating efficient regenerative

310 growth. The known role of histone citrullination in gene expression and pluripotency

311 suggests that this small population of cells represents a unique subset of blastemal

312 cells. A future challenge will be to characterize these cells further including analysis of

313 their gene expression profile to identify specific downstream effectors of this localized,

314 regulated histone citrullination. Moreover, this citrullination-deficient vertebrate model

315 provides a powerful tool for future studies to dissect the role of citrullination in

316 development, disease, and wound healing, and will aid in the identification of *in vivo*

317 Padi targets.

318

319 **Figure 1: Characterization of zebrafish Padi2.** (A) Citrullination activity of bacterially

320 expressed zebrafish Padi2 201a and 202 splice variants in total lysates with and without

321 calcium. Absorbance of light was measured and expressed as mean ($\pm$ SEM) relative

322 light units (RLU), normalized for protein level. Data represent 3 independent replicates.

323 (B) Citrullination activity of Padi2 201a and individual point mutations in calcium binding

324 and catalytic amino acids. Fold change of enzymatic activity is shown relative to wild-

325 type Padi2 201a. Data represent 2 independent replicates and wild-type values are also

326 represented in A. (C) Schematic of *padi2* gene with exon 7 gRNA sequence highlighted

327 for CRISPR/Cas9 mutagenesis. gRNA sequence in blue, PAM site in red. (D) Sequence

328 alignment of wild-type and *padi2*[-/-] 20 bp mutation in exon 7. MwoI restriction site for

329 genotyping highlighted in pink, predicted early stop codon highlighted in red. (E) RT-

330 qPCR of *padi2* exon5/6 on individual larvae from a *padi2*[+/-] incross. Data are from three

331 pooled independent replicates with the means and SEM reported and a one-sample t

332   test performed. (F) Representative western blot for zebrafish Padi2 and Actin from

333   pooled larvae (representative of 4 experiments). (G) Citrullination activity of pooled

334   zebrafish lysates expressed as relative light units (RLU). Data are from 3 independent

335   replicates with the means and SEM reported and an ANOVA performed. (H)

336   Citrullination activity of pooled embryo lysates during development. Fold change of

337   enzymatic activity is shown as a ratio of calcium-treated to no calcium for each

338   condition. Data are from 3 independent replicates. (I) Representative western blot for

339   zebrafish Padi2 and Actin from pooled zebrafish through stages of development

340   (representative of 3 and 2 experiments).

341

342   **Figure 2: Padi2 is required for proper regeneration and leukocyte recruitment.** (A)

343   Schematic of regeneration assay. Tail transections were performed through the

344   notochord (red dotted line) at 2.5 dpf. Fin lengths were measured from the blood

345   circulation to the end of the fin (blue solid line). (B) Representative bright field images of

346   regeneration at 3 dpw and quantification of regenerate fin length from 4 independent

347   replicates with n = 90 +/+, 95 -/-. (C) Representative images of 5 dpf developmental fins

348   and quantification of developmental fin length from 5 independent replicates with n =

349   109 +/+, 108 -/-. (D) Schematic of leukocyte quantification region (in blue) at a wound.

350   (E) Representative images of leukocytes at a wound at 6, 24, and 48 hpw visualized

351   with mCherry-labeled neutrophil nuclei (*Tg(lyzC:H2B-mCherry)*) and GFP-labeled

352   macrophage nuclei (*Tg(mpeg1:H2B-GFP)*). Fluorescence channel on the right, merge

353   with bright-field on the left. Macrophage localization to the periphery of the notochord

354   bead indicated with an arrow. (F) Quantification of number of neutrophil nuclei at a

355   wound from 3 independent replicates (6 hpw, n = 62 +/+, 57 -/-; 24 hpw, n = 50 +/+, 47 -

356   /-; 48 hpw, n = 63 +/+, n=65 -/-). (G) Quantification of number of macrophage nuclei at a

357   wound from 3 independent replicates (6 hpw, n = 61 +/+, 55 -/-; 24 hpw, n = 48 +/+, 44 -

358   /- ; 48 hpw n = 63 +/+, 57 -/-). All quantifications have lsmeans ($\pm$ SEM) reported with p

359   values calculated by ANOVA. Scale bars = 100 μm.

360

361   **Figure 3: Tail transection stimulates localized Padi2-dependent histone H4**

362   **citrullination.** (A) Representative western blot of *padi2$^{-/-}$* and wild-type whole larvae

363   lysates showing protein levels of: citrullinated Histone4 (H4cit3), total Histone4 (H4),

364   total Padi2 (zPadi2), and total Actin (Actin) (representative of 2 replicates). (B)

365   Representative images of H4cit3 antibody staining in tail transected fins at 20x

366   magnification. Merge images with bright-field are shown for orientation. Box denotes

367   region imaged at 60x magnification in (C) showing H4cit3 immunolabel alone. B-C,

368   Representative images from 3 independent replicates. (D-F) Representative

369   multiphoton microscopy enface (x,y view) and orthogonal (x, z view is below; y, z view is

370   to the right) sections of 6 hpw wild-type caudal fins labeled with H4cit3

371   immunofluorescence (green) in conjunction with either (D) SHG (white) or (E) DAPI

372   labeled nuclei (blue) and Rhodamine-phallodin labeled actin (magenta) or (F) DAPI

373   labeled nuclei (blue) and (T*g(krt-4:EGFP)*) expressing epithelium (magenta). Note in

374   (F) fluorophore tag for epithelium crosses into H4cit3 antibody channel at the setting

375   needed to detect the antibody signal. Arrow indicates nucleus with citrullinated histones

376   in the notochord region while arrowhead points to one example of a nucleus with

377   citrullinated histones in the notochord bead. For image presentation, section thickness

378   shown 2 μm for both x and y, 10 μm in z. Representative images from 2 independent

379   replicates. (G) Representative images of H4cit3 immunostaining in 24 hpw wild-type

380   cousin (left) and *padi2*-/- (right). (H) Quantification of H4cit3 signal area at the notochord

381   at 24 hpw and 3 dpf (no wound control). (I) Quantification of H4cit3 integrated density in

382   24 hpw larvae normalized to the average of 3 dpf for each genotype. Data are from 3

383   pooled independent (J) Quantification of the notochord bead area at 24 hpw from 3

384   pooled independent replicates. All quantifications have the lsmeans (±) SEM reported

385   and p values calculated by ANOVA (H-J: 24 hpw, n = 38 +/+, 41 -/-; 3 dpf n = 25 +/+, 25

386   -/-). Scale bars = 100 μm in B, G; 50 μm in C; 20 μm in D, E, F.

387

388   **Figure 4: Wound-induced proliferation is perturbed in Padi2-deficient larvae.** (A,C)

389   Representative images of 6-hour EdU pulsed larvae in (A) developmental, unwounded

390   or (C) 66 hpw fins. Merged images of EdU (green) and DAPI (white) on the left and

391   single EdU (white) image on the right. (B,D) Quantification of EdU-positive cells in the

392   fin. (E) Number of EdU-positive cells in the fin normalized to corresponding no wound

393   conditions. (F) Representative images of the dorsal half of 6-hour EdU-pulsed fins. (G)

394   Quantification of EdU-positive cells within the dorsal region of the fin. All data are from 3

395   pooled independent replicates with the lsmeans and SEM reported and p values

396   calculated by ANOVA (no wound, n = 39 +/+, 39 -/- ; 66 hpw n = 47 +/+, 47 -/-). Scale

397   bars = 100 μm. (H) A proposed model depicting how the early wound epithelial calcium

398   flux might activate (dashed arrow) Padi2 to catalyze citrullination events that, either

399   directly or indirectly (left question mark), regulate neutrophil (purple) recruitment to the

400   wound, possibly mediated by the Cxcl8 pathway or ECM modification. Concomitantly,

401   wound-dependent Padi2 citrullination of histones (green nuclei) within a subset of cells

402   in the notochord bead (pink) potentially stimulates, through yet to be determined

403   mechanisms (right question mark), regenerative proliferation.

404

405

406   **Materials and methods**
407   **Zebrafish maintenance and handling**

408   All protocols in this study were approved by the University of Wisconsin-Madison

409   Animal Care and Use Committee (IACUC). Adult zebrafish were maintained on a

410   14h:10h light/dark schedule. Fertilized embryos were transferred and maintained in E3

411   buffer at 28.5°C. This study utilized adult AB and NHGRI-1 (LaFave et al., 2014) fish

412   (obtained from the Zebrafish International Resource Center (ZIRC)) as well as

413   previously published transgenic lines *Tg(mpeg1:H2B-GFP)* (Miskolci et al., 2019),

414   *Tg(lyzc:H2B-mCherry)* (Yoo et al., 2012b), *Tg(krt4:EGFP)* (Yoo et al., 2012a), and

415   *Tg(lepb:EGFP)* (Kang et al., 2016).

416   **Zebrafish and Human PADI alignment**

417   Sequence alignments were performed using the EMBOSS Water pairwise

418   sequence alignment algorithm (Smith and Waterman, 1981). Predicted transcripts are

419   listed in Table 1. Transcript annotations are from GRCz10 with transcript 201a

420   indicating a sequence slightly divergent from GRCz10's transcript 201.

421   **Table 1. Annotated PADI transcripts used in this study.**

422

Generation of a padi2 mutant line and genotyping

424   Zebrafish CRISPR/Cas9 injections were performed as previously described in

425 our lab (LeBert et al., 2018; LeBert et al., 2015). Guide RNA (gRNA) for zebrafish Padi2

426 (ENSDARG00000044167) was designed using CHOPCHOP (Montague et al., 2014).

427 Exon 7 target sequence: GGGAACAGACACGCTGACGC

428   The pT7 gRNA was prepared as previously described (LeBert et al., 2018). The

429 gRNA and Cas9 protein (New England Biolabs) were injected into one-cell stage

430 NHGRI-1 embryos in a 2 nl volume consisting of ~50 ng/μl gRNA and ~300 nM Cas9.

431 To confirm genome editing by the gRNA, genomic DNA was extracted from 2 days post

432 fertilization (dpf) embryos, amplified using the primers listed below, and separated on a

433 3% MetaPhor gel (Lonza).

434 Padi2 F: CTGATACATGGCACAACCTACG

435 Padi2 R: GAAAACCAGCAAGCAGAGAAAGTT

436   Sequences of F0 mosaic cuts were confirmed by TOPO cloning (Invitrogen) and

437 sequencing. Clutches of larvae with confirmed CRISPR cuts were grown to adulthood.

438 Adult F0 CRISPR injected fish were screened for germline mutations by testing their

439 individual outcrossed offspring (2-5 dpf) using the primers listed above and Indel

440 Detection and Amplicon Analysis (IDAA) (Yang et al., 2015). Sequences were analyzed

441 using Peak Studio (McCafferty et al., 2012). Mutation sequence was confirmed by

442 TOPO cloning and sequencing.

443   Heterozygous *padi2* zebrafish were maintained by outcrossing the CRISPR

444   mutants to AB wild-type background zebrafish and genotyped by genomic DNA isolated

445   from fin clips and amplified using the primers listed above. PCR product was either

446   separated on a 2% agarose gel for 3 hours or digested overnight with MwoI (New

447   England Biolabs) and separated on an agarose gel to determine individual fish

448   genotypes. For experimental purposes, F2 or F3 heterozygotes were incrossed for the

449   generation of adult homozygous mutant and wildtype siblings. These adults were then

450   incrossed to produce *padi2$^{-/-}$* and wild-type clutches, referred to as cousins, which were

451   only used for experimentation and not for the maintenance of subsequent generations.

452   **qRT-PCR**

453   RNA and DNA were extracted from individual 2 dpf embryos from a *padi2+/-*

454   incross using TRIZOL (Invitrogen) following the manufacturer's protocol. Embryos were

455   genotyped using GoTaq (Promega) as described above and 2-3 embryos of each

456   genotype were used for cDNA production using Superscript III First Strand Synthesis

457   System with Oligo(dT) (Thermo Fisher Scientific). qPCR was performed using FastStart

458   Essential Green Master (Roche) and a LightCycler96 (Rocher). Primers for *padi2* and

459   *ef1a* are listed below. Data were normalized to *ef1a* using the ΔΔCt method (Livak and

460   Schmittgen, 2001) and represented as fold change over wild-type embryos.

461   For evaluation of *padi2* mRNA expression during wounding, incrosses of F3 or

462   F4 adult wild-type and *padi2$^{-/-}$* siblings were done to produce offspring cousins

463   homozygous for the *padi2* mutation or wild-type. Fin samples were amputated at the

464   line of the blood circulatory loop and 50-100 fins were pooled and flash frozen, with

465   equivalent sample sizes used per replicate. RNA was extracted from fin tissue from 24

466   hpw and unwounded, 3 dpf, larvae, as described above. Primers for *padi2* and *rps11*

467   (de Oliveira et al., 2013) are listed below. Data were normalized to *rps11* and

468   represented as fold change over wild-type, unwounded, age-matched control fins.

469   Padi2 exon5 qRT-PCR F: TAATGGCCATGGTGCAGTTC

470   Padi2 exon6 qRT-PCR R: ATGGTCCATTAGTGCGCAAC

471   Ef1a qRT-PCR F: TGCCTTCGTCCCAATTTCAG

472   EF1a qRT-PCR R: TACCCTCCTTGCGCTCAATC

473   Rps11 qRT-PCR F: TAAGAAATGCCCCTTCACTG

474   Rps11 qRT-PCR R: GTCTCTTCTCAAAACGGTTG

475   **Generation of zebrafish *padi2* clones and point mutations**

476   Padi2 splice variants were amplified with Pfu Turbo DNA polymerase (Agilent)

477   from cDNA using In-Fusion primers listed below. PCR products and a pCS2+8 vector

478   (Gokirmak et al., 2012) (Addgene) were digested with XbaI and BamHI (Promega) and

479   ligated at room temperature using Takara ligation kit for long fragments.

480   Padi2 cloning R, with XbaI: GGATCG TCTAGATTACAGCTCCAGGTTCCACC

481   Padi2 cloning F transcript 201: CGATCCGGATCCATGGTGTCCCGTCGATCTCTTAC

482   Padi2 cloning F transcript 202: CGATCCGGATCCATGAATGTTTCGCAGGAGC

483   Both cDNA transcripts were cloned into pTRCHisA vector (Invitrogen) for N-terminal

484   polyhistidine (his) tagging and expression in *E. coli* (BL21(DE3)pLysS Competent cells)

485   using primers listed below. Constructs were inserted into the vector cut with BamHI and

486   HindIII (Promega) using In-Fusion HD cloning kit (Clonetech). Point mutations were

487   made with complementary primers (listed below) in pTRCHisA-padi2 vectors using

488   QuikChange II Site-Directed Mutagenesis Kit (Agilent).

489   Catalytic C→A F: GTGAAGTTCACGCCGGGTCCAATGTTC

490   Catalytic C→A R: GAACATTGGACCCGGCGTGAACTTCAC

491   Ca1 binding Q→A F: ATCGCTGGATGGCGGATGAGCTTGAGTT

493   Ca1 binding E→A F: GGATGAGCTTGCGTTTGGTTACATTG

494   Ca1 binding E→A R: CAATGTAACCAAACGCAAGCTCATCC

495   Ca1 binding E→A F: TTTCGGTAATCTGGCGGTCAGTCCACCA

496   Ca1 binding E→A R: TGGTGGACTGACCGCCAGATTACCGAAA

497   Ca2 binding D→A F: TGTTGTCCTGGCTTCTCCTCGTGAT

498   Ca2 binding D→A R: ATCACGAGGAGAAGCCAGGACAACA

499   **Antibody production and western blotting**

500   The anti-zebrafish Padi2 antibody was generated in rabbits using combined full

501   length 201a and 202 variants fused to 6x poly-histidine in the pTRCHisA vector. Each

502   immunogen was purified from BL21 *E. coli* lysates using a nickel-nitrilotriacetic acid

503   superflow resin (Qiagen) then combined and sent for anti-sera production (Covance).

504   For western blotting, 50-100 ~2 dpf or 5 dpf larvae were pooled and deyolked in

505   calcium-free Ringer's solution via gentle disruption with a p200 pipette. Lysates from 2

506   hpf and 7 hpf larvae were not deyolked; samples were instead dechorionated on a petri

507   dish coated with 2% agarose and then rinsed with PBS. Larvae were washed twice with

508   phosphate-buffered saline (PBS) and stored at -80°C until samples were lysed by

509   sonication in 20mM Tris pH 7.6, 0.1% Triton-X-100, 0.2 mM phenylmethylsulfonyl

510   fluoride (PMSF), 1 µg/mL Pepstatin, 2 µg/mL Aprotinin, and 1 µg/mL Leupeptin at 3 µL

511   per larvae while on ice and clarified by centrifugation. Protein concentrations were

512   determined using a bicinchoninic acid protein assay kit (Thermo Fisher Scientific),

513   according to the manufacturer's instructions. Equal amounts of total protein were loaded

514   on 6-20% gradient SDS-polyacrylamide gels and transferred to nitrocellulose. For

515   citrullination analysis by western of whole zebrafish lysates, methods for the

516   citrullination colorimetric assay were followed, as described below, with the addition of

517   dilution buffer in place of BAEE (N_α-Benzoyl-L-arginine ethyl ester hydrochloride in 100

518   mM Tris pH 7.4). The reaction was stopped after 90 minutes by boiling samples in SDS-

519   PAGE sample buffer. zPadi2 rabbit anti-serum was used at 1:500 dilution, anti-Histone

520   H4 (citrulline 3) (EMD-Millipore) at 1:50, anti-actin (ac15; Sigma) at 1:1000, and anti-

521   Histone H4 (EMD-Millipore) at 1:1000. Western blots were imaged with an Odyssey

522   Infrared Imaging System (LI-COR Biosciences).

523   ***padi2* mRNA re-expression**

524   *padi2*-201a cloned into pCS2+8 (described above) was linearized using NotI

525   restriction digest and RNA was *in vitro* transcribed using the mMessage mMachine Sp6

526   kit (Ambion). RNA was cleaned up using an RNeasy Minikit column (Qiagen) and

527   injected into single cell embryos (3nl of 100ng/ul). Embryo lysates were collected as

528   described for western blotting at 2dpf and 5dpf.

529   ***In vitro* citrullination colorimetric assay**

530   Zebrafish Padi2 constructs and point mutations were expressed in BL21 *E. coli*

531   cells. Lysates were prepared on ice by sonication in 20mM Tris pH 7.6, 0.1% Triton-X-

532   100, 0.2 mM phenylmethylsulfonyl fluoride (PMSF), 1 μg/mL Pepstatin, 2 μg/mL

533   Aprotinin, and 1 μg/mL Leupeptin and clarified by centrifugation. Bacterial lysates were

534   aliquoted and frozen at -80°C. Lysates from zebrafish larvae were prepared as

535   described above for western blotting and used at equivalent amounts. Assay performed

536   as previously described (Nakayama-Hamada et al., 2005). In short, 12.5µL lysate was

537   incubated with 12.5 µL 4X reaction buffer (400 mM Tris pH 7.4, ± 80 mM $CaCl_2$, 20 mM

538   DTT), 12.5 µL 80 mM BAEE (N_α-Benzoyl-L-arginine ethyl ester hydrochloride in 100 mM

539   Tris pH 7.4), 12.5 µL dilution buffer (10 mM Tris pH 7.6, 150 mM NaCl, 2mM DTT) for 1

540   hour at 37°C. Reaction was stopped by the addition of 33 µM EDTA final concentration.

541   Reactions were diluted 1:10 for an 8 mM BAEE final concentration and 50 µL aliquots

542   were done in triplicate in a 96-well plate. 150 µL colorimetric buffer (composed of 1 mL

543   buffer A (80 mM diacetyl monoxime, 2 mM thiosemicarbazide) and 3 mL buffer B (3 M

544   phosphoric acid, 6 M sulfuric acid, 2 mM ammonium iron (III) sulfate)) were added to

545   each well and incubated at 95°C for 15 minutes, absorption was read at 540 nM.

546   Relative light units were normalized to western blot densitometry using Odyssey

547   Infrared Imaging System (LI-COR Biosciences).

548   **Morpholino injections**

549   Morpholino oligonucleotides (Genetools) were designed to the intron1/exon2

550   border of *padi2*. Morpholinos were resuspended in water to a final concentration of 1

551   mM. Morpholinos were diluted to a final concentration of 100 µM and 3 nl injection mix

552   was injected into one-cell stage embryos which were subsequently maintained at

553   28.5°C. Morpholino sequences used: *padi2* MO: 5'-

554   GAGCACATCTGGAATGGGAATATAT; control MO: 5′-

555   CCTCTTACCTCAGTTACAATTTATA-3′.

556   **Regeneration assays**

557   For larval regeneration assays, incrosses of F3 or F4 adult wild-type and *padi2^-/-^*

558   siblings were done to produce offspring cousins homozygous for the *padi2* mutation or

559   wild-type. Dechorionated larvae were transferred to 35 mm milk-coated plates. Larvae

560   were washed twice in E3 and wounded in a final 0.24 mg/mL tricaine (ethyl 3-

561   aminobenzoate, Sigma)/E3 solution. Tail transections were performed on ~2.5 dpf

562   larvae with a surgical blade (feather no 10) roughly four vacuolated cells from the

563   posterior end of the notochord. Larvae were again washed 3 times with E3 and allowed

564   to regenerate for 3 days post-wounding (dpw), at which point larvae were fixed with 4%

565   paraformaldehyde (PFA; Sigma-Aldrich) in PBS at 4°C overnight. Fins were imaged on

566   a Zeiss Zoomscope (EMS3/SyCoP3; Zeiss; 1x Plan-NeoFluor Z objective) with an

567   Axiocam Mrm CCD camera using ZEN pro 2012 software (Zeiss). Regenerate length

568   was measured from the edge of the blood vessel to the caudal edge of the tail fin using

569   the FIJI image analysis software (Schindelin et al., 2012)). Unwounded, 5 dpf larvae fin

570   lengths were measured as a developmental control. Fin transections were performed on

571   MO injected larvae similarly to as described above with amputation adjacent to the

572   notochord, without causing damage to the notochord. Regenerated fins and

573   developmental controls were measured from the caudal tip of the notochord to the

574   caudal edge of the tail fin.

575   **Immunofluorescence, microscopy and analysis**

576   Images always shown with anterior to the left.

577   <u>Neuromuscular labels</u>

578   Immunostaining was performed on cousin offspring from incrossed adult F2 wild-

579   type siblings and incrossed *padi2^-/-^* sibling zebrafish. 5 dpf larvae were fixed in 4% PFA,

580 0.125 M sucrose, and 1X PBS overnight at 4°C. For detection of slow muscles, larvae

581 were washed 3 times with 0.1% PBS-Tween20 and incubated in 0.1% w/v collagenase

582 type 1A (Sigma) in PBS at 37°C for 1.5 hours, followed by 3 washes in PBSTD (0.3%

583 TritonX, 1% DMSO in PBS). Larvae were blocked for 2 hours at room temperature (RT)

584 in PBSTD with 2% BSA and 4% goat serum. Monoclonal mouse anti-myosin heavy

585 chain antibody (F59) (DSHB) (Miller et al., 1985) was used at 1:20 in block buffer and

586 incubated overnight in 4°C. Larvae were washed five times in PBSTD and secondary

587 Dylight 488 donkey anti-mouse IgG antibody (Rockland Immunochemicals) was used at

588 1:250 in block buffer overnight at 4°C. Final five washes were done in PBSTD. Images

589 were acquired on a spinning disk confocal (CSU-X; Yokogawa) on a Zeiss Observer Z.1

590 inverted microscope and an EMCCD evolve 512 camera (Photometrics) with a Plan-

591 Apochromat NA 0.8/20x air objective and collected as z-stack of 1 μm optical sections

592 at 512x512 resolution. Images were z-projected with using Zen 2.3 lite software (Zeiss).

593   For visualization of fast muscle, fixed fish were washed with PBS 3 times

594 followed by three washes in PBS with 0.1% Tween20. Larvae were permeabilized with

595 PBS 2% PBSTx (20% Triton-X-100 in 1X PBS) for 1.5 hours with gentle rocking. Fish

596 were then incubated with Rhodamin-phalloidin (Invitrogen) diluted 1:100 in 2% PBSTx

597 at 4°C overnight. Fish were rinsed in fresh 2% PBSTx followed by several washes in

598 0.2% PBSTx. Imaging was performed on the spinning disk microscope with a Plan-

599 Apochromat NA 0.8/20x air objective (centered on cloaca) with 1 μm optical sections.

600   For neuromuscular junction visualization, fix was washed off with three PBS

601 washes. The skin was peeled with fine forceps (Dumont #55 dumostar, Fine Science

602 Tools) starting above the swim bladder and removed down to the fin. Skinned larvae

603   were incubated in 0.1% w/v collagenase type 1A at RT for 15 minutes with gentle

604   rocking followed by three washes in PBS. For detection of acetylcholine receptors

605   (AChR), larvae were incubated for 30 minutes at RT 10 µg/ml Alexa 594 conjugated a-

606   bungarotoxin (Thermo Fisher Scientific) diluted in incubation buffer (IB: 0.1% sodium

607   azide, 2% BSA, 0.5% Triton-X-100 in PBS, pH7.4). Embryos were rinsed three times in

608   IB.Mouse anti-synaptic vesicle glycoprotein 2A antibody (SV2) (DSHB) (Buckley and

609   Kelly, 1985) was used at 1:50 in IB overnight at 4°C. Larvae were washed 5 times in IB

610   and incubated with secondary Dylight 488 donkey anti-mouse IgG antibody (Rockland

611   Immunochemicals) at 1:250 in IB for 4 hours at RT or 4°C overnight. Final washes were

612   done in IB before imaging on a spinning disk microscope with an EC Plan-NeoFluaR NA

613   0.75/40x air objective (Zeiss) (centered around the cloaca with 2x1 tile images and 1 µm

614   optical section z-stacks). To quantify colocalization of signal, maximum intensity

615   projections were analyzed in FIJI using the plugin ComDet v3.7 for spot localization

616   (https://github.com/ekatrukha/ComDet/wiki). Particles were threshold as approximate

617   size being 5 pixels, intensity threshold for SV2 between 4-5 and α-BTX between 2-3

618   and a 6 pixel max distance between particles.

619   Histone citrullination

620   Immunostaining was performed on offspring cousins from incrossed adult F3

621   wild-type siblings and incrossed $padi2^{-/-}$ siblings. To identify histone citrullination, larvae

622   were fixed in a solution of 1% NP-40, 0.5% Triton-X, and 1.5% PFA in PBS at 4°C

623   overnight. The following day fix was replaced with a block solution of 2.5% BSA, 0.5%

624   Tween-20, 5% goat serum in PBS. Samples were blocked for at least 2.5 hours at room

625   temperature followed by the addition of poly-clonal rabbit anti-histone H4 (citrulline 3)

626   antibody (EMD Millipore) used at 1:100 and incubated overnight at 4°C. For time course

627   experiments, samples were kept in block at 4°C until the final sample was prepared, at

628   which time all samples were blocked at room temperature before the addition of the

629   primary antibody. Samples were washed 3 times in PBS at room temperature for 5

630   minutes each and secondary Dylight 488 donkey anti-rabbit (Rockland

631   Immunochemicals) or Alexa Fluor 568 goat anti-rabbit IgG antibodies (Invitrogen) were

632   used at 1:250 in block buffer overnight at 4°C. When indicated, Rhodamine-phalloidin

633   (Invitrogen) and 10 mg/mL DAPI (4',6-diamidino-2-phenylindole; Sigma) were added

634   with secondary antibodies at 1:100 and 1:10,000 dilutions, respectively. Finally, 4

635   washes were done in PBS. Images were acquired on a laser-scanning confocal

636   microscope (FluoView FV1000; Olympus) with an NA 0.75/20x or PLANAPO NA

637   1.45/60x oil objective and FV10-ASW software (Olympus). 20x images used for

638   quantification were acquired as Z-stacks with 25, 1 um optical slices at 640x640

639   resolution. Alternatively, images were acquired using multiphoton microscopy. For this,

640   caudal fins of fixed, PTU-treated, labeled larvae were removed from the trunk with a

641   scalpel blade (Feather #15) then imaged in a 50 mm coverglass (#1.5) bottom dish

642   (MatTek, Ashland MA) in PBS, as previously described (LeBert et al., 2016; LeBert et

643   al., 2015). A second coverslip over the glass bottom depression minimized sample

644   movement. The fins were imaged on a custom-built multiphoton microscope (Conklin et

645   al., 2011; LeBert et al., 2016) at the Laboratory for Optical and Computational

646   Instrumentation using a 40X long working distance water immersion lens (1.2 NA,

647   Nikon, Melville NY). All signals were detected sequentially using a H7422P-40 GaAsP

648   Photomultiplier Tube (PMT) (Hamamatsu, Japan). The backwards SHG signal was

649   collected with the multiphoton source laser (Chameleon UltraII, Coherent Inc., Santa

650   Clara, CA) tuned to 890 nm, with a 445/20 nm bandpass emission filter (Semrock,

651   Rochester NY). The fluorescent signal from H4cit3 antibody was collected using a either

652   a 520/35 nm bandpass emission filter (Semrock) for the Dylight 488 donkey anti-rabbit

653   secondary antibody (Rockland Immunochemicals) or a 615/20 nm bandpass emission

654   filter (Semrock) for the Alexa Fluor 568 goat anti-rabbit secondary antibody (Invitrogen).

655   The 615/20 emission filter was used to collect the fluorescent signal from the

656   Rhodamine-Phalloidin while the 520/35 nm emission filter was used to detect the

657   krt4:EGFP and lepb:EGFP fluorescence. DAPI fluorescence was excited with the laser

658   tuned to 740 nm and the emission collected using the 445/20 filter. Brightfield images

659   were simultaneously collected using a separate photodiode-based transmission

660   detector (Bio-Rad, Hercules CA). Data were collected as z-stacks with optical sections 2

661   microns apart, at 512 x 512 resolution.

662   Mitotic index

663   For evaluation of cells undergoing mitosis, 24 hpw and 3 dpf MO-injected larvae

664   were fixed with 1.5% PFA in 0.1M PIPES, 1.0 mM, 2 mM EGTA overnight at 4°C and

665   immunolabeled with phosphorylated histone H3 (serine10) antibody (Millipore). To

666   remove fixation solution, larvae were washed with PBS three times and placed in

667   methanol at -20°C overnight. Samples were rehydrated in subsequent 5 minute washes

668   at ratios of 2:1, 1:1, 1:2 methanol:PBSTx (PBS with 0.2% Triton-X), and a final PBSTx

669   wash. Larvae were incubated in 0.15 M glycine in PBS for 10 minutes at room

670   temperature followed by 3 PBSTx washes. Fish were blocked in 1% BSA in PBSTx for 1

671   hour at room temperature. Phosphorylated histone H3 (serine10) antibody diluted 1:300

672   in block was incubated overnight a 4°C. Samples were washed for 15-30 minutes in

673   block, twice in PBSTx, and another wash in block. Incubation with Dylight donkey anti-

674   rabbit 488 secondary was used, followed by four washes in PBSTx. Samples were

675   imaged and quantified on the laser-scanning confocal microscope with a 20x lens, as

676   described above.

Leukocyte Imaging

678       $padi2^{+/-}$ adults were crossed to AB wild-type zebrafish labeled with macrophage

679   nuclei (*Tg(mpeg1: H2B-GFP)*) or neutrophil nuclei (*Tg(lyzc:H2B-mCherry)*)) and

680   subsequently incrossed to produce homozygous, fluorescently labeled adults.

681   Experiments were performed on wild-type cousins and $padi2^{-/-}$ larvae resulting from

682   incrossed adult transgenic siblings. Wounding was performed as described above and

683   larvae were fixed with 1.5% PFA in 0.1 M PIPES (Sigma-Aldrich), 1 mM $MgSO_4$ (Sigma-

684   Aldrich), and 2 mM EGTA (Sigma-Aldrich) overnight at 4°C. Wounds were imaged on a

685   Zeiss Zoomscope, as above. Leukocyte numbers were counted by hand in the region

686   past the blood circulatory loop. Whole larvae images were acquired on a spinning disk

687   confocal (CSU-X; Yokogawa) on a Zeiss Observer Z.1 inverted microscope and an

688   EMCCD evolve 512 camera (Photometrics) with a Plan-Apochromat NA 0.8/20x air

689   objective (5 μm optical sections, 5x1 tiles, 2355x512 resolution).

EdU and apoptosis labeling

691   Immunostaining was performed on offspring "cousins" from incrossed adult F3

692   wild-type siblings and incrossed $padi2^{-/-}$ siblings. Proliferation in the fin was measured

693   using Click-iT Plus EdU Imaging Kit (Life Technologies). Larvae were incubated in 10

694   μM EdU (5-ethynyl-2'-deoxyurdine) solution in E3 for 6 hours with slight agitation.

695   Wounded fish were incubated from 60-66hpw along with age matched unwounded

696   controls. Larvae were fixed in 4% PFA in PBS overnight at 4°C and stored in methanol

697   at -20°C until staining. Staining protocol was conducted according to manufacturer's

698   instructions. EdU-stained larvae were also incubated with rabbit anti-active Caspase3

699   antibody (BD Biosciences) at 1:200 in block (PBS, 1% DMSO, 1% BSA, 0.05% Triton-X,

700   1.5% goat serum) followed by incubation with Alexa 550 goat anti-rabbit secondary

701   antibody and 0.01 mg/mL DAPI (Sigma). Immunofluorescence images were acquired on

702   a spinning disk confocal (CSU-X; Yokogawa) on a Zeiss Observer Z.1 inverted

703   microscope with an EMCCD evolve 512 camera (Photometrics) and a Plan-Apochromat

704   NA 0.8/20x air objective, as Z-stacks, 3 µm optical sections, and with 512x512

705   resolution.

706   **Image analysis/processing**

707   Image analysis was performed on FIJI. For experiments where fluorescence

708   intensity was quantified, no adjustments were made to the images prior to analysis. For

709   Histone H4cit3 analysis, a region of interest 92 x 93 microns was centered around the

710   notochord, as determined by the corresponding bright-field image. Immunostained

711   images were z-projected as a maximum intensity projection and the integrated density

712   in the region of interest (ROI) was determined. Images were thresholded using the

713   threshold plugin using auto-thresholding with the "Intermodes" method in Fiji (Prewitt

714   and Mendelsohn, 1966) and the total area within the ROI was determined for particles

715   larger than 8 pixels. For presentation purposes, images were processed to remove

716   background using despeckling. Notochord bead area was determined in FIJI by

717   outlining this structure as determined by examination of the optical bright-field slices.

718   Total neutrophil numbers were determined using Imaris (Bitplane) with the spots

719   function as defined by a 10 µm diameter in the XY plane and a Z-diameter of 20 µm.

720   Total macrophage numbers were counted by hand using Z-projected images in Zen 2.3

721   lite software. For total leukocyte quantifications, leukocytes within the yolk sac and heart

722   were excluded.

723   For spatial assessment of nuclei with citrullinated histones, three dimensional

724   reconstructions and slices were constructed using Imaris (Bitplane, Oxford Instruments,

725   UK). Videos of z-stack scans and 3D rotations were made in Imaris, annotated in FIJI

726   using "Annotation_to_overlay1.3" plugin

727   (https://www2.le.ac.uk/colleges/medbiopsych/facilities-and-services/cbs/AIF/software-

728   1/imagej-macros#Annotation) and converted to MP4 using HandBrake (v1.2.2) software

729   (The HandBrake Team, https://handbrake.fr/).

730   For EdU analysis, images were 3D reconstructed using Imaris software

731   (Bitplane). The number of EdU-positive cells were quantified in the fin region posterior

732   of the blood circulatory loop with the spots function as defined by an XY-diameter of 7

733   µm and a Z-diameter of 14 µm. The level of apoptosis activation at the wound was

734   determined by outlining the fin past the blood circulation using the corresponding bright-

735   field image. In FIJI, total threshold area for active-Caspase3 signal in the wound was

736   determined using the threshold plugin in Fiji by auto-thresholding with the "Yen Dark"

737   method (Yen et al., 1995) for particles larger than 3 pixels.

738   **Statistical analysis**

739   For all statistical analyses, at least three independent replicates were conducted.

740   For data in Fig 1 G, analysis was done using one-way ordinary analysis of variance

741   (ANOVA) with a Holm-Sidak's multiple comparisons test. To examine mutant survival,

742   Mendelian ratio was confirmed for both larvae and adult offspring from a heterozygous

743   incross by Chi-squared tests. For all other quantitative experiments, data were pooled

744   from the independent replicates and results were summarized in terms of least-squared

745   adjusted means (lsmeans) and standard errors (Vincent et al., 2016). Results were

746   analyzed using ANOVA with a Tukey's multiple comparisons test. Graphical

747   representation shows individual data points color coded to reflect replicates. Statistical

748   analysis and graphical representations were done using R version 3.4 and GraphPad

749   Prism version 6.

750

751   **Summary of supplemental material**.

752   Supplemental material includes additional data characterizing the zebrafish Padi2

753   transcripts and proteins (Fig. S1), additional characterization of the *padi2* mutant (Fig

754   S2), and additional non-wound phenotypes observed in the mutant and supporting

755   morpholino data (Fig. S3). We also include 6 videos that characterize the 3 dimensional

756   context of the citrullinated histones post injury.

757

758   **Supplemental material**

759   **Figure S1: Characterization of zebrafish Padi2.** (A) Schematics of *padi2* transcripts,

760   with exons represented by solid boxes and introns by connected lines (slashes indicate

761   shortening of relative length for display purposes). Left, list of the corresponding last 7

762   digits of Ensembl ID from GRCz11 and GRCz10 genome assemblies (full Ensemble IDs

763   listed in materials and methods). Right, list of the names based on GRCz10 used to

764   reference the transcripts. Cloned transcripts discussed in this paper are in green and

765   arrows highlight exon 10. (B) Full amino acid sequences of human PAD2 and predicted

766   zebrafish Padi2 splice variants (201a and 202). Amino acids are highlighted (as

767   indicated in key) to demonstrate calcium binding, catalytic residues, and substrate-

768   binding residues. Black arrow heads indicate amino acids referred to in Fig 1 B and S1

769   F. (C) Full western blot (from Fig 1 F) of pooled larvae probed with antibodies against

770   zebrafish Padi2 and Actin. Wild-type and *padi2*$^{-/-}$ lysates were probed. Arrow

771   demonstrates expected size of Padi2 transcripts at ~75 and 80 kDa and asterisk marks

772   ~200 kDa species. Representative blot from 4 replicates. (D) Western blot of pooled

773   wild-type larvae probed with pre-immune serum and Actin antibody. (E) zPadi2 western

774   blot of pooled 2 dpf larvae. Lane 1, wild-type; lane 2, *padi2*$^{-/-}$; lane 3, *padi2* 201a mRNA-

775   injected *padi2*$^{-/-}$ larvae. (F) Citrullination activity of Padi2 202 and individual point

776   mutations in select calcium-binding and catalytic amino acids (colors correspond to

777   highlighted residues in B). Fold change of enzymatic activity normalized to wild-type

778   Padi2 202. Data represent 2 independent experiments and wild-type values are also

779   represented in Fig 1 A.

780

781   **Figure S2: Homozygous *padi2* mutants are viable and have increased**

782   **neuromuscular junctions.** (A) Genotype frequency at 5 dpf larvae of incrossed *padi2*

783   heterozygotes. (B) Genotype frequency of adult offspring of incrossed *padi2*

784   heterozygotes. Data in A and B are from four and six clutches, respectively, and

785   analyzed by Chi-squared tests. (C) Representative images of slow-muscle fibers

786   immunostained with α-MyHC antibody in the trunk of 5 dpf larvae from 3 independent

787   replicates. (D) Representative images of the trunk of phalloidin-stained 5 dpf larvae for

788   visualization of F-actin in fast-muscle fibers. Wild-type cousin (left) and *padi2*$^{-/-}$ (right)

789   from 3 independent replicates. (E) Neuromuscular junctions are labeled with α-SV2

790   (green, presynaptic vesicles), α-BTX (red, postsynaptic AChRs), and merge (synapses)

791   in wild-type cousins (top) and *padi2*$^{-/-}$ (bottom) larvae at 5 dpf. (F) Quantification of the

792   number of SV2 puncta, AChR puncta, and synapses in a single myotome in the trunks

793   of larvae. Data are from three pooled independent replicates with the lsmeans ($\pm$) SEM

794   and p values calculated by ANOVA reported. Each symbol represents a single myotome

795   and measurements were taken from two myotomes per larva (n = 100 myotomes from

796   50 wild-type larvae, n = 114 myotomes from 57 *padi2*$^{-/-}$ larvae). Scale bars = 50 μm.

797

798   **Figure S3: Padi2-deficient larvae show regeneration defects.** (A) RT-qPCR of *padi2*

799   exon5/6 on pooled fin extracts from 24 hpw and no wound controls (3dpf) normalized to

800   wildtype, no wound fins. Data are from three pooled independent replicates with the

801   means and SEM reported and a one-sample t test performed. (B) Quantification of

802   regenerative and developmental fin length after morpholino (MO) knockdown of *padi2*.

803   Data from 5 independent replicates with 3 dpw (n = 90 control MO, n = 113 *padi2* MO)

804   and 5 dpf (n = 104 control MO, n = 103 *padi2* MO). (C) Quantification of neutrophils in

805   whole larvae from 3 independent replicates, (n = 30 +/+, 29 -/- at 2 dpf; n = 30 +/+, 30 -/-

806   at 3 dpf). (D) Quantification of neutrophil numbers in developmental, unwounded fins.

807   Pooled from five independent replicates (n = 88 +/+, 78 -/- at 2 dpf and n = 79 +/+, 75 -/-

808   at 3 dpf). (E) Quantification of macrophage numbers in whole larvae from 3 independent

809   replicates (n = 30 +/+, 29 -/- at 2dpf and n = 30 +/+, 30 -/- at 3 dpf). (F) Quantification of

810   macrophage numbers in developmental, unwounded fins. Pooled from 4 independent

811   replicates (n = 81 +/+, 74 -/- at 2dpf and n = 70 +/+, 66 -/-). (G) Representative images

812   of H4cit3 immunostaining in 3 dpf unwounded control larvae with H4cit3 antibody label

813   on the right and merged with the bright-field on the left. (H) Representative multiphoton

814   microscopy 3D reconstruction showing enface view of the notochord bead at 24 hpw in

815   *Tg(lepb:EGFP)* expressing (green) larvae labeled with H4cit3 immunofluorescence

816   (magenta). Last image in row includes brightfield overlay. (I) Section view of the

817   notochord bead, showing enface (x,y view) and orthogonal (x, z view is below; y, z view

818   is to the right) sections, with section thickness shown 2 μm for both x and y, 10 μm in z.

819   Scale bars = 10 μm. (J,L) Representative images of active-Caspase3 labeled in (J)

820   66hpw fins or (L) developmental, unwounded fins. Merged images of active-Caspase3

821   (magenta) and DAPI (white) on the left, and single active-Caspase3 channel in white on

822   the right. (K) Quantification of active-Caspase3 threshold area in *padi2$^{-/-}$* and wild-type

823   fins at 66 hpw from 3 independent replicates (n = 47 +/+, 47 -/-). (M) Representative

824   images at 24 hpw and (N) quantification of mitotic cells labeled with phosphorylated

825   histone H3 in MO injected larvae past the notochord (white dotted line) from 3

826   independent replicates (24 hpw n = 68 control MO, 70 *padi2* MO and 3 dpf n = 71

827   control MO, 64 *padi2* MO). All quantifications have lsmeans and SEM reported and p

828   values were calculated by ANOVA. Scale bars = 100 μm.

829

830

831

832   **Acknowledgements**

844 Author contributions: NG, JMS, MAS, KWE, JK and AH conceived and designed
845 experiments. NG, DAB, JMS, JR, and PP conducted the experiments. NG and DAB
846 performed the analysis. NG, JMS, and AH prepared the figures and wrote the
847 manuscript.
