22 Abstract

23 Mitochondrial genome provides useful information about species with respect to its evolution 24 and phylogenetics. We have taken the advantage of high throughput next-generation 25 sequencing technique to sequence the complete mitogenome of Yellow-billed babbler 26 (Turdoides affinis), a species endemic to Peninsular India and Sri Lanka. Both, reference-27 based and *de-novo* assemblies of mitogenome were performed and observed that *de-novo* 28 assembled mitogenome was most appropriate. The complete mitogenome of yellow-billed 29 babbler (assembled *de-novo*) was 17,671 bp in length with 53.2% AT composition. Thirteen 30 protein-coding genes along with 2 rRNAs and 22 tRNAs were detected along with duplicated 31 control regions. The arrangement pattern of these genes was found conserved among 32 Leiothrichidae family mitogenomes. Downstream bioinformatics analysis revealed the effect 33 of translational efficiency and purifying selection pressure over all the thirteen protein-coding 34 genes in yellow-billed babbler mitogenome. Moreover, genetic distance and variation 35 analysis indicated the dominance of NADH dehydrogenase complex-I in the electron 36 transport system of T. affinis. Evolutionary analysis revealed the conserved nature of all the 37 protein-coding genes across Leiothrichidae family mitogenomes. Our limited phylogenetics 38 results suggest that T. affinis is closer to Garrulax.

39 Key Words: Phylogeny, mitochondrial DNA, birds, tRNA, Control region

40

41 Introduction

42 Aves are one of the most diverse vertebrate classes with a huge number of species having a 43 broad range of ecological behavior and complex morphology, all of which make it difficult to 44 solve the riddles regarding their taxonomy along with phylogenetic and evolutionary 45 relationship¹⁻³. New and advanced scientific techniques have emerged to solve these riddles. 46 For the last few years, genome sequencing has become more popular to obtain huge 47 information on evolutionary history and revising the clustering pattern of traditional taxonomy⁴. Mitochondrial DNA with some of its inherent properties like small genome size, 48 49 absence of extensive recombination frequency, simple structure of genome, maternal 50 inheritance along with rapid evolutionary rate are now extensively utilized in taxonomic and phylogenetic studies of vertebrates⁵⁻¹⁰. Furthermore, it has been reported that, complete 51 52 mitogenomes retain more information than a single gene regarding the evolutionary history of the taxon and also provide consistent results compared to nuclear genes¹¹. This also 53 reduces the effect of homoplasy and frequent stochastic errors in phylogenetic studies¹¹. 54

Yellow-billed bababler (*Turdoides affinis*) is one of the most common birds in India¹². They 55 56 are distributed in the southern peninsular India including the southern part of Maharashtra, Chattisgarh and Andhra Pradesh¹². The taxonomic classification of this bird is guite dubious. 57 Previously all babbler and allies were considered under Timaliidae family¹³. Recent 58 classification studies have split this family into five discrete families¹³. Three of them, 59 60 Leiothrichidae, Pellorneidae and Timaliidae consisted of traditional babblers while 61 Zosteropidae included mainly Yuhina along with some other minor species and Sylviidae grouped all the Sylvia warblers¹⁴. Among these five distinct families, Leiothrichidae 62 63 represented the largest group consisting of 125 species distributed mainly in the Sino-Himalayan and South-Eastern parts of Asia¹⁴. A study on the Leiothrichidae family suggested 64 65 their origin prior to the Miocene–Pliocene boundary, which is well known for its noteworthy

climatic turmoil in Asia¹³.Hence, it is imperative to conduct in-depth molecular studies on
this family to know some very appealing unknown facts regarding their taxonomical and
phylogenetic relationships.

69 This Leiothrichidae family mainly consisted of Grammatoptila, Garrulax, Trochalopteron, *Turdoides* and *Argya*¹⁴. Polyphyletic nature was observed among members of *Turdoides* due 70 71 to which further taxonomic classification was done and some species were resurrected from this genus¹⁴⁻¹⁶. Yellow-billed babbler which is considered to be under *Turdoides* has been 72 73 recently proposed to be under Argya based on revised taxonomy of Leiothrichidae¹⁴; 74 however, more investigations are required to confirm this. Yellow-billed babbler generally 75 live in flocks of seven to ten members continuously squeaking, chattering and chirping. 76 Helpers are seen generally assisting parents in nest building, chick feeding and maintaining nest sanitation as a cooperative breeding character¹⁷⁻¹⁹. Interestingly, the close relatives of T. 77 78 affinis for instance, Garrulax, Leiothrix, Liocichla, Minla and Trochalopteron have still not 79 been reported to show the cooperative breeding behaviour indicating a divergence of T. *affinis* at least from the behavioural ecology perspective¹⁸. 80

Untill now, the complete mitogenomes of various species (including *Garrulax affinis*²⁰, *G. albogularis*, *G. canorus*, *G. canorus* voucher AHNU, *G. cineraceus*²¹, *G. elliotii*²², *G. formosus*²³, *G. ocellatus*²⁴, *G. perspicillatus*²⁵, *G. poecilorhynchus* voucher B33²⁶, *G. sannio*²⁷, *G. sannio* voucher GSAN20150704V3, *Trochalopter onmilnei*, *Leiothrix argentauris*, *L. lutea*, *Liocichla omeiensis*²⁸and *Minla ignotincta*²⁹) from Leiothrichidae family have been reported. However, complete mitogenome of birds representing the genus *Turdoides* is yet to be revealed.

In this study, we have sequenced and described the complete mitochondrial genome of *T.affinis* obtained using two approaches such as reference-based assembly and *de-novo* assembly³⁰⁻³¹. We employed two different genome assembly approaches to align the same 91 mitogenome to quantify the differences occurring due to the alignment approach and their 92 effect on mitogenomic parameters. In addition, we have performed a detailed comparative 93 analysis on available mitogenomes of the family Leiothrichidae to understand the overall 94 species-specific differences including some potent parameters such as codon usage and 95 evolutionary history.

96 Materials and Methods

97 Sample collection and DNA extraction

98 A fresh road-killed specimen of *T. affinis* was collected from Anaikatty Hills in Coimbatore 99 district of Tamil Nadu, India (Fig. 1), and transported immediately to the lab. Prior 100 permission for roadkill collection was obtained from Tamil Nadu Forest Department 101 (Ref.No.WL5 (A)/2219/2018; Permit No. 14/2018). Muscle tissue was sampled from the 102 specimen and stored in DESS buffer (20% DMSO, 0.25M tetra-sodium EDTA, Sodium 103 Chloride till saturation, pH 7.5) at -20°C for further processes. About 50 milligram of the 104 muscle tissue in DESS buffer was taken and added to 500 µl of lysis buffer (10 mM Tris-pH 105 8.0, 10 mM EDTA-pH 8.0, 100 mM NaCl) and homogenized thoroughly. To the 106 homogenate, 80 µl of 10% SDS and along with 20 µl of Proteinase K (20 mg/ml) was added 107 and incubated overnight at 55°C. The DNA extraction was performed the following day 108 using suitable volumes of Phenol, Chloroform and Isoamyl alcohol. The DNA pellet obtained 109 was suspended in 100 µl of Tris-EDTA buffer (Sigma-Aldrich, USA) and quantified using 110 spectrophotometer (DeNovix, USA) and Qubit 4 Fluorometer (ThermoFisher Scientific, 111 USA). The quality of the DNA extracted was assessed by running it on 1% agarose gel 112 stained with ethidium bromide intercalating dye.

113 Library preparation

114 For library preparation, 700 nanograms of extracted DNA was utilized as starting material in 115 NEBNext Ultra II DNA Library Prep kit for Illumina (New England Biolabs, USA). The 116 DNA was fragmented using focused ultrasonicator (Covaris M220, USA) until the desired 117 length of 270-300 base pairs was obtained. The fragmented DNA size was analyzed by 118 running it in Fragment Analyzer (Agilent, USA) making sure that the size of the majority of 119 DNA fragments is between 270-300 base pairs. Adaptor ligation was then carried out in a 120 thermocycler following the "NEBNext Ultra II DNA Library Prep kit for Illumina" protocol 121 using dual indexed primers present in the kit for creation of pair end libraries. After the 122 ligation reaction was completed, the size selection of Adaptor-ligated DNA was carried out 123 using NEBNext Sample Purification Beads (New England Biolabs, USA) followed by PCR 124 enrichment of Adaptor-ligated DNA following the manufacturer's protocol. After the clean-125 up of the enriched DNA, it was again analysed for the required concentration and mean peak 126 size in a Fragment Analyzer (Agilent, USA). The enriched DNA library fragments were 127 subjected to sequencing in Illumina NextSeq 550 (Illumina, Inc., USA) using Illumina High 128 Output Kit for NextSeq 500/550 (Illumina, Inc., USA). A PhiX control library (Illumina, 129 Inc., USA) was also subjected to sequencing along with the sample DNA library as an 130 internal control. At the end of the sequencing run, high quality paired end reads were 131 obtained, and further bioinformatics analysis was performed.

132 Assembly and annotation of the mitochondrial genome

IlluminaNextSeq 550 produced 88,52,137 raw reads from whole-genome library. Cutadapt tool³²was used to trim the adapter and lowquality reads with a Phred (Q) score of 30 was selected for further analysis. Finally we got 12,97,736 high quality reads after down sampling with Seqtk (<u>https://github.com/lh3/seqtk</u>) which were used for assembly. *De novo* assembly was performed using SPAdes-3.11.1 software with default parameters. MITOS online server (http://mitos.bioinf.uni-leipzig.de/index.py) was used for annotation of the mitogenome. Reference-based assembly was also performed as described in supplementary file 1.

140 **Phylogenetic analysis**

Phylogenetic analysis was performed on the available whole mitogenomes of various species of the Leiothrichidae family. We prepared two complete mitogenome based phylogenetic trees, one with *T. affinis* mitogenome assembled through reference-based assembly and another with *de-novo* assembly using Maximum likelihood algorithm with 1000 bootstrap values in ClustalW implemented with Mega ver. 7.

146 Sequence analysis of mitogenome

147 The complete mitogenome of *T. affinis* was compared with other Leiothrichidae family avian 148 species whose complete mitochondrial genomes are available at NCBI including *Garrulax* 149 affinis²⁰, G. albogularis, G. canorus, G. canorus voucher AHNU, G. cineraceus²¹, G. elliotii²², G. formosus²³, G. ocellatus²⁴, G. perspicillatus²⁵, G. poecilorhynchus voucher 150 151 B33²⁶, G. sannio²⁷, G. sannio voucher GSAN20150704V3, Trochalopteron milnei, Leiothrix argentauris, L. lutea, Liocichla omeiensis²⁸ and Minla ignotincta²⁹. These sequences were 152 153 downloaded from NCBI website and used for further comparative analysis. The protein-154 coding genes along with tRNAs and rRNAs were aligned to examine whether any 155 rearrangements persist among these mitogenomes. The initial and terminating codons of all 156 through NCBI ORF the protein-coding genes were curated finder 157 (https://www.ncbi.nlm.nih.gov/orffinder/). Circular genome views were obtained by CG view server³³. determined³⁴. 158 The boundary region (CR)of the control was 159 Detailed codon usage analysis of the select mitogenomes was performed using 160 CodonWsoftware³⁵. The studied codon usage parameters include Relative Synonymous 161 codon Usage (RSCU), Effective number of Codons (ENc) and frequency of G+C at the third 162 position of codons (GC3s). Different codon composition indices of individual genes, for 163 example total GC content as well as the frequency of each nucleotide at the third position of 164 codons (A3, T3, G3 and C3) were also estimated. R-based heatmaps were generated based on

165 the overall codon usage and amino acid usage analysis. Skew values for AT[(A-T)/(A+T)]calculated³⁶using 166 GC and [(G-C)/(G+C)]were DAMBE software 167 (http://dambe.bio.uottawa.ca/DAMBE/dambe.aspx). Tandem Repeats Finder software 168 (https://tandem.bu.edu/trf/trf.html) with its default settings was employed to detect any 169 tandem repeats within the mitogenomes. A BlastN based approach to find intra-genomic duplication of large fragments or interspersed repeats was employed³⁷, where each 170 171 mitogenome was searched against itself with an e-value of 1e-10. This analysis detected a 172 negligible number of interspersed repeats, hence was not evaluated further.

173 Estimation of translational efficiency

174 This parameter measures the competence of codon-anticodon interactions indicating the 175 accuracy of the translational machinery of genes in the absence of preferred codon set 176 information. We calculated the translational efficiency according to the following equation³⁸:

$$P2 = \frac{WWC + SSU}{WWY + SSY}$$

- 177 where, W= A or U, S=C or G and Y=C or U.
- 178 P2 > 0.5 indicates the existence of translational selection.

179 RSCU based cluster analysis and putative optimal codons

Generally, highly expressed genes utilize a specific set of codons termed as optimal codons. Due to the preferential use of this set of codons their Enc value lowers down in contrast to lowly expressed genes, which restrain more rare codons with higher Encvalue³⁵. We identified the optimal codons of all investigated species from their RSCU values. RSCU =1 indicated unbiased codon usage whereas; RSCU > 1 and RSCU < 1 indicated a higher and lower usage frequency of that particular codon respectively³⁵.

186 Evolutionary analysis

187 The ratio (2) of non-synonymous substitution rate per synonymous site (ka) to synonymous 188 substitution rate per non-synonymous site (ks) has been reported to be an excellent estimator 189 of evolutionary selection pressure or constrain on protein-coding genes. $\mathbb{Z}>1$ stands for 190 positive Darwinian selection (diversifying pressure), on the contrary, 2<1 signifies purifying 191 or refining selection. At neutral evolutionary state, the value of Decomes 1 symbolizing the equal rate of both synonymous and non-synonymous substitution³⁹. The mean genetic 192 193 distance of the annotated protein-coding genes of the studied mitogenomes were calculated in 194 terms of Kimura-2-parameter (K2P) substitution model and evolutionary rate (2) was calculated by DnaSPver 6.12.03 software⁴⁰. 195

196 **Results and Discussion**

197 Comparison of *T. affinis* mitogenome assembled using reference-based and *de-novo* 198 assembly approach

199 In this study, we performed both, reference-based assembly and *de-novo* assembly of the 200 newly sequenced mitogenome of T. affinis and found a considerable difference in the results 201 between these two approaches. In reference-based assembly, the total size of the mitogenome 202 was 16,861 bp with 47% GC and 53% AT (Supplementary file 1) whereas the de-203 novo assembly resulted in 17,671 bp long mitogenome with 53.2% AT and 46.80% GC(Fig. 204 2, Table 1). AT and GC skewness were 0.13 and -0.38, respectively for *de-novo* assembly. 205 However, reference-based assembly resulted in lower AT (0.05) and GC skew (-0.14) for T. 206 affinis mitogenome. The Genbank accession number of complete T. affinis mitogenome 207 (assembled *de-novo*) is MN848144.

Two rRNA (rrnS for small subunit and rrnL for large subunit), 13 protein-coding genes (PCGs) and 22 tRNAs specified for 20 amino acids (two tRNAs each for serine and lysine) were reported in both the mitogenomes. The total length of PCGs, tRNAs and rRNAs were 11244 bp, 1539 bp and 2389 bp, respectively for *de-novo* assembly while these were 11247 bp, 1535 bp and 2578 bp respectively for reference-based assembly.

213 The following results were identical for both the mitogenomes. For instance, most of tRNAs

214 (16) were distributed on the positive (+) strand except trnQ(CAA), trnA(GCA), trnN(AAC),

trnC(TGC), trnY(TAC) and trnS2(TCA) that were distributed on the negative (-) strand. Both

rRNAs along with all the PCGs, except nad6, were present on the negative (-) strand.

217 Two non-coding control regions were found and referred to as CR1 and CR2. The 5' 218 boundary of CR1 was trnT(ACA) and 3' boundary was trnP(CCA) while CR2 was present 219 between trnE(GAA) and trnF(TTC). Length of CR1 and CR2 were 1138 bp and 1159 220 bp, respectively in *de-novo* assembly (at parwith the other compared species) while for 221 reference-based assembly CR1 was 825bp (less than the average CR1 length of other 222 compared species by 300bp) and CR2 was 1539bp long (extra 390bp than the average CR2 223 length of compared species). The nucleotide composition of both CR1 and CR2 was 224 calculated. AT of CR1 was 54.63% (45.37% GC) for *de-novo* assembly and 53.68% (46.32% 225 GC) for reference-based assembly. CR2 showed 53.78% AT (46.22% GC) and 55.9% AT 226 (44.1% GC) for *de-novo* and reference-based assembly, respectively indicating a bias towards 227 an AT for these regions. rRNAs, tRNAs and PCGs were arranged in the following manner in 228 both the assemblies:

229 trnF-rrnS-trnV-rrnL-trnL2-nad1-trnI-trnQ-trnM-nad2-trnW-trnA-trnN-trnC-trnY-cox1-trnS2-

230 trnD-cox2-trnK-atp8-atp6-cox3-trnG-nad3-trnR-nad4l-nad4-trnH-trnS1-trnL1-nad5-cob-

trnT-trnP-nad6-trnE.

232 These results showed considerable differences between reference-based assembly and de-233 novo assembly. Further, we performed a limited phylogenetic analysis with both the 234 mitogenomes, and observed that *de-novo* assembled mitogenome performed better. The 235 phylogenetic analysis of reference-based assembled mitogenome placed 236 T. affinis with Leiothrix lutea (Supplementary file 2), whereas in case of de-novo assembled 237 mitogenome based phylogeny, T. affinis formed a discrete group which was placed near *Garrulax affinis*(Fig. 3). The later finding is consistent with a recent report¹⁴ that revised 238

the taxonomy of Leiothrichidae using a set of nuclear genes with a mitochondrial PCG as a phylogenetic marker. Though our phylogenetic results are limited because of the unavailability of complete mitogenome sequences of other groups, still it provides supporting evidences that *de novo* assembled mitogenome is more appropriate.

243 Nucleotide composition and translational efficiency

244 The newly sequenced complete mitogenome of *T. affinis* was compared with other available 245 mitogenomes from the Leiothrichidae family (Table 2). We considered Garrulax 246 affinis(KT182082.1)²⁰, G. albogularis(KX082660.1), G. canorus(KT633399.1), G. canorus 247 voucher AHNU (JQ348398.1), G. cineraceus(KF926988.1)²¹, G. elliotii(KT272404.1)²², G. formosus(KR020504.1)²³, G. ocellatus(KP995195.1)²⁴, G. perspicillatus(KF997865.1)²⁵, G. 248 poecilorhvnchus voucher B33 (KR909134.1)²⁶, G. sannio(KR869824.1)²⁷, G. sannio voucher 249 250 GSAN20150704V3 (KT373847.1), Leiothrix argentauris(HQ690245.1), L. lutea(JQ423933.1), Liocichla omeiensis(KU886092.1)²⁸, Minla ignotincta(KT995474.1)²⁹ 251 252 and Trochalopteron milnei(MH238447.1). Gene arrangement pattern was observed among 253 these species and was found similar to that of T. affinis (Fig. 4). Values of AT skew ranged 254 from 0.09 (T. milnei) to 0.13 (Turdoides affinis) while the GC skew ranged from -0.39 (G. 255 albogularis) to -0.36 (L. omeiensis) (Table 2). Comparative RSCU analysis identified a set of 256 optimal codons common among all species - GCC(A), UGC(C), UUC(F), GGA(G), AAA(K), 257 CUA(L), UUA(L), AUA(M), CCU(P), CAA(Q), AGC(S), ACC (T) and GUA(V). Along 258 with these GCU(A), GCA(A), GAC(D), GAA(E), CAC(H), AUU(I), CUC(L), CUU(L), 259 AAU(N), CCC(P), CGC(R), UCU(S), ACU(T), GUC(V), UGA(W) and UAC(Y) were also 260 frequently used in T. affinis. Heatmaps based on codon and amino acid usage (Fig. 5) 261 analysis of compared mitochondrial genomes validated the aforementioned codon preference.

GC3 vs. Enc plot analysis has been proved very efficient in predicting whether translational
 selection or mutational pressure persist over the genes of interest³⁵. The GC3-Enc

264 plots(Fig.6a) of protein-coding genes of the compared mitogenomes were placed well below 265 the curve indicating the predominance of selection pressure over mutational bias. RSCU 266 analysis revealed a higher degree of concord among Leiothrichidae mitogenomes from the 267 codon usage perspective (Fig. 6b, Supplementary file 3). To substantiate the factors 268 governing this codon practice GC3 vs. Enc plot analysis was done. It has been proposed that, 269 GC3-Enc plot of genes should be placed on or above the continuous Enc curve when only 270 mutational pressure prevails. However, in the presence of translational selection, the plots 271 should fall well below the aforementioned curve³⁵. Here the GC3-Enc plots of protein-coding 272 genes of all studied mitogenomes were below the curve designating the influence of 273 translational selection over those genes. Hence, we conclude that, the codon usage pattern of 274 T. affinis mitogenome along with other examined species is affected by the pervasiveness of 275 translational selection over mutational pressure.

276 Moreover, values of WWC, SSU, WWU and SSC calculated from the RSCU tables for 277 detecting the translational efficiency clearly indicated the preference of WWC and SSC over 278 WWU and SSU. This pointed towards the selection of C between the pyrimidines (C or U) at 279 the third position of codons. Calculated P2 values were greater than 0.5 for all the protein-280 coding genes in the investigated Leiothrichidae mitogenomes (Table 1, Supplementary file 3) 281 signifying the pivotal role of translational efficiency in dictating the codon usage pattern. 282 Translational selection along with translational efficiency plays a pivotal role in natural selection escorting towards codon preference³⁵. Inclination towards translational efficiency 283 284 also leads to favor codons matching with the restricted anticodon repertoire of mitochondrial 285 tRNAs⁴¹enhancing their competence in the last phase of the central dogma. The nucleotide at 286 the third degenerating position of the codon is responsible for the superlative codon-287 anticodon binding energy³⁸. Previous studies have found that, U is preferred at the third 288 position specifically when G or C is present in the first two positions. On the contrary, when 289 the first two positions are taken by A or U; C is the 'right choice' (at third position)³⁸. Thus, 290 translational efficiency can be characterized by the P2 index, which allows us to choose 291 between the pyrimidines in codons with UU, UA, AA, AU, GG, GC, CG and CC in the first 292 and second position. Results from this analysis clearly (p2>0.5) validated the accountability 293 of translational efficiency suggesting that those genes may have gone through several 294 adaptations with rapid changes in their expression level. The cumulative effect of all these 295 has enhanced the capability of mitochondrial metabolic processes substantiating boisterous 296 nature of these birds. This result showed similarity with a previous study on Dragonflies 297 where the increased mitochondrial capacity aided their elevated flight ability⁴².

298 Comparative mitochondrial genomics

299 The select mitogenomes were compared with T. affinis mitogenome (do novo assembled) for 300 tRNA anticodons, start and stop codons, strand variability, intergenic and overlapping 301 regions, GC/AT skew and RSCU (Supplementary file 3). The comparative anticodon analysis 302 revealed an identical pattern of anticodon usages for all tRNAs among the investigated 303 mitogenomes. Most of the protein-coding genes start with ATG in all the mitogenomes. 304 AGG, AGA, TAG and TAA were identified as stop codons for most of the PCGs; however, 305 in every mitogenome, there were some stop codons, which could not be perfectly identified 306 (Supplementary file 3). Strand variation property showed an exact pattern among the studied 307 mitogenomes Both rRNAs were on positive (+) strand. Except for nad6, all other PCGs were 308 also on the positive (+) strand. While tRNA Q, tRNA N, tRNA C, tRNA Y, tRNA A, tRNA 309 S2, tRNA P and tRNA E were located on the negative (-) strand, the other tRNAs were on 310 positive (+) strand. RSCU based analysis revealed GCC(A), UGC(C), UUC(F), GGA(G), 311 AAA(K), CUA(L), UUA(L), AUA(M), CCU(P), CAA (Q), AGC(S), UCC(S), ACC(T) and 312 GUA(V) as optimal codons in the investigated mitogenomes. The comparative analysis of 313 intergenic and overlapping regions also revealed identical pattern among studied 314 mitogenomes. Intergenic regions were found between trnL2(taa) and nad1, nad1 and 315 trnI(gat), trnI(gat) and trnQ(ttg), nad2 and trnW(tca), trnA(tgc) and trnN(gtt), trnS2(tga) and 316 trnD(gtc), trnD(gtc) and cox2, atp6 and cox3, nad3 and trnR(tcg), nad4 and trnH(gtg), 317 trnL1(tag) and nad5, nad5 and cob, cob and trnT(tgt), trnT(tgt) and trnP(tgg) (CR1) along 318 with trnP(tgg) and nad6 (Supplementary file 3). The intergenic region between trnT(tgt) and 319 trnP(tgg) were longest ranging from 939 bp (G. cineraceus) to 1139bp (G. albogularis). 320 Overlapping regions were much shorter, ranging from 2 to 5 bp (Supplementary file 3). The 321 highest overlapping length was between nad4l and nad4 (4bp for G. poecilorhynchus voucher 322 B33 and *T. affinis*, and 5 bp for other mitogenomes(Supplementary file 3). These characters 323 revealed identical patterns for the aforementioned characteristics in the compared 324 mitogenomes.

325 Comparative tRNA structure analysis of *T. affinis de-novo* mitogenome

326 The wobble base pairing which does not follow the Watson-Crick base pairing rule is of 327 immense importance in studying the tRNA structure often substituting GC or AT base pairs contributing to thermodynamic stability⁴³. All these features together affect several biological 328 329 processes⁴⁴. Studies have reported that, RNA binding proteins generally adhere to G-U sites differing from the Watson-Crick or other mis-matched base-pair pattern⁴⁵. Hence, while 330 understanding the exact functional features of mitogenomes, tRNA acts as a pivotal tool ^{45,46}. 331 332 In T. affinis, all the tRNAs were folded into classic secondary clover-leaf structure. In T. 333 affinismitogenome, though Watson-Crick base pair dominated, wobble base pairs were also 334 detected (Fig. 7). For instance, trnA, trnC, trn E, trnN, trnP, trnS1, trnS2 and trnY had wobble 335 base pairing at the acceptor arm. Moreover, trnA, trnC, trnS1, trnQ, trnP and trnN contained 336 wobble base pairing at TYC stem. Same G-U base pairs were also detected at the anticodon 337 stem of trnC, trnP, trnQ, trnS1 and trnT. Three consecutive wobble base pairs were detected 338 at DHU loop of trnS2. Along with, some other mismatched base pairs were also found in 339 trnD, trnE, trnG, trnH, trnM and trnL2. Among other species considered in the present study, all the tRNAs were found to be folded in clover-leaf structure with dominating Watson-Crick

341 base pairing.

342 Control region of *T. affinis de-novo* mitogenome

343 Vertebrate mitochondrial Control Region (CR) is divided in to three domains (I, II and III)⁴⁶. 344 Domain I contains three Extended Terminal Associated Sites (ETAS) proceeded by a C-rich region. Domain II contains F-box, E-box, D-box, C-box and B-box⁴⁷. For birds, there is a 345 346 special Bird Similarity Box (BSB) present in the left side of B-box in domain II. Domain III 347 consists of three conserved sequence blocks (CSB-I, II, III). Domain III also contains 348 replication origin of H-strand along with bi-directional promoters for both H- and L-strand 349 transcription. Domain II is supposed to be more conserved than Domain I and III⁴⁷. Among 350 all the investigated species of Leiothrichidae family, a duplication of CR was observed. All 351 the aforementioned domains and conserved boxes were identified through sequence 352 alignment. Conserved BSB was prominent in both CR1 and CR2 (Fig. 8). No tandem repeats 353 were found among the CRs. Duplication of CR region is important in regulation of 354 replication and transcription within mitochondrial genome⁴⁶. Moreover, duplicated CR is also associated with extended longevity of bird species⁴⁸. Thus, the present study reported the 355 356 genetic features of duplicated CR among select Leiothrichidae members including T. affinis, 357 which will further be helpful in evolutionary analysis of this group.

358 Evolutionary analysis

Genetic and evolutionary distance calculation revealed higher K2P distance in nad2, atp8 and nad6 whereas cox1 possessed the lowest value among the Leiothrichidae family (Fig. 9). Regarding the ka/ks analysis, the average synonymous substitution rate (Ks) for nd2 gene was highest whereas non-synonymous substitution rate (ka) was highest for atp8. [2](ka/ks) values of the protein-coding genes ranged from 0.014 to 0.183 and was in the following order- cox1<cox3<nad1<cob<nad41<atp6<nad4<cox2<nad3<nad5<nad6<nad2<atp8

365 (Supplementary file 3). Lowest K2P distance for cox1 gene indicated towards its conserved 366 nature among the Leiothrichidae family. Moreover, this also implicated the preference of 367 NADH:ubiquinoneoxidoreductase (complex I) over the succinate dehydrogenase complex in 368 electron transport chain all through the examined family. Complex I is responsible for 369 exporting four H+ ion out of the mitochondrial matrix participating in the generation of H+ 370 gradient across the mitochondrial membrane, which ultimately speeds up ATP generation 371 whereas this mechanism is totally absent when complex II is used⁴⁹. Moreover, the non-372 synonymous substitution rate of cox1 was also found to be least, indicating its conserved 373 nature in mitochondrial machinery of Leiothrichidae family. Mitochondria associated NADH 374 dehydrogenase 2 encoded by the nad2 gene is also a subunit of complex 1 located in the inner mitochondrial membrane and is the largest complex of ETS⁴⁹. The high synonymous 375 376 substitution rate (Ks) of nad2 gene further indicated the preserved amino acid component of 377 complex I. Highest Ka value of atp8 pointed to a highly variable nature of this protein indicating the erratic nature of mitochondrial atp8 among vertebrates⁵⁰. The \square (ka/ks) values 378 379 of all the protein-coding genes were <1 suggesting the persistence of purifying selection 380 against deleterious mutation. Thus, the evolutionary analysis aided in understanding the 381 influence of natural selection manipulating species evolution along with the interaction 382 between selection and mutational pressure responsible for protein evolution which has been 383 already suggested³⁹.

384 Conclusion

We report for the first time the complete mitogenome of *Turdoides affinis*(MN848144).We find the *de-novo* assembly approach more appropriate than a reference-based assembly approach. The comparative mitogenomics of the Leiothrichidae family reveals their preference towards AT-rich codons as well as the persistence of translational efficiency. tRNA analysis shows the dominance of Watson-Crick base pairing with a few exceptions of

wobble base pairing. Duplicated control regions are found among Leiothrichidae family mitogenomes that may help in their extended longevity. Evolutionary analysis confirms thatprotein-coding genes are under purifying selection pressure. Genetic distance and variation analysis indicate the dominance of NADH dehydrogenase complex-I in the electron transport system of *T. affinis*.Our limited phylogenetics results suggest that *T. Affinis* is closer to *Garrulax*.
