Abstract

10 The anaerobic gut fungi (AGF, Neocallimastigomycota) reside in the alimentary tracts of 11 herbivores where they play a central role in the breakdown of ingested plant material. Accurate 12 assessment of AGF diversity has been hampered by inherent deficiencies of the internal 13 transcribed spacer1 (ITS1) region as a phylogenetic marker. Here, we report on the development 14 and implementation of the D1/D2 region of the large ribosomal subunit (D1/D2 LSU) as a novel 15 marker for assessing AGF diversity in culture-independent surveys. Sequencing a 1.4-1.5 Kbp 16 amplicon encompassing the ITS1-5.8S rRNA-ITS2-D1/D2 LSU region in the ribosomal RNA 17 locus from fungal strains and environmental samples generated a reference D1/D2 LSU database 18 for all cultured AGF genera, as well as the majority of candidate genera encountered in prior 19 ITS1-based diversity surveys. Subsequently, a D1/D2 LSU-based diversity survey using long 20 read PacBio SMRT sequencing technology was conducted on fecal samples from 21 wild and 21 domesticated herbivores. Twenty-eight genera and candidate genera were identified in the 17.7 K 22 sequences obtained, including multiple novel lineages that were predominantly, but not 23 exclusively, identified in wild herbivores. Association between certain AGF genera and animal 24 lifestyles, or animal host family was observed. Finally, to address the current paucity of AGF 25 isolates, concurrent isolation efforts utilizing multiple approaches to maximize recovery yielded 26 216 isolates belonging to twelve different genera, several of which have no prior cultured-27 representatives. Our results establish the utility of D1/D2 LSU and PacBio sequencing for AGF 28 diversity surveys, and the culturability of a wide range of AGF taxa, and demonstrate that wild 29 herbivores represent a vet-untapped reservoir of AGF diversity.

Introduction

Members of the anaerobic gut fungi (AGF) are strict anaerobes that inhabit the rumen and alimentary tract of a wide range of foregut and hindgut herbivores. The AGF play an important role in the breakdown of ingested plant biomass via enzymatic and physical disruption in the herbivorous gut ¹. AGF represent a distinct basal fungal phylum (Neocallimastigomycota) that evolved 66 (\pm 10) million years ago coinciding, and possibly enabling, mammalian transition from insectivory to herbivory ².

37 Culture independent amplicon-based diversity surveys have been widely utilized to gauge anaerobic fungal diversity and community structure in herbivores ^{3,4,5,6}. The internal transcribed 38 39 spacer1 (ITS1) region within the ribosomal operon has been almost exclusively utilized as the 40 phylogenetic marker of choice in culture-independent sequence-based phylogenetic assessments 41 of AGF diversity ⁷. Such choice is a reflection of its wider popularity as a marker within the kingdom Mycota^{8,9}, the high sequence similarity and limited discriminatory power of the 18S 42 43 rRNA gene between various AGF taxa¹⁰, and its relatively shorter length, allowing high 44 throughput pyrosequencing- and Illumina-based diversity assessments ^{3,6}. However, concerns for the use of ITS1 in diversity assessment for the Mycota¹¹, basal fungi¹², and the 45 46 Neocallimastigomycota⁷ have been voiced. The ITS1 region is polymorphic, exhibiting 47 considerable secondary structure (number and organization of helices ¹³), and length ¹⁴ 48 variability. Such polymorphism renders automated alignments, reproducible sequence 49 divergence estimates, and classification of sequence data unreliable and highly dependent on 50 alignment strategies and parameters specified. In addition, significant sequence divergence between copies of the ITS1 region within a single strain have been reported (up to 12.9% in ¹⁵), 51 52 values that exceed cutoffs utilized for species (even genus in some instances) level delineation

from sequence data ^{3, 16, 17, 18}. Such limitations often necessitate laborious subjective manual 53 54 curation and secondary structure incorporation into alignment strategies ¹³, although it is well 55 recognized that these efforts only partially alleviate, rather than completely address, such 56 fundamental limitations. 57 The 28S large ribosomal subunit (LSU) is one of the original genes proposed for fungal barcoding ¹². Hypervariable domains 1 and 2¹⁹ within the LSU molecule (D1/D2 LSU) have 58 59 previously been utilized for differentiating strains of AGF via molecular typing ^{20, 21, 22}, or sequencing ^{23, 24}. Compared to ITS1, D1/D2 LSU region exhibits much lower levels of length 60 heterogeneity and intra-strain sequence divergence in fungi²⁵, including the AGF²⁰. 61 62 Identification and taxonomic assignment of AGF strains based on D1/D2 LSU have gathered 63 momentum; and D1/D2 LSU-based phylogenetic analysis has been reported in all manuscripts describing novel taxa since 2015^{15, 26, 27, 28, 29, 30, 50}. The potential use of D1/D2 LSU as a marker 64 65 in culture-independent AGF diversity surveys has been proposed as a logical alternative for ITS1 66 7,14 . The lack of specific AGF primers and the relatively large size of the region (approximately 67 750 bp) has been viewed as a barrier to the wide utilization of short read, high-throughput, 68 Illumina-based amplicon sequencing in such surveys. However, the recent development of AGF LSU-specific primers ^{24, 31}, as well as the standardization and adoption of PacBio long-read 69 70 sequencing for amplicon-based diversity surveys ^{32, 33} could enable this process. 71 Theoretically, a comprehensive assessment of diversity and community structure of a 72 host-associated lineage necessitates sampling all (or the majority) of hosts reported to harbor 73 such lineage. However, to date, the majority of AGF diversity surveys conducted have targeted a few domesticated herbivores, e.g. cows, sheep, and goats ^{4, 5, 34}. "Exotic" animals have been 74 75 sampled from zoo settings only sporadically, and on an opportunistic basis ^{3, 35}.

76 Isolation of AGF taxa enables taxonomic, metabolic, physiological, and ultrastructural 77 characterization of individual taxa. As well, cultures availability enables subsequent –omics, synthetic and system-biology, and biogeography-based investigations ^{36, 37, 38, 39, 40, 41, 42}, as well 78 79 as evaluation of evolutionary processes underpinning speciation in the AGF^{2,43}. However, 80 efforts to isolate and maintain AGF strains have lagged behind their aerobic counterparts mainly 81 due to their strict anaerobic nature and the lack of reliable long-term storage procedures. Due to 82 these difficulties, many historic isolates are no longer available, and most culture-based studies 83 report on the isolation of a single or few strains using a single substrate/enrichment condition from one or few hosts ^{29,44}. Indeed, a gap currently exists between the rate of discovery (via 84 85 amplicon-based diversity surveys) and the rate of isolation of new taxa of AGF, and several yet-86 uncultured AGF lineages have been identified in culture-independent diversity surveys ¹⁷. 87 Whether yet-uncultured AGF taxa are refractory to isolation, or simply not yet cultured due to 88 inadequate sampling and isolation efforts remains to be seen. 89 The current study aims to expand our understanding of the diversity of AGF while 90 addressing all three impediments described above. First, we sought to develop D1/D2 LSU as a 91 more robust marker for AGF diversity assessment by building a reference sequence database 92 correlating ITS1 and D1/D2 LSU sequence data from cultured strains and environmental 93 samples. Second, we sought to expand on AGF diversity by examining a wide range of animal 94 hosts, including multiple previously unsampled wild herbivores. Third, we sought to demonstrate 95 the utility of intensive sampling and utilization of various isolation strategies in recovering AGF 96 strains and testing the hypothesis that many yet-uncultured AGF lineages are indeed amenable to 97 cultivation. Collectively, these efforts provide an established framework for future utilization of

- 98 D1/D2 LSU amplification and PacBio sequencing for AGF community assessment, highlight the
- 99 value of sampling wild herbivores, and establish the culturability of a wide range of AGF taxa.

Results

101	A reference D1/D2-LSU dataset for the Neocallimastigomycota. A 1.4-1.5 Kbp amplicon
102	product encompassing the ITS1-5.8S-ITS2-D1/D2 LSU region was amplified and sequenced
103	from AGF pure cultures and environmental samples to correlate the D1/D2 LSU region to the
104	corresponding ITS1 region, and to provide a reference D1/D2 database for future utilization in
105	high-throughput diversity surveys. Using this approach, representative D1/D2 LSU of all the
106	previously cultured AGF genera Agriosomyces, Aklioshbomyces, Anaeromyces,
107	Buwchfawromyces, Caecomyces, Capellomyces, Cyllamyces, Ghazallomyces, Joblinomyces,
108	Feramyces, Khyollomyces, Liebetanzomyces, Neocallimastix, Orpinomyces, Pecoramyces,
109	Piromyces, and Tahromyces were obtained (Table 1). Representatives of the genus Oontomyces
110	were not encountered in this study, but reference LSU and ITS1 sequences were obtained from
111	prior publication ²⁶ . In addition, representative sequences of D1/D2 LSU of candidate genera
112	AL3, AL4, AL8, MN3, MN4, SK3, and SK4, previously identified in ITS1 culture-independent
113	datasets were also obtained (Table 1, Datasets 1-3). Finally, representatives of six completely
114	novel AGF candidate genera (RH1-RH6) were also identified (Table 1, Datasets 1-3) and
115	confirmed as novel independent clades in ITS1 and D1/D2 LSU-based phylogenetic analysis. It
116	should be noted that multiple previously reported yet-uncultured (candidate) genera have
117	recently been successfully isolated, e.g. AL1 (Khyollomyces), AL5 (Joblinomyces), AL6
118	(Feramyces), AL7 (Piromyces finnis), MN1 (Cyllamyces), SP4 (Liebetanzomyces), and SK2
119	(Buwchfawromyces). In addition, some previously proposed candidate genera clustered as
120	members of already existing genera in our analysis, e.g. SP8 with Cyllamyces, and SP6 with
121	Neocallimastix (Table 1). As such, we estimate that only representatives of candidate genera
122	BlackRhino, SP1, SP2 ¹⁷ , and the relatively rare AL2, DA1, DT1, JH1/SP5 (ITS1 sequence

123	representatives of these two candidate genera are 99.6% similar and so they should be considered
124	as one candidate genus), KF1, MN2, SK1, SP3, and SP7 ^{3, 5, 13, 17, 45, 46, 47, 48} were not encountered
125	in this study, and hence no reference LSU sequence data for these candidate genera are currently
126	available (Table 1).

- 127 D1/D2 LSU versus ITS1 as a taxonomic marker.
- 128 Intra-genus length variability.
- 129 The ITS1 and D1/D2 LSU regions were bioinformatically extracted from the 116 Sanger-
- 130 generated clone sequences from this study and previous studies ^{23, 28, 29, 49} (accession numbers in
- 131 Table 1), the rRNA loci from two Neocallimastigomycota genomes (Pecoramyces ruminantium
- 132 strain C1A, and *Neocallimastix californiae* strain G1)^{36,43} in which the entire rrn operon
- 133 sequence data is available, and from the PacBio-generated environmental amplicons in this
- 134 study. The ITS1 region displayed a high level of length heterogeneity, ranging in size between
- 135 141 and 250 bp (median 191 bp, Figure 1a), with 75% of sequences ranging between 182-208 bp
- in length. Some genera had shorter than median ITS1 region length, e.g. Cyllamyces (range 141-
- 137 173 bp), *Buwchfawromyces* (range 155-169 bp), and candidate genus AL3 (range 145-148 bp),
- 138 while others exhibited a longer than median ITS1 region length, e.g. *Liebetanzomyces* (range
- 139 198-225 bp), and candidate genus RH5 (range 191-224 bp) (Figure 1a). A third group of genera
- 140 displayed a wide range of length heterogeneity, e.g. *Neocallimastix* (range 160-244 bp),
- 141 *Caecomyces* (range 192-250), and *Piromyces* (range 173-225 bp). Few genera and candidate
- 142 genera displayed a fairly narrow range of ITS1 length, e.g. AL3 (141-148 bp), but this is
- 143 potentially a reflection of the paucity of sequences belonging to these genera obtained in this
- 144 study (Figure 1a).

145 On the other hand, a much lower level of length heterogeneity was identified in the

146 D1/D2 LSU (Figure 1b), ranging in size between 740-767 bp (median 760 bp), and where 75%

- 147 of the sequences ranged between 757-761 bp, with all genera consistently displaying a much
- 148 narrower D1/D2-LSU length heterogeneity, ranging between 11 bp in RH4 and 26 bp in the
- 149 genera Neocallimastix and Aklioshbomyces.

150 Intra-genus sequence divergence.

- 151 The ITS1 region displayed intra-genus sequence divergence ranging from 0.4 to 21% (median
- 152 3.2%), with 75% of the pairwise divergence values ranging between 1.7-6%. Genera displaying
- the highest level of divergence were *Caecomyces* (1-18.9%, median 8.3%), *Cyllamyces* (0.6-
- 154 19.6%, median 5.5%), and *Neocallimastix* (0.4-19.3%, median 5.5%) (Figure 1c). On the other
- hand, intra-genus sequence divergence of the D1/D2 LSU ranged between 0.1-9.2% (median
- 156 1.4%), with 75% of the pairwise divergence values ranging between 0.8-2.1%. Genera
- displaying highest level of divergence were *Feramyces* (0.1-7.8%), *Joblinomyces* (0.1-8.7%,
- 158 *Caecomyces* (0.1-9%), and *Piromyces* (0.1-9.2%) (Figure 1d).

159 Within strain length variability.

- 160 Within strain length heterogenicity examined in 19 strains with 2 or more sequenced clones
- 161 ranged between 0-5 bp (Figure 2a) for ITS1 region and 0-1 bp for the LSU region (Figure 2b).

162 Within strain sequence divergence.

- 163 Examining the 19 strains with more than two sequenced clones, the full ITS1 region showed
- 164 intra-strain sequence divergence ranging from 0.1-10.01% (Figure 2c). Similar, and even higher
- levels of intra-strain ITS1 variability was previously reported e.g. up to 12.9% in
- 166 Buwchfawromyces eastonii strain GE09¹⁵. On the other hand, within strain D1/D2 LSU rRNA
- region showed a much lower sequence divergence, ranging from 0.13-1.84% (Figure 2d).

168 Neocallimastigomycota diversity assessment using D1/D2 LSU as a phylogenetic marker.

169 *Phylogenetic diversity and Novelty.*

170 A total of 17,697 high-quality long-read amplicons were obtained. Phylogenetic analysis using

- 171 the D1/D2 LSU amplicons assigned all sequences into 28 different genera/candidate genera
- 172 (Figure 3a, Figure 4a, Figure S1) and 298 species level OTUs_{0.02}. AGF genera identified in this
- 173 study included members of the previously described genera Anaeromyces, Buwchfawromyces,
- 174 Caecomyces, Cyllamyces, Liebetanzomyces, Neocallimastix, Orpinomyces, Pecoramyces, and
- 175 *Piromyces.* In addition, sequences representing multiple novel genera were also identified
- 176 (Figure 3a, Figure 4a, Figure S1), some of which have been subsequently isolated, named, and
- 177 characterized in separate publications, e.g. *Feramyces* ²⁸, *Aklioshbomyces*, *Agriosomyces*,
- 178 *Ghazallomyces*, and *Khyollomyces* ⁵⁰. Finally, six novel candidate genera were identified and
- designated RH1-RH6 (Figure 3a, Figure 4a, Figure S1). All of these six novel genera were
- 180 encountered in extremely low abundance in a few samples (Figure 3a), with the notable
- 181 exception of RH5, which was present in high relative abundance in multiple animals e.g.
- domesticated sheep (96.22%), blackbuck deer (52.41%), axis deer (20.71%), and an aoudad
- 183 sheep sample (11.75%).

184 *Diversity estimates, and distribution patterns.*

185 The number of AGF genera encountered per sample varied widely from 5 (in Pere David's deer,

- and Longhorn cattle) to 16 (in one Aoudad sheep sample) (Table 2, Figure 3a, Figure 4a).
- 187 However, in each of these samples a distribution pattern was observed in which a few genera
- represent the absolute majority of the sequences obtained. Excluding genera present in less than
- 189 1% abundance would lower the number of genera encountered per animal to 1 (in white-tail deer

and dwarf goat) -10 (domesticated goat). Usually, 1-5 taxa were present in >10% abundance per
animal (Figure 3b).

192	Using empirical cutoffs for ubiquity (presence in at least 50% of the animals studied) and
193	abundance (above 1%), we identify five different distribution patterns for AGF genera
194	encountered in this study (Figure 4b); 1. Ubiquitous mostly abundant genera: These are the
195	genera identified in at least 50% of the animals studied and where their relative abundances
196	exceed 1% in at least 50% of their hosts: This group includes Piromyces, Feramyces,
197	Khyollomyces, RH5, Neocallimastix, Cyllamyces, and Caecomyces. 2. Ubiquitous mostly rare
198	genera: These are the genera identified in at least 50% of the animals studied and where their
199	relative abundances were lower than 1% in at least 50% of their hosts. This group includes
200	Orpinomyces, and Pecoramyces. 3. Less ubiquitous but mostly abundant genera: These are the
201	genera identified in $< 50\%$ of the animals studied but where their relative abundances exceed 1%
202	in at least 50% of their hosts. This group includes Ghazallomyces, RH4, MN4, Joblinomyces,
203	SK4, Buwchfawromyces, AL3, RH1, and RH3. 4. Less ubiquitous mostly rare genera: These are
204	the genera identified in $< 50\%$ of the animals and where their relative abundances were lower
205	than 1% in at least 50% of their hosts. This group includes Liebetanzomyces, Anaeromyces, AL8,
206	Aklioshbomyces, RH2, and Agriosomyces. 5. Less ubiquitous consistently rare genera: These are
207	the genera identified in $< 50\%$ of the animals and where their relative abundances never
208	exceeded 1% in any of their hosts. This group includes RH6, AL4, MN3, and SK3.
209	Multiple diversity estimates (number of observed genera, Chao and Ace richness
210	estimates, Shannon diversity index, Simpson evenness, as well as diversity rankings) were
211	computed for each sample (Table 2). The highest genus-level richness was observed in aoudad
212	sheep, dwarf goat, oryx, domesticated cow, domesticated goat, miniature donkey, zebra, and

blackbuck deer samples, while the highest genus-level diversity (based on diversity ranking and
Shannon index) was observed in domesticated goat, alpaca, axis deer, blackbuck deer, mouflon
ram, miniature donkey, oryx, and domesticated horse. On the other hand, the lowest genus-level
richness was observed in longhorn cattle, Pere David's deer, Boer goat, domesticated horse,
domesticated sheep, and alpaca, while the lowest genus-level diversity was observed in Fallow
deer, zebra, domesticated sheep, dwarf goat, and white-tail deer.

219 When correlated to animal host phylogeny or animal lifestyle (24 possible combinations), 220 all diversity estimates showed low correlation coefficients (Cramer's V statistic < 0.49) at both 221 the genus and the species equivalent levels (Table S1). Student t-tests were used to examine the 222 significance of the difference in diversity estimates at the genus and species equivalent levels 223 between animal host families (families Bovidae, Cervidae, and Equidae) as well as animal 224 lifestyle (zoo-housed, wild, and domesticated). Only three of these showed a significant 225 difference (Student t-test p-value <0.05): Family Bovidae had a significantly higher observed 226 number of genera and significantly higher Chao estimate at the genus level, and zoo-housed 227 animals had significantly lower Shannon diversity at the species equivalent level (Table S1).

228 *Community structure*.

We used a combination of ordination methods and Student t tests to identify associations
between AGF genera and host factors. Non-metric multidimensional scaling based on the genuslevel Bray-Curtis indices (Figure 5a-b) identified a few patterns. The genera *Aklioshbomyces*, *Ghazallomyces, Joblinomyces, Feramyces, Buwchfawromyces*, and *Pecoramyces* seem to be
more prevalent in some wild animals (e.g. black buck deer, mouflon, oryx, axis deer, and white
tailed deer; filled squares in Figure 5a), while some zoo-housed animals (e.g. elk, dwarf goat,
and miniature donkey; grey squares in Figure 5a) clustered together based on the abundance of

236 Neocallimastix, Caecomyces, and Liebetanzomyces. Few domesticated animals (e.g.

237 domesticated goat, longhorn, alpaca, and domesticated cow; open squares in Figure 5a) clustered

together based on the abundance of *Cyllamyces*, AL8, MN3, MN4, RH1, RH3, RH4, and RH6.

Animal host family had a slightly less apparent effect on AGF community structure (Figure 5b)

240 with the exception of the importance of Aklioshbomyces and Ghazallomyces in family Cervidae,

and AL3 and *Khyollomyces* in family Equidae.

242 To test the significance of these observed patterns, Student t-tests were used to identify

significant associations between specific AGF taxa and host phylogeny (families Bovidae,

244 Equidae, Cervidae), or animal lifestyle (zoo-housed, domesticated, wild). From all possible

associations (168 total; 28 genera x 3 host families and 3 lifestyles), significant differences were

observed only in the following cases. The AGF genera AL3, *Khyollomyces*, and *Piromyces* were

significantly more abundant in family Equidae (p-value=0.014, 0.018, and 0.034 respectively),

248 while the genera *Aklioshbomyces*, *Ghazallomyces*, and *Joblinomyces* were significantly more

abundant in family Cervidae (p-value=0.074, 0.072, and 0.075 respectively). On the other hand,

the animal lifestyle had slightly more significant effect on AGF community structure as follows:

251 The genus Neocallimastix was significantly more abundant in zoo-housed animals (p-

value=0.007), the genera Aklioshbomyces, Buwchfawromyces, and Pecoramyces were

significantly more abundant in wild animals (p-value=0.047, 0.028, and 0.014 respectively), and

the genera *Cyllamyces*, AL8, RH1, RH4, and RH6 were significantly more abundant in

domesticated animals (p-value=0.001, 0.001, 0.011, 0.018, and 0.054 respectively). Finally, for

individual animals species with enough replication in our study, the genera *Cyllamyces*, AL8,

and RH1 were significantly more abundant in *Bos taurus* (p-values=1.86E-11, 3E-5, and 2.27E-

9, respectively), the genera *Caecomyces* and RH5 were significantly more abundant in *Ovis aries*

(p-values=0.006, and 0.004 respectively), and the genera *Feramyces* and SK4 were significantly more abundant in *Ammotragus lervia* (p-values=0.002, and 0.0006, respectively). Further, some genera were only encountered in one animal, demonstrating a probable strong AGF genus-host preference. These genera include *Ghazallomyces* only encountered in axis deer, AL4 only encountered in domesticated sheep, MN3 only encountered in domesticated cow, and MN4 only encountered in domesticated goat.

265 Neocallimastigomycota isolation

A total of 216 AGF isolates were obtained from 21 animals (Table 3). Success in isolation and

267 maintenance of that large number of isolates was enabled by the implementation of various

techniques for isolation, and the development of a reliable storage procedure ⁵¹. Isolates obtained

belonged to 12 different genera (Table 3), six of which were exclusively isolated in this study,

and characterized in separate publications (Akhlioshbomyces, Ghazallomyces, Capellomyces,

271 Agriosomyces, Khoyollomyces (AL1), and Feramyces (AL6)^{28, 50}. In general, 1-3 AGF genera

were isolated per sample. Isolation efforts captured anywhere between 6.3% (1 of 16 genera) to

273 27.3% (3 of 11 genera) of AGF genera identified in a single sample using culture-independent

274 D1/D2 LSU gene-based analysis. However, these values are highly affected by the fact that

sequencing efforts are capable of identification of AGF genera present in extremely low levels of

276 relative abundance. Indeed, excluding rare taxa (those present at <1% abundance), the

culturability goes up to 10% (1 of 10 genera)-100% (2 of 2 genera).

We sought to determine how community structure and isolation efforts correlate, and whether obtaining isolates belonging to a specific genus could be predicted from the community structure of the sample. We observed a strong Pearson correlation (r=0.79) between the abundance of a certain genus in a sample and the frequency of its isolation. On the other hand,

282 the success of isolation of the most dominant member of the community was negatively affected 283 by the sample evenness (Pearson correlation coefficient = -0.87). Indeed, our ability to isolate the 284 novel genera Aklioshbmyces, Ghazallomycota, and Khyollomyces could be attributed to their 285 presence in high relative abundance in samples from which they were recovered (Table 3), as 286 opposed to their rarity/absence in other samples (Figure 3, 4). Within ubiquitous genera, we 287 observed that the abundance-success of isolation correlation described above is stronger for 288 monocentric taxa (Pearson correlation coefficients= 0.83, 0.96, 0.92, and 1 for *Pecoramyces*, 289 Feramyces, Neocallimastix, and Agriosomyces, respectively), while such relationship was much 290 weaker in polycentric taxa (Pearson correlation coefficients= 0.31, and 0.58 for *Orpinomyces*, 291 and *Anaeromyces*, respectively). However, the polycentric nature of these genera (ability to 292 propagate even in the absence of zoospore production, and the larger colony size on roll tubes) 293 enabled their isolation even when they constituted a minor fraction of the total community.

Discussion

295 LSU as a phylogenetic marker for AGF diversity surveys. We highlight and quantify the 296 advantages associated with the utilization of D1/D2 LSU as a phylomarker for the AGF when 297 compared to the currently utilized ITS1 region (Figures 1, 2). We also report on overcoming the 298 three main hurdles (lack of reference sequences from uncultured genera, correlating D1/D2 LSU 299 data to currently available ITS1 datasets, and amplicon length precluding utilization of Illumina 300 platform) associated with D1/D2 LSU use as a phylomarker. To address the lack of reference 301 LSU sequence data, we undertook a multi-year isolation effort to provide a comprehensive 302 D1/D2-LSU database from a wide range of AGF taxa, a necessary approach given the lack of 303 LSU sequence data from multiple historic taxa, unavailability of AGF in culture collections, and 304 difficulties in maintenance of this fastidious group of organisms. To correlate D1/D2 LSU data 305 to currently available ITS1 datasets and overcome amplicon length constrains, we utilized a 306 SMRT-PacBio sequencing approach to obtain sequences comprising the region spanning from 307 the start of the ITS1 region to the end of the D1/D2-LSU region in the rRNA locus (1400-1500 308 bp). In the process, we not only increased the representation of D1/D2-LSU sequences from all 309 cultured taxa, but also identified D1/D2-LSU sequences of yet-uncultured taxa previously 310 defined only by their ITS1 sequences (e.g. AL3, AL4, AL8, MN3, MN4, SK3, and SK4), as well 311 as defined 6 completely novel AGF candidate genera (RH1-RH6). Collectively, this dataset 312 (17,697 sequences of environmental D1/D2 LSU annotated by their taxonomy (Dataset 3), plus 313 116 Sanger-generated clone sequences and genomic rRNA loci sequences (Table 1 with 314 accession numbers) could pave the way for future D1/D2 LSU-based AGF diversity surveys. We 315 anticipate that additional sampling and culture-independent studies using the whole region, as

well as future isolation efforts will identify the corresponding D1/D2-LSU region for those few
yet-uncultured ITS1-defined lineages that we failed to capture in our study.

318 Single molecule real-time (SMRT) PacBio sequencing technology enables long read 319 sequencing by a single uninterrupted DNA polymerase molecule. The SMRT sequencing 320 protocol involves ligating hairpin adaptors to the ends of double-stranded DNA (PCR products in 321 the case of culture-independent studies), leading to the circularization of the DNA. This 322 subsequently allows the sequencing polymerase to pass around the molecule multiple times. The 323 re-sequencing by multiple passages increases sequence coverage thereby significantly reducing 324 error rates from initial values of up to 15%, to levels lower than 1%. Culture-independent studies in bacteria, archaea, and fungi ^{33, 52, 53, 54} have successfully applied the technology. We, here, 325 326 provide the basis for its application to culture-independent studies in anaerobic gut fungi. We 327 applied rigorous control to ensure the high quality of reads utilized to build the single molecule 328 consensus read sequences (by using a minimum threshold of 5 full passes and 99.95% predicted 329 accuracy), followed by pre-processing in Mothur to remove sequences with ambiguities or an 330 average quality score below 25. Also, we anticipate that future AGF diversity studies employing 331 PacBio sequencing of the D1/D2-LSU region (rather than the full ITS1-5.8S-ITS2-D1/D2 LSU 332 region) would be further enabled by the shorter amplicon length (~ 700 as opposed to ~ 1300 -333 1400 bp), as well as recent (e.g. Sequel II) and future anticipated improvements in SMRT 334 sequencing technology. 335 Discovery and characterization of novel AGF lineages. D1/D2 LSU-based diversity 336 assessment of 21 fecal samples identified multiple novel AGF candidate genera (Figure 3, 4),

five of which were subsequently isolated and described in separate publications (*Feramyces* 28 ,

338 *Aklioshbomyces, Agriosomyces, Ghazallomyces, and Khyollomyces*⁵⁰). These results clearly

339 demonstrate that the scope of AGF diversity is much broader than implied from prior studies. 340 This conclusion is in apparent disagreement with the recent work of Paul et al.¹⁷, where the 341 authors utilized a rarefaction-based approach on publicly available ITS1 AGF sequence data to 342 suggest that AGF sampling efforts have reached saturation. However, we argue that using a 343 rarefaction curve approach on publicly available datasets only elucidates coverage within 344 samples already in the database, and not the broader AGF diversity in nature. Many prior studies 345 have used relatively low throughput sequencing technologies, and repeatedly sampled few 346 domesticated animals, and such pattern would result in encountering highly similar populations 347 between different studies. We attribute the discovery and characterization of a wide range of 348 novel AGF taxa within our dataset to sampling previously unsampled animal hosts, and the use 349 of high-throughput sequencing that enabled access to rare members of the AGF community. 350 Multiple novel AGF genera were isolated from animals previously unsampled for AGF diversity, 351 e.g. Aklioshbomyces from white-tailed deer where it represented 98.5% of the community, 352 Ghazallomyces from axis deer where it represented 27.8% of the community, and Feramyces 353 from an aoudad sheep sample where it represented 55.3% of the community. It is notable that 354 many of these novel taxa were only encountered in wild herbivores. Whether this novelty is a 355 reflection of a lifestyle selecting for specific taxa, or a reflection of simply lack of prior sampling 356 of wild animals due to logistic difficulties remains to be seen. This clearly demonstrates that 357 novel AGF taxa remain to be discovered by sampling hitherto unsampled/poorly sampled animal 358 hosts.

Further, a significant fraction of novel AGF candidate genera identified were present in extremely low relative abundance. Such pattern suggests the presence of numerous novel AGF taxa that appear to predominantly exist in relatively low abundance possibly as dormant

362 members of the AGF community in the herbivorous gut. The discovery and characterization of 363 the rare members of AGF community could significantly expand the scope of AGF diversity in 364 nature. The dynamics, rationale for occurrence, mechanisms of maintenance, putative role in 365 ecosystems, and evolutionary history of rare members of the community are currently unclear. It 366 has been suggested that a fraction of the rare biosphere could act as a seed bank of functional 367 redundancy that aids in ecosystem response to periodic (e.g. occurring as part of growth of the 368 animal host, or due to seasonal changes in feed types) or occasional (i.e. due to unexpected 369 disturbances) changes in the gut *in-situ* conditions. Regardless, such pattern highlights the value 370 of deeper sampling (to capture rare biosphere), as well as more extensive time-series, rather than 371 snapshot, sampling to capture patterns of promotion and demotion of members of the AGF 372 community within the lifespan of an animal.

373 The value of AGF isolation efforts. The strict anaerobic nature of AGF necessitates the 374 implementation of special techniques for their isolation and maintenance ^{55, 56}. Further, while 375 several storage methods based on cryopreservation have been proposed ⁵⁷, the decrease in 376 temperature to the ultra-low values and the incidental O₂ exposure during revival of the 377 cryopreserved strains were shown before to be detrimental for some isolates. The lack of reliable 378 long-term storage procedures often necessitates frequent subculturing of strains (every 3-4 days), 379 which often leads to either the production of sporangia that do not differentiate to zoospores, or the outright failure to produce sporangia ⁵⁸. 380

Through a multi-year effort, we were successful in obtaining 216 isolates representing twelve AGF genera. We attribute our success to using multiple strategies (enrichment on multiple carbon sources, and paying special attention to picking colonies of different shapes and sizes, and to picking several colonies of the same shape, as representatives of different genera are

385 known to produce colonies with very similar macroscopic features), but, more importantly, to 386 using a wide range of samples (with varying host lifestyle, gut type, and animal phylogeny). The 387 success of isolation of a certain genus was, in general, attributed to its abundance in the sample 388 (Pearson correlation coefficient=0.79), especially for monocentric genera (e.g. *Pecoramyces*, 389 *Feramyces*, *Neocallimastix*, and *Agriosomyces*), and was negatively correlated to the sample 390 evenness (Pearson correlation coefficient= -0.87). It remains to be seen if this is true and 391 reproducible for all samples and across laboratories. More efforts are certainly needed to develop 392 targeted isolation strategies for specific taxa that we failed to obtain in pure cultures despite our 393 best effort and despite their abundance in their respective sample (e.g. SK4 in one of the aoudad 394 sheep samples, and RH5 in the domesticated sheep and the axis deer samples). 395 In conclusion, our results establish the utility of D1/D2 LSU and PacBio sequencing for 396 AGF diversity surveys, and the culturability of a wide range of AGF taxa, and demonstrate that

397 wild herbivores represent a yet-untapped reservoir of AGF diversity.

Experimental Procedures

399	Samples. Fecal Samples were obtained from six domesticated, six zoo-housed, and nine wild
400	animals (Table 2). The host animals belonged to the families Bovidae (11), Cervidae (6),
401	Equidae (3), and Camelidae (1). The dataset encompassed some replicates from few animal
402	species sometimes with lifestyle variations within a single animal species: Bos taurus (n=2;
403	domesticated cow, and domesticated longhorn cattle), Ovis aries (n=2; domesticated sheep and
404	wild mouflon ram), Capra aegagrus (n=3; domesticated goat, wild Boer goat, and zoo-housed
405	dwarf goat), and Ammotragus lervia (n=2; Aoudad Sheep) (Table 2). Samples from domesticated
406	animals were obtained from Oklahoma State University and surrounding farms between
407	September 2016 and May 2018. Samples from the Oklahoma City Zoo were obtained in April
408	2019. For samples from wild herbivores, we enlisted the help of hunters in four separate hunting
409	expeditions in Sutton, Val Verde, and Coke counties, Texas (April 2017, July 2017, and April
410	2018), and Payne County, Oklahoma (October 2017). Appropriate hunting licenses were
411	obtained and the animals were shot either on private land with the owner's consent or on public
412	land during the hunting season. All samples were stored on ice and promptly (within 20 minutes
413	for domesticated samples, within 1 hour for zoo samples, and within 24 hours for samples
414	obtained during hunting trips) transferred to the laboratory. Upon arrival, a portion of the sample
415	was immediately used for setting enrichments for isolation efforts, while the rest was stored at -
416	20°C for DNA extraction.

417 Development of D1/D2 LSU locus as a phylogenetic marker.

418 *A. Amplification of the ITS1-5.8S rRNA-ITS2-D1/D2 LSU from Neocallimastigomycota isolates.*

419 Biomass was harvested from 10 ml of 2-4-day old cultures and crushed in liquid nitrogen. DNA

420 was extracted from the ground fungal biomass using DNeasy PowerPlant Pro Kit (Qiagen,

421 Germantown, Maryland) according to the manufacturer's instructions (Youssef et al. 2013). A 422 PCR reaction targeting the region encompassing ITS1, 5.8S rRNA, ITS2, and D1/D2 region of 423 the LSU rRNA' (Figure 6) was conducted using the primers ITS5-NL4²³. The PCR protocol 424 consisted of an initial denaturation for 5 min at 95 °C followed by 40 cycles of denaturation at 425 95 °C for 1 min, annealing at 55 °C for 1 min and elongation at 72 °C for 2 min, and a final 426 extension of 72 °C for 20 min. PCR amplicons were purified using PureLink® PCR cleanup kit 427 (Life Technologies, Carlsbad, California), followed by cloning into a TOPO-TA cloning vector 428 according to the manufacturer's instructions (Life Technologies, Carlsbad, California). Clones 429 (n=1-12 per isolate) were Sanger sequenced at the Oklahoma State University DNA sequencing 430 core facility.

431 *B. Amplification of the ITS1-5.8S-ITS2-D1/D2 LSU from environmental samples.* Fecal material

432 from different animals (0.25-0.5 g) were crushed in liquid nitrogen and total DNA was extracted

433 from the ground sample using DNeasy PowerPlant Pro Kit (Qiagen, Germantown, Maryland)

434 according to the manufacturer's instructions (Youssef et al. 2013). Extracted DNA was then used

435 as a template for ITS1-5.8S-ITS2-D1/D2 LSU PCR amplification using ITS5 forward primer and

436 the AGF-specific reverse primer GG-NL4²⁴. Primers were barcoded to allow PacBio sequencing

437 and multiplexing (Table S2). Amplicons were purified using PureLink® PCR cleanup kit (Life

438 Technologies, Carlsbad, California), quantified using Qubit® (Life Technologies, Carlsbad,

439 California), pooled, and sequenced at Washington State University core facility using one cell of

the single molecular real time (SMRT) Pacific Biosciences (PacBio) RSII system.

441 *C. Environmental PacBio-generated sequences quality control.* We performed a two-tier quality

442 control protocol on the generated sequences. First, the raw reads were processed according to

443 PacBio published protocols to obtain single molecule consensus reads. Second, we used rigorous

sequence quality control in Mothur ⁵⁹ to remove any sequences with low quality from subsequent
analysis.

446 For Raw reads processing, the official PacBio pipeline (RS_Subreads.1)

447 (http://files.pacb.com/software/smrtanalysis/2.2.0/doc/smrtportal/help/!SSL!/Webhelp/CS_Prot_

448 RS_Subreads.htm) was utilized. Raw reads were filtered based on the minimum read length and

449 minimum read quality. The passing reads were then processed with the PacBio

450 RS_ReadsOfInsert protocol

451 (http://files.pacb.com/software/smrtanalysis/2.2.0/doc/smrtportal/help/!SSL!/Webhelp/CS_Prot_

452 <u>RS_ReadsOfInsert.htm</u>) for generating single-molecule consensus reads from the insert template.

453 Consensus reads had a minimum of 5 full passes, 99.95% predicted accuracy, and 1000 bp insert

454 length. The resulting consensus reads had a mean number of passes of 20, mean read length of

455 insert of 1429 bp, and mean polymerase read quality of 0.99.

Sequence quality control procedures were subsequently conducted in Mothur ⁵⁹ to assess 456 457 the quality of the generated consensus reads utilizing stringent protocols previously suggested for 458 assessing bacterial, archaeal, and fungal diversity for similar sized amplicons ^{33, 52, 53, 54}. Reads 459 were filtered in Mothur using trim.seqs to remove reads longer than 2000 bp, reads with average 460 quality score below 25, reads with ambiguous bases, reads not containing the correct barcode 461 sequence, reads with more than 2 bp difference in the primer sequence, and reads with 462 homopolymer stretches longer than 12 bp. Reads with the primer sequence in the middle were 463 identified by performing a standalone Blastn-short using the primer sequence as the query, and 464 were subsequently removed using the remove seqs command in Mothur. 465 A mock community (constituted of equal concentration of PCR products of 5 different

466 strains (Aklioshbomyces papillarum strain WT2, Feramyces austinii isolate DS10,

467 *Liebetanzomyces* sp. isolate Cel1A, *Piromyces* sp. isolate A1, and *Piromyces* sp. isolate Jen1) 468 from our culture collection and for which we have obtained at least 5 Sanger clone sequences) 469 was also sequenced. To establish whether the above approaches for overall read- and sequence-470 based quality control are adequate, we compared PacBio-generated mock sequences to the 471 corresponding Sanger-generated clone sequences. The median percentage similarity between 472 PacBio-generated sequences affiliated with a certain strain and the Sanger-generated clone 473 sequences obtained for that strain $(99.05\pm0.6 \text{ to } 99.64\pm0.47)$ were not significantly different 474 from the median percentage similarities between different clones of the same strain (98.91±0.6 to 475 99.72±0.47) (Student t-test p-value>0.1) attesting to the adequacy of the above quality control 476 measures in removing low quality sequences. 477 D. A D1/D2 LSU reference database for cultured and yet-uncultured AGF taxa. A reference 478 D1/D2-LSU sequence database for all Neocallimastigomycota cultured genera present in our 479 culture collection was created via amplification, cloning, and sequencing of the ITS1-5.8S-ITS2-480 D1/D2 LSU allowing for a direct correlation and cross-referencing of both regions. To obtain 481 D1/D2 LSU sequences representing yet-uncultured candidate genera previously defined by ITS1 482 sequence data ^{3, 5, 13, 17, 46}, the ITS1 region from the PacBio-generated ITS1-5.8S-ITS2-D1/D2 483 LSU environmental amplicons was extracted in Mothur using the pcr.seqs command with the 484 sequence of the MNGM2 reverse primer and the flag rdiffs=2 to allow for 2 differences in primer 485 sequence. The trimmed sequences corresponding to the ITS1 region were compared, using 486 blastn, to a manually curated Neocallimastigomycota ITS1 database encompassing all known 487 cultured genera, as well as yet-uncultured taxa previously identified in culture-independent studies ^{3, 5, 13, 17, 46} (Figure 6). Sequences were classified as their first hit taxonomy if the 488 489 percentage similarity to the first hit was >96% and the two sequences were aligned over >70% of

the query sequence length. A taxonomy file was then created that contained the name of each
sequence in the PacBio-generated environmental dataset and its corresponding taxonomy and
was used for assigning taxonomy to the D1/D2 LSU sequence data.

493 E. Comparison of D1/D2-LSU versus ITS1 as phylogenetic markers. We used the dataset of full

494 length PacBio-generated sequences described above, in addition to 116 Sanger-generated clone

495 sequences from this study and previous studies ^{23, 28, 29, 49}, as well as genomic rRNA loci from

496 two Neocallimastigomycota genomes (Pecoramyces ruminantium strain C1A, and

497 *Neocallimastix californiae* strain G1) ^{36, 43} in which the entire rrn operon sequence data is

498 available to compare the ITS1 and D1/D2-LSU regions with respect to heterogeneity in length

and intra-genus sequence divergence. For every sequence, the ITS1, and the D1/D2-LSU regions

500 were bioinformatically extracted in Mothur using the pcr.seqs command (with the reverse primer

501 MNGM2, and the forward primer NL1, for the ITS1, and the D1/D2-LSU regions, respectively)

and allowing for two differences in the primer sequence. The trimmed sequences (both ITS1 and

503 D1/D2-LSU) were then sorted into files based on their taxonomy such that for each genus/taxon

504 two fasta files were created, an ITS1 and a D1/D2-LSU. These fasta files were then used to

505 compare length heterogeneity, and intra-genus sequence divergence as follows. Sequences

506 lengths in each fasta file were obtained using the summary.seqs command in Mothur. Intra-genus

507 sequence divergence values were obtained by first creating a multiple sequence alignment using

508 the MAFFT aligner ⁶⁰, followed by generating a sequence divergence distance matrix using the

509 dist.seqs command in Mothur. Box plots for the distribution of length and sequence divergence

510 were created in R.

511 AGF Diversity assessment using D1/D2 LSU locus.

512	A. Phylogenetic placement. The majority of the D1/D2-LSU sequences bioinformatically
513	extracted from environmental sequences were assigned to an AGF genus as described above.
514	D1/D2-LSU sequences that could not be confidently assigned to an AGF genus were
515	sequentially inserted into a reference LSU tree to assess novelty. Further, the associated ITS1
516	sequences (obtained from the same amplicon) were similarly inserted into a reference ITS1 tree
517	for confirmation. Sequences were assigned to a novel candidate genus when both loci (LSU and
518	ITS1) cluster as novel, independent genus-level clades with high (>70%) bootstrap support in
519	both trees.
520	B. Genus and species level delineation. Genus level assignments were conducted via a
521	combination of similarity search and phylogenetic placement as described above. We chose not
522	to depend on sequence divergence cutoffs for OTU delineation at the genus level since some
523	genera exhibit high sequence similarity between their D1/D2-LSU sequences (e.g.
524	Liebetanzomyces, Capellomyces, and Anaeromyces D1/D2-LSU sequence divergence ranges
525	between 1.8-2.5%), while other genera are highly divergent (e.g. Piromyces intra-genus sequence
526	divergence cutoff of the D1/D2-LSU region ranges between 0-5.7%), and as such "a one size fits
527	all" approach should not be applied. On the other hand, a similar approach for OTUs delineation
528	at the species equivalent level is problematic due to uncertainties in circumscribing species
529	boundaries, and inadequate numbers of species representatives in many genera. Therefore, for
530	OTU delineation at the species equivalent level, we reverted to using a sequence divergence
531	cutoff. Historically, cutoffs of 3% 16 to 5% 3 were used for ITS1-based species equivalent
532	delineation. However, D1/D2-LSU sequence data are more conserved when compared to LSU
533	data in the Neocallimastigomycota ^{15, 26, 27, 28, 29, 30, 50} , as well as other fungi ¹⁹ . To obtain an
534	appropriate species equivalent cutoff, we used the 116 Sanger-generated clone sequences from

535	this study and previous studies ^{23, 28, 29, 49} , as well as genomic rRNA loci from two
536	Neocallimastigomycota genomes where the entire ribosomal operon sequence is available
537	(Pecoramyces ruminantium strain C1A, and Neocallimastix californiae strain G1) ^{36,43} . The
538	ITS1 and D1/D2-LSU regions were bioinformatically extracted and sorted to separate fasta files.
539	Sequences in each file were then aligned using MAFFT ⁶⁰ and the alignment was used to create a
540	distance matrix for every possible pairwise comparison using dist.seqs command in Mothur. The
541	obtained pairwise distances for the ITS1, and the D1/D2-LSU regions were then correlated to
542	obtain values of D1/D2-LSU sequence divergence cutoffs corresponding to the 3-5% range in
543	ITS1. This was equivalent to 2.0-2.2%, and hence, for this study, a cutoff of 2% was used for
544	OTU generation at the species equivalent level using the D1/D2-LSU region.
545	C. Diversity and community structure assessments. Genus and species equivalent OTUs
546	generated as described above were used to calculate alpha diversity indices (Chao and Ace
547	richness estimates, Shannon diversity index, Simpson evenness index) for the different samples
548	studied using the summary.seqs command in Mothur. A shared OTUs file created in Mothur
549	using the make.shared command was used to calculate Bray-Curtis beta diversity indices
550	between different samples (using the summary.shared command in Mothur). The shared OTUs
551	file was also used as a starting point for ranking the samples based on their diversity using both
552	an information-related diversity ordering method (Renyi generalized entropy), and an expected
553	number of species-related diversity ordering method (Hulbert family of diversity indices) (Table
554	2). For community structure visualization, Bray Curtis indices at the genus level were also used
555	to perform non-metric multidimensional scaling using the metaMDS function in the Vegan
556	package in R. Also, the percentage abundance of different genera across the samples studied
557	were used in principal components analysis using the prcomp function in the labdsv package in

R. Ordination plots were generated from the two analyses (NMDS and PCA) using the ordiplotfunction.

560 D. Statistical analysis: Correlations of the diversity estimates to animal host factors including the

- animal lifestyle (domesticated, zoo-housed, wild), and the animal host families (Bovidae,
- 562 Cervidea, Equidae, Camelidae) were calculated using χ^2 -contingency tables followed by
- 563 measuring the degree of association using Cramer's V statistics as detailed before ³. In addition,
- to identify factors impacting AGF diversity, Student t-tests were used to identify significant
- 565 differences in the above alpha diversity estimates based on animal lifestyle (zoo-housed,
- 566 domesticated, wild), and host phylogeny (families Bovidae, Equidae, Cervidae). To test the
- 567 effect of the above host factors on the AGF community structure, Student t-tests were used to

identify significant associations between specific AGF taxa and animal lifestyle (zoo-housed,

569 domesticated, wild) or host family (families Bovidae, Equidae, Cervidae).

570 **Isolation efforts.**

571 Fecal samples (either freshly obtained, or stored at -20°C in sterile, air-tight plastic tubes) were

572 used for isolation. Care was taken to avoid sample repeated freezing and thawing. Samples were

- 573 first enriched by incubation for 24 h at 39°C in rumen-fluid-cellobiose (RFC) medium
- 574 supplemented with antibiotics (50 μg/mL kanamycin, 50 μg/mL penicillin, 20 μg/mL

575 streptomycin, and 50 μ g/ mL chloramphenicol) ^{27, 28, 29, 50, 51}. Subsequently, enrichments were

serially diluted by adding approximately 1 ml of enriched samples to 9 mL of RF medium

577 supplemented with 1% cellulose or a mixture of 0.5% switchgrass and 0.5% cellobiose. Since

578 fungal hyphae and zoospores are usually attached to the coarse particulates in the enrichment,

579 serial dilutions were conducted using Pasteur pipettes rather than syringes and needles, as the

580 narrow bore of the needle prevented the fecal clumps from being transferred. Serial dilutions up

to a 10⁻⁵ dilution were incubated at 39^oC for 24–48 h. Dilutions showing visible signs of growth 581 582 (clumping or floating plant materials, a change in the color of cellulose, and production of gas 583 bubbles) were then used for the preparation of roll tubes ^{55, 56} on RFC agar medium. At the same 584 time, and as a backup strategy in case the roll tubes failed to produce visible colonies, the 585 dilution tubes themselves were subcultured and transferred to fresh medium with the same 586 carbon source. Single colonies on roll tubes were then picked into liquid RFC medium, and at 587 least three rounds of tube rolling and colony picking were conducted to ensure purity of the 588 obtained colonies. To maximize the chances of obtaining isolates belonging to different genera, 589 special attention was given, not only to picking colonies of different shapes and sizes, but also to 590 picking several colonies of the same shape, as representatives of different genera could produce 591 colonies with very similar macroscopic features. Isolates were maintained by biweekly 592 subculturing into RFC medium. For long-term storage, cultures were stored on agar medium 593 according to the procedure described by Calkins et al. ⁵¹. 594 **Data accession**. Sanger-generated clone sequences from pure cultures were deposited in 595 GenBank under accession numbers MT085665 - MT085741. SMRT-generated sequences were 596 deposited at DDBJ/EMBL/GenBank under the Bioproject accession number PRJNA609702, 597 Biosample accession numbers SAMN14258225, and Targeted Locus Study project accession 598 KDVX00000000. The version described in this paper is the first version, KDVX01000000. 599 600 Acknowledgements: This work has been funded by the NSF-DEB grant 1557102 to N.H.Y. and 601 M.S.E.

*GenBank Accession numbers are provided for Sanger sequenced clones from all fungal isolates. PacBio-generated datasets are present in GenBank in the Bioproject accession number PRJNA609702, Biosample accession numbers SAMN14258225, and Targeted Locus Study project accession KDVX00000000. FASTA files of ITS1-5.8S-ITS2-D1/D2 LSU region, as well as bioinformatically extracted ITS1 region and D1/D2 LSU regions are provided as supplementary documents (Datasets 1-3) ** Sequences extracted from a genomic assembly

610 Table 2. Animals sampled in this study, numbers of sequences obtained (N), number of observed OTUs, and various diversity indices both at the species 611 equivalent (0.02) and the genus levels

Pere David's deer	Cervidae	Zoo	169	7	6	10	6.5	17	7.8	0.32	0.36	0.96	0.88	6.7	10.5	0.96	0.99
White-tail deer	Cervidae	Wild	946	23	6	23	7.5	23.4	14.7	0.06	0.17	0.75	0.07	2.8	1	1	1
Zebra	Equidae	Zoo	2067	55	11	73	13	85.4	15	0.03	0.15	1.10	0.76	6	6	0.99	1

612 *: N refers to the number of sequences obtained for each of the animals sampled.

613 **: Diversity ranking is the average rank obtained using both an information-related diversity ordering method (Renyi generalized

614 entropy), and an expected number of species-related diversity ordering method (Hulbert family of diversity indices). Samples are 615 ranked from the least diverse (rank 1) to the most diverse (rank 21).

616 ***: Coverage refers to the Good's coverage index.

AGF genus	Source	Number of isolates	% Abundance in that animal			
4	Mouflon	4	3.28			
Agriosomyces	Boer goat	1	8.5			
Aklioshbomyces	White-tail deer	9	98.95			
	Domesticated cow	4	0.68			
	domesticated goat	12	2.44			
Anaeromyces	American bison	4	1.63			
	Alpaca	4	17.01			
Caecomyces	Fallow deer	1	0.44			
Capellamyces	Boer goat	5	ND			
Г	Aoudad sheep (1)	5	55.31			
Feramyces	Fallow deer	1	4.46			
Ghazallomyces	Axis deer	11	27.79			
Khyollomyces	Zebra	16	74.5			
	Dwarf goat	7	97.88			
N. 11	Fallow deer	10	1.24			
Neocallimastix	Pere David's deer	10	54.44			
	American elk	12	72

629 Table 3. Number and sources of isolates obtained in thus study.

630

632 Figures Legends

- 633 Figure 1. Box and whisker plots showing the variability in intra-genus length (A-B) and
- 634 sequence divergence cutoff (C-D) for the ITS1 (A, C) and D1/D2 LSU (B, D) regions. A cartoon
- of the rRNA locus is shown on top. Genera and candidate genera with at least 5 sequences
- encompassing the full region "ITS1-5.8S-ITS2-D1/D2 LSU" were used to construct this plot as
- detailed in the methods section. The candidate genera AL4, MN3, MN4, RH3, RH6, and SK3
- had only a few sequence representatives (1-3) and so are not included in the plot.
- 639 Figure 2. Box and whisker plots showing the variability in intra-strain length (A-B) and
- 640 sequence divergence cutoff (C-D) for the ITS1 (A, C) and D1/D2 LSU (B, D) regions.
- 641 Figure 3. AGF genera distribution across the animal studied. (A) Percentage abundance of AGF

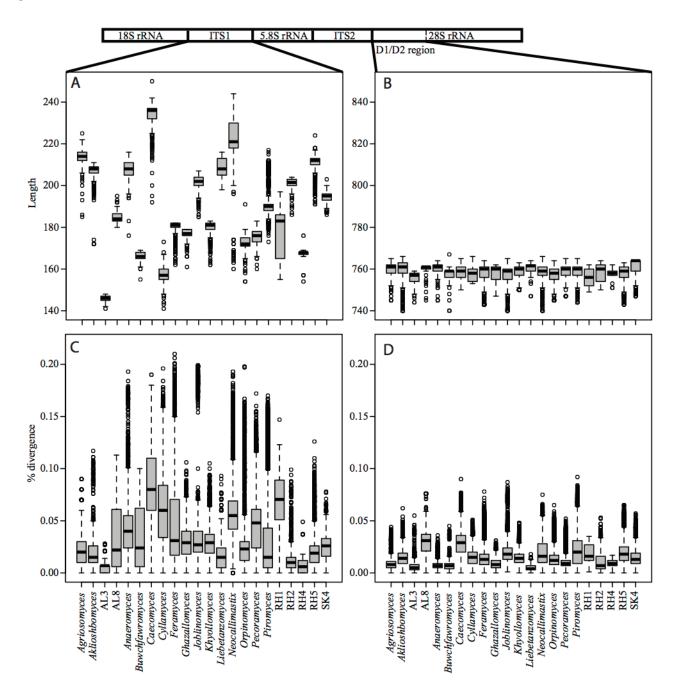

642 genera in the animals studied. The tree is intended to show the relationship between the animals

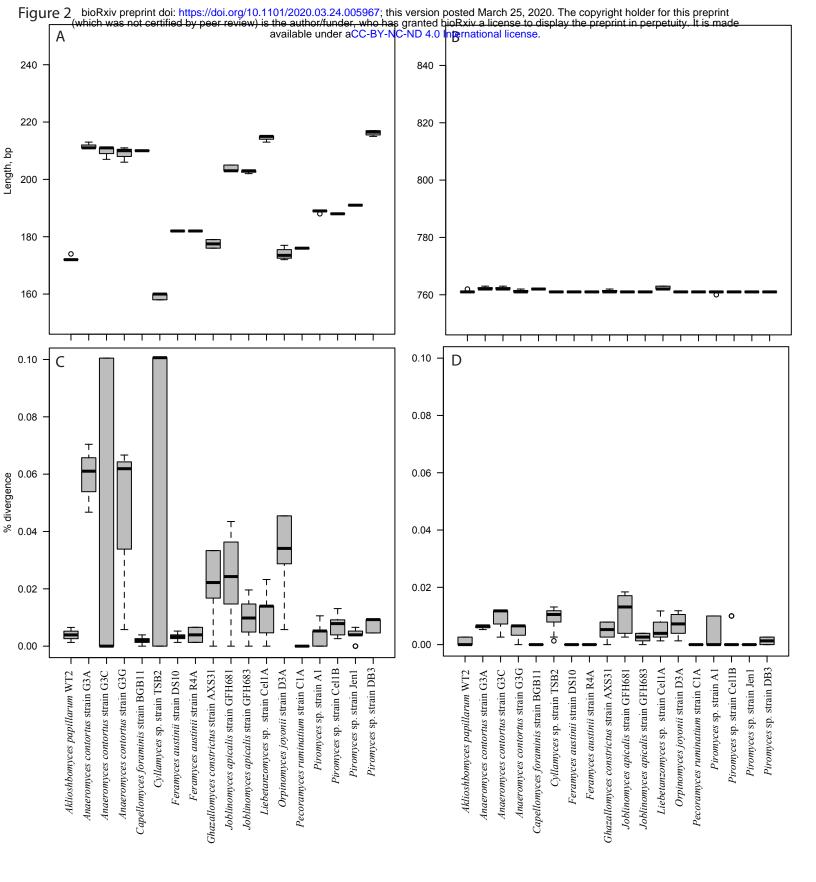

- 643 and is not drawn to scale. Host phylogeny (family), lifestyle, and gut type are shown for each
- animal. The X-axis shows the percentage abundance of AGF genera. (B) Rank abundance curves
- are displayed for each animal showing a distribution pattern in which a few genera (1-5)
- 646 represent the majority (>10%) of the sequences obtained.
- 647 **Figure 4.** (A) Phylogenetic tree constructed using the D1/D2 LSU sequences of representatives
- 648 of each of the 28 genera/candidate genera identified in this study. Sequences were aligned using
- the MAFFT aligner and maximum likelihood tree was constructed in FastTree ^{61, 62}. Bootstrap
- values are based on 100 replicates and are shown for branches with >50% bootstrap support.
- 651 Genera with cultured representatives are shown in black, uncultured candidate genera identified
- 652 in previous ITS1-based studies are shown in green, while the 6 novel genera identified in the
- 653 current study are shown in red. The distribution of each of these genera/candidate genera in the
- animals studied is shown as a heatmap on the right. (B) AGF genera distribution patterns. The

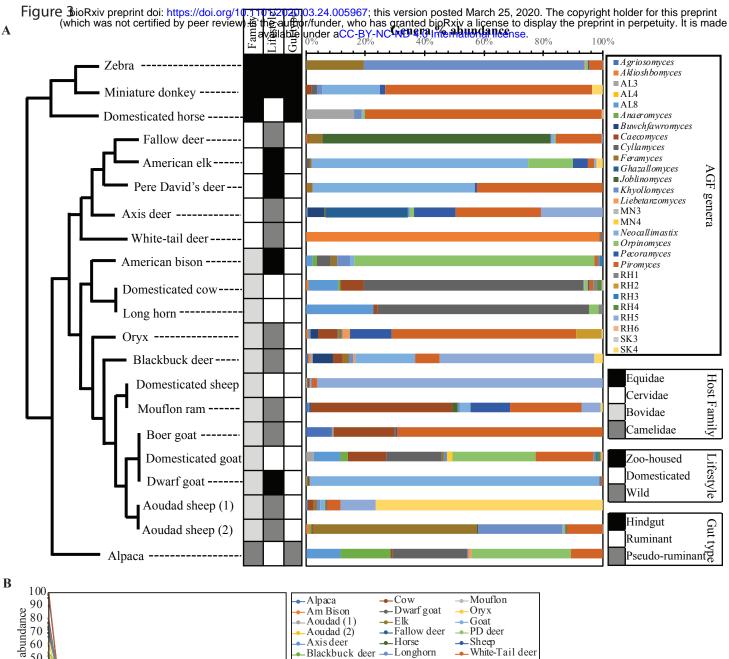

655	total number of animals harboring each of the genera identified in this study is shown on the Y-
656	axis, with the different colored stacked bars reflecting the number of animals where the genus
657	was the most abundant member, occurred with high (>5%) abundance, occurred with medium
658	(1-5%) abundance, or occurred with low (<1%) abundance. AGF genera are classified into one
659	of the five distribution patterns shown on top of the graph using empirical cutoffs for ubiquity
660	(presence in at least 50% of the animals studied, shown as the dotted line across the bottom bar
661	chart), as well as the fraction of animals where the genus abundance was above 1% (shown as
662	the top bar chart).
663	Figure 5. Nonmetric multidimensional scaling based on pairwise Bray-Curtis dissimilarity
664	indices at the genus level. Samples are shown as symbols and displayed in black text while AGF
665	genera are shown as '+' and displayed in red text. (A) Symbols reflect lifestyle with domesticated
666	animals shown as white squares, zoo-housed animals shown as grey squares, and wild animals
667	shown as black squares. (B) Symbols reflect animal host phylogeny with family Bovidae shown
668	as squares, family Cervidae shown as circles, family Equidae shown as hexagons, and family
669	Camelidae shown as a star. Abbreviations: Am Bison, American bison; Ax deer, Axis deer; B
670	goat, Boer goat; Bb deer, Blackbuck deer; Dw Goat, Dwarf goat; Fa deer, Fallow deer; Min Don,
671	Miniature donkey; PD deer, Pere David's deer; WT deer, White-tail deer.
