13 **Abstract**

14 The mouse preimplantation embryo is a paradigm for discovery of the molecular principles
15 governing formation of specific cell types during development. We show that conditions
16 commonly used for *ex vivo* culture of preimplantation development are themselves antagonistic
17 to a pathway that is critical for blastocyst lineage commitment.

18

19 **Introduction**

20 Knowledge of the mechanisms that drive lineage decisions during mouse preimplantation
21 development can significantly impact fields of stem cell and reproductive biology. Studies of the
22 first three days of development have shown that the initially totipotent blastomeres of the mouse
23 embryo adopt one of three cell fates by the blastocyst stage: trophoblast (future placenta),
24 primitive endoderm (future yolk sac endoderm), or epiblast (future fetus and additional
25 extraembryonic tissues). Notably, the ultimate ratio of these three cell types is largely invariant
26 among embryos, indicating that robust regulatory mechanisms exist. Remarkably, lineage
27 specification is even achieved in incubator-grown preimplantation embryos, raised outside of the
28 maternal environment, suggesting that the most critical regulatory mechanisms are intrinsic to
29 the embryo. However, the possibility that culture conditions influence the embryo's signaling
30 environment cannot be formally excluded.

31

32 Major insight into the roles of cell signaling in preimplantation cell fate decisions has been
33 provided by studies of the Fibroblast Growth Factor (FGF) signaling pathway (reviewed in
34 Soszyńska *et al.*, 2019). Culturing embryos in FGF4 and Heparin (referred to as FGF4,
35 hereafter) causes blastomeres to adopt primitive endoderm, over epiblast, fate (Yamanaka *et*
36 *al.*, 2010). Importantly, the balance between primitive endoderm and epiblast fates is achieved
37 through the exquisite regulation of the specific dose of FGF signaling experienced by the
38 embryo as it develops (Krawchuk *et al.*, 2013).

39

40 The ability to culture preimplantation embryos in the presence of small molecule inhibitors or
41 agonists of signaling has enabled discovery of the gene regulatory networks crucial for early
42 mammalian development. For example, artificially tweaking the level of FGF/ERK signaling in
43 embryos lacking specific transcription factors (*i.e.* transcription factor gene knockouts), can
44 reveal whether transcription factors function upstream, downstream, or independently of
45 FGF/ERK signaling. In addition, these assays have provided new insights into the
46 developmental mechanisms in other mammals, including humans (Kuijk *et al.*, 2012; Roode *et*
47 *al.*, 2012; Boroviak *et al.*, 2015; Piliszek *et al.*, 2017).

48

49 Culturing mouse embryos in agonists and antagonists of FGF/ERK signaling is routine, yet we
50 note that this is typically performed in amino acid-containing KSOM medium containing 1 mg/mL
51 bovine serum albumin (BSA). This raises the possibility that a bovine serum-derived impurity
52 could alter the embryonic signaling environment. However, this possibility has not been
53 explored.

54

55 **Results and Discussion**

56 To better understand the embryonic signaling environment, we cultured embryos in the
57 presence of 1 mg/mL polyvinyl alcohol (PVA), a synthetic macromolecule that can replace BSA
58 in supporting blastocyst development (KSOM without BSA hereafter) (Biggers *et al.*, 1997; Jang
59 *et al.*, 2007), and provide a more defined medium. In embryos cultured for 66 hours starting
60 from the 2-cell stage (embryonic day E1.5) in KSOM without BSA, we observed quantitatively
61 normal specification of trophectoderm, inner cell mass, epiblast and primitive endoderm cell
62 types (Fig. 1A-C). This observation is consistent with prior evidence that PVA supports
63 development of mouse blastocysts *in vitro* (Biggers *et al.*, 1997).

64

65 Having established that KSOM without BSA supports blastocyst lineage specification, we then
66 evaluated the sensitivity of blastocysts to exogenous FGF4 in the absence of BSA. Remarkably,
67 embryos cultured in KSOM without BSA were sensitive to much lower doses of FGF4 (150
68 ng/mL) than embryos grown in the presence of BSA (Fig. 1D, E). Higher sensitivity to FGF4 is
69 due to the absence of BSA, rather than the presence of PVA since BSA antagonized the effects
70 of FGF4 signaling in the presence of PVA (Fig. 1E). Surprisingly, a dose as low as 25 ng/mL
71 FGF4 was capable of driving epiblast cells to express primitive endoderm genes when embryos
72 were cultured in KSOM without BSA (Fig. 1F), which is 20-40 times lower than the FGF4 dose
73 typically used to convert epiblast to primitive endoderm. This observation suggests that higher
74 doses of FGF4 are super-physiological. These observations strongly suggest that BSA is
75 antagonistic to changes in embryonic cell fates induced by exogenous FGF4.

76

77 We do not yet understand the mechanism by which BSA interferes with signaling induced by
78 exogenous FGF4. There is precedent that BSA can bind heparin, as well as extracellular
79 signaling pathway members (Francis, 2010). We note that BSA does not appear to interfere with
80 endogenous signaling, evidenced by the apparently normal lineage specification occurring in
81 embryos cultured in KSOM with BSA. This could be because BSA in culture cannot penetrate
82 the blastocyst to interfere with the highly localized FGF signaling occurring within the inner cell
83 mass. We therefore caution that the routine supplementation with BSA could complicate studies
84 aimed at understanding the roles and doses of signaling pathways in preimplantation
85 development.

86

87 **Materials and Methods**

88

89 **Mouse Stains**

90 All animal care and husbandry for this study was performed in accordance with the guidelines
91 established by the Institutional Animal Care and Use Committee at Michigan State University.
92 Embryos in this study were obtained by timed natural matings of CD-1 mice (Charles River)
93 which utilized males from 6 weeks to 6 months old, and females from 4 weeks to 3 months old.

94

95 **Embryo collection and culture**

96 CD-1 embryos were collected at noon the day after observing the presence of a copulation plug
97 (E1.5) by flushing oviducts with M2 medium (Millipore-Sigma, MR015D). Prior to transfer to the
98 culture incubator, embryos were washed through 3x drops of embryo culture medium (KSOM
99 with BSA (Millipore-Sigma, MR121D) or KSOM without BSA (Millipore-Sigma, MR107D) to
100 remove M2 medium. KSOM without BSA was supplemented with 1 mg/mL PVA from a stock of
101 100 mg/mL PVA in water (Millipore-Sigma, P8136). Where indicated heparin (Millipore-Sigma,
102 H3149) and FGF4 (R&D Systems, 235F4025) were added to embryo culture medium. Embryos
103 were cultured under ES cell grade mineral oil (Millipore-Sigma, ES005C) for 66 hours at 37°C
104 and 5% CO₂. Embryo culture medium under mineral oil was equilibrated in the embryo culture
105 incubator for at least 18 hours prior to the addition of embryos.

106

107 **Immunofluorescence and Confocal Microscopy**

108 Embryos were fixed in 4% formaldehyde (Polysciences) for 10 minutes then immediately
109 permeabilized for 30 minutes in 0.5% Triton X-100 (Millipore-Sigma, T8787) diluted in PBS.
110 Embryos were stored in blocking buffer (10% FBS (Hyclone), 0.1% Triton X-100, PBS) for at
111 least 18 hours and no longer than 5 days prior to incubation with primary antibodies. Primary
112 antibodies were diluted in blocking buffer to the following concentrations: rabbit IgG anti-Nanog
113 (Reprocell, RCAB002P) 1:400, goat IgG anti-SOX17 (R&D systems, AF1924) 1:2000 and
114 applied overnight at 4°C. DyLight 488 (Jackson ImmunoResearch, 805485180) and Cyanine3
115 (Jackson ImmunoResearch, 711165152) conjugated antibodies targeting IgG were diluted at

116 1:400 in blocking buffer and incubated for 1 hour at ambient temperature to detect primary
117 antibodies. Nuclei were labelled by 5-minute incubation with DRAQ5 (Cell Signaling, 4084)
118 diluted 1:400 in blocking buffer. Confocal z-stacks spanning the entire embryo were collected
119 with 5 μm spacing on the Olympus FluoView FV1000 Confocal Laser Scanning Microscope
120 system with 20x UPlanFLN objective (0.5 NA) and 5x digital zoom.

121

122 **Image Analysis**

123 Image analysis was performed in ImageJ (imagej.net). Z-stacks from each embryo were
124 arranged into a montage and then each cell was manually assigned a TE or ICM identity based
125 on their position on the embryo surface (TE) or inside the embryo (ICM). Cells classified as ICM
126 were further manually scored as SOX17 positive or NANOG positive. Pyknotic nuclei, indicating
127 cell death, and mitotic nuclei were excluded from the analysis, and were less than 2% of all cells
128 considered for analysis.

129

130 **Statistical Analysis**

131 Unpaired two-tailed t-tests were performed in Graphpad Prism 8 for macOS
132 (www.graphpad.com).

146 **Figure Legend**

147

148 **Figure 1. BSA antagonizes signaling by exogenous FGF4**

149 A) Experimental design for embryos shown and analyzed in this figure. Red = NANOG

150 indicative of epiblast cell fate, green = SOX17 indicative of primitive endoderm cell fate.

151 B) Immunostaining for SOX17 to identify primitive endoderm (PE) cells and NANOG to identify

152 epiblast (EPI) cells in embryos cultured for 66 hours starting from 2-cell stage in KSOM with 1

153 mg/mL BSA or without BSA (Millipore-Sigma MR-121-D and MR-107-D, respectively), but with 1

154 mg/mL added PVA (Sigma 360627). n = number of embryos examined. p = Student's t-test. n.s.

155 = not significant ($p > 0.2$).

156 C) Quantification of the total inner cell mass (ICM) and trophectoderm (TE) cells in embryos

157 cultured in indicated conditions and proportion of ICM cells contributing to PE and EPI in these

158 embryos. Each symbol represents a single embryo, column = mean, and error bars = standard

159 deviations. p = Student's t-test. n.s. = not significant ($p > 0.2$).

160 D) Immunostaining for SOX17 and NANOG in embryos cultured in KSOM + 150 ng/mL FGF4

161 (R&D Systems 235-F4-025) and 1 μ g/mL Heparin (Sigma H3149) in the presence or absence of

162 1 mg/mL BSA. Each symbol represents a single embryo, column = mean, and error bars =

163 standard deviations. p = Student's t-test. n.s. = not significant ($p > 0.2$).

164 E) Quantification of lineage specification in embryos cultured in conditions indicated. Each

165 symbol represents a single embryo, column = mean, and error bars = standard deviations.

166 F) Response of embryos cultured in KSOM without 1 mg/mL BSA to low dose of exogenous
167 FGF4 and 1 µg/mL Heparin. Each symbol represents a single embryo, column = mean, and
168 error bars = standard deviations. p = Student's t-test.
