SUMMARY

The formation of appropriately patterned blood vessel networks requires endothelial cell migration and proliferation. Signaling through the Vascular Endothelial Growth Factor A (VEGFA) pathway is instrumental in coordinating these processes. mRNA splicing generates short (diffusible) and long (extracellular matrix bound) Vegfa isoforms. The differences between these isoforms in controlling cellular functions are not understood. In zebrafish, vegfaa generates short and long isoforms, while vegfab only generates long isoforms. We found that mutations in vegfaa affected endothelial cell migration and proliferation. Surprisingly, mutations in vegfab specifically reduced endothelial cell proliferation. Analysis of downstream signaling revealed no change in MAPK (ERK) activation, while inhibiting PI3 kinase signaling phenocopied vegfab mutants. The cell cycle inhibitor cdkn1a/p21 was upregulated in vegfab deficient embryos. Accordingly, reducing cdkn1a/p21 restored endothelial cell proliferation. Together, these results suggest that extracellular matrix bound Vegfa acts through PI3K signaling to specifically control endothelial cell proliferation during angiogenesis independently of MAPK (ERK) regulation.
INTRODUCTION

The vascular system supplies our bodies with oxygen and nutrients to ensure efficient tissue homeostasis. In order to fulfil these functions, appropriate numbers of blood vessels need to be generated in the embryo or maintained during adulthood (Adams and Alitalo, 2007; Dejana et al., 2017; Potente et al., 2011). The overproduction of blood vessels can lead to age-related macular degeneration (Mitchell et al., 2018), diabetic retinopathy (Wong et al., 2016) or cancer growth (Viallard and Larrivee, 2017). Formation of an insufficient number of blood vessels on the other hand can cause hypoxia, resulting in tissue damage as seen in atherosclerotic complication (Gimbrone and Garcia-Cardena, 2016).

Members of the vascular endothelial growth factor (VEGF) family are established regulators of vascular development (Alvarez-Aznar et al., 2017; Koch and Claesson-Welsh, 2012; Simons et al., 2016). For instance, the formation of new blood vessels from pre-exiting ones, termed angiogenesis, heavily relies on VEGFA and its receptor VEGFR2 (Kdr or Flk1). Accordingly, heterozygous Vegfa mutant mice die in utero with vascular defects (Carmeliet et al., 1996; Ferrara et al., 1996). Subsequent studies showed that VEGFA controls differentiation, sprouting, migration, proliferation and survival of endothelial cells (ECs). Despite the identification of several downstream players, such as Phosphoinositide 3-kinase (PI3K) (Graupera and Potente, 2013) and Mitogen-activated protein kinase (MAPK/ERK) (Simons et al., 2016), it is not known how VEGF signalling can differentially activate these pathways and how this activation might lead to the observed broad array of cellular outcomes. For example, the PI3K pathway controls EC survival in response to VEGFA in cultured cells (Gerber et al., 1998; Nakatsu et al., 2003), while in vivo studies in the developing mouse retina (Graupera et al., 2008) and in zebrafish embryos (Nicoli et al., 2012) suggested that PI3K signalling predominantly
regulates EC migration. More recent studies, however, also suggested a function of PI3K signalling in EC proliferation during retinal development (Angulo-Urarte et al., 2018; Ola et al., 2016) and in vascular malformations (Castel et al., 2016; Castillo et al., 2019; Castillo et al., 2016). Further work in mouse and in cell culture has shown that ERK signalling downstream of VEGFA stimulates EC proliferation (Koch and Claesson-Welsh, 2012), vessel integrity (Ricard et al., 2019) and artery formation (Simons and Eichmann, 2015). Another study in zebrafish embryos, however, implicated ERK signalling mainly in regulating EC migration, being dispensable for early artery differentiation (Shin et al., 2016). Therefore, we still lack an understanding of the sequence of downstream VEGF signalling events that occur during blood vessel formation. We also do not understand how these might be triggered in different EC populations through differential ERK and PI3K signalling.

One key aspect of VEGFA biology is the existence of differentially spliced isoforms (Bowler and Oltean, 2019). Longer isoforms bind heparin and are associated with the extracellular matrix (ECM), while the short, 121 amino acid (aa) isoform is diffusible (Vempati et al., 2014). Studies in mice have shown that these isoforms differentially affect blood vessel formation. Genetically engineered mice, which only express the VEGFA165 isoform are viable (Stalmans et al., 2002), while mice expressing only VEGFA121 show angiogenesis defects (Carmeliet et al., 1999; Ruhrberg et al., 2002; Stalmans et al., 2002). Thus, the ability to associate with the extracellular matrix might change VEGFA downstream signalling and/or gradient formation, as shown in cultured cells (Chen et al., 2010).

Zebrafish contain two vegfa paralogs, vegfaa and vegfab, likely being generated during a genome duplication event (Taylor et al., 2003; Taylor et al., 2001). Both genes are expressed during early embryogenesis and encode differentially spliced gene products, with vegfaa
encoding 121- and 165 aa isoforms (Gong et al., 2004; Liang et al., 1998), and vegfab encoding 171 and 210 aa isoforms (Bahary et al., 2007). Therefore, while vegfaa generates both diffusible and ECM bound isoforms, vegfab only generates ECM bound isoforms. Here, we have generated zebrafish mutants for vegfaa and vegfab. We find that, in agreement with studies in mice, vegfaa is haploinsufficient. By contrast, vegfab mutants showed only mild vascular defects and survived to adulthood. Surprisingly, however, EC proliferation was specifically affected in vegfab mutants. Using inhibitor treatments and time-lapse analysis of vascular development, we show that this phenotype was caused by impaired PI3K signalling without altering ERK activation. Further analysis of downstream targets identified the cell cycle regulator Cdkn1a/p21 as a PI3K target. Finally, we show that inhibition of PI3K signalling in the mouse retina similarly affected EC proliferation. Together, our studies support a model, in which activation of PI3K signalling downstream of ECM bound VEGFA is necessary to allow for optimal EC proliferation during angiogenesis that is independent of signalling through ERK.

RESULTS

Vegfaa and Vegfab mutants show distinct defects during brain blood vessel formation

In order to investigate the role of each of the zebrafish Vegfa homologues during angiogenesis, we generated zinc finger (for vegfaa) or TALEN (for vegfab) mutants, targeting the first exon of either gene. We recovered two frameshift mutations, leading to severely truncated proteins of 18 (vegfaamu128) or 12 amino acids (vegfabmu155), respectively (Figure 1A, B). To assess changes in vascular morphology, we crossed both mutant lines into the Tg(kdrl:EGFP)s843 background, expressing EGFP in ECs (Jin et al., 2005). We first focused our analysis on the developing hindbrain vasculature (Figure 1C), which relies on VEGFR2 signaling (Bussmann et al., 2011;
Fujita et al., 2011; Ulrich et al., 2011). The arterial pole of the hindbrain vasculature forms via two successive sprouting events emanating from the primordial hindbrain channels (PHBC), two laterally located veins (Bussmann et al., 2011; Fujita et al., 2011; Ulrich et al., 2011). The first sprouting event generates the medially located basilar artery (BA), while the second event subsequently generates central arteries (CtAs), which connect the PHBCs with the BA (Figure 1D-F; Video S1). Both vegfa genes show distinct expression domains in the brain, as shown by fluorescence in situ hybridization at 32 hpf. We detected expression of vegfaa dorsal to the PHBC at positions of forming CtAs (Figure S1A, arrows, B). For vegfab, expression was evident in the midline region, where the BA would form (Figure S1C, arrowheads, D) and dorsally of the PHBCs (Figure S1C, arrows, D).

In line with these gene expression data, we observed specific vascular defects in each mutant. Homozygous vegfaamu128 mutants showed a significant decrease in CtA numbers, while these were unaffected in vegfabmu155 mutants (Figure 1 G-L, quantified in Figure 1P; Videos S2 and S3). By contrast, the BA failed to form in these mutants, as previously reported (Rossi et al., 2016). Its formation was unaffected in vegfaamu128 mutants (Figure 1G-L). To analyse whether vegfab can contribute to CtA formation, we analysed vegfaamu128; vegfabmu155 double mutants. These showed a complete lack of BA and CtAs, while the PHBCs still formed (Figure 1M-O, quantified in Figure 1P). These results suggest that during brain blood vessel sprouting, vegfaa and vegfab have acquired specific regulatory elements that drive their expression in separate domains, thereby locally influencing blood vessel formation.
Mutant hindbrain phenotypes display cell number changes in particular blood vessels

Angiogenesis requires the coordination of endothelial cell migration and proliferation (Adams and Alitalo, 2007; Hogan and Schulte-Merker, 2017; Potente et al., 2011; Schuermann et al., 2014). We therefore set out to investigate the influence of either vegfa gene on these processes. To do so, we quantified cell numbers using the double transgenic line Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1a:nEGFP)y7, in which EC nuclei contain EGFP protein and membranes are labelled by virtue of mCherry expression (Hogan et al., 2009; Roman et al., 2002). After completion of BA and CtA sprouting (58 hpf time point), both mutants displayed lower total cell numbers when compared to wildtype (wt) embryos (Figure 1Q-T). Further analysis revealed that neither vegfaa mu128 nor vegfab mu155 affected PHBC cell numbers (Figure 1U). As expected, BA cell numbers were specifically affected in vegfab mu155 mutants (Figure 1V). The amounts of CtAs decreased about 50% in vegfaa mutants (Figure 1R, quantified in Figure 1P) and accordingly, total CtA cell numbers were also reduced in these mutants (Figure 1W). Surprisingly however, total CtA cell numbers were similarly decreased in vegfab mutants when compared to wt embryos (Figure 1W), even though vegfab mu155 mutants formed normal numbers of CtAs (Figure 1P). We therefore reasoned that vegfab might affect EC numbers in individual CtAs. Indeed, while individual CtAs in vegfaa mu128 mutants contained similar quantities of ECs compared to wt embryos, cell numbers per CtA in vegfab mu155 were significantly decreased (Figure 1X). Thus, vegfab specifically influenced EC numbers in blood vessel sprouts without affecting their growth. These findings suggest that the two zebrafish vegfa paralogs not only differentially affect blood vessel formation due to their distinct gene expression domains, but that they might also have acquired separate biological functions.
Vegfab signalling is specifically required for EC proliferation

To test this hypothesis, we leveraged the accessibility of zebrafish for time lapse imaging. We used $Tg(kdrl:Hsa.HRAS-mCherry)916; Tg(fli1a:nEGFP)7$ embryos to track the proliferative behaviours of individual ECs. In wt embryos, we observed CtA EC proliferation between 32 and 42 hpf (Figure S1E, white dots; Video S4). Ultimately, 16.5% of CtA cells were derived from a cell division (Figure S1H, I). Although fewer CtAs sprouted in vegfaamu128 mutants, the ones that formed displayed a similar percentage of CtA cells derived from proliferation when compared to wt embryos (Figure S1F, white dots, quantified in Figure S1H, I; Video S5). By contrast, vegfabmu155 mutants showed a reduction of cells derived from proliferation to 3.4% (Figure S1G, white dots, quantified in Figure S1H, I; Video S6). Thus, vegfaa signalling cannot compensate for loss of vegfab signalling in stimulating EC proliferation during CtA sprouting. Together, these findings suggest that vegfab signalling might be critically required in controlling EC proliferation.

VEGFab and VEGFaa differentially affect intersegmental blood vessel sprouting

To corroborate our findings, we analyzed the morphology of intersegmental blood vessels (ISVs), the first blood vessels that form via angiogenesis in zebrafish embryos (Isogai et al., 2003). In wt embryos, ISVs sprout from the dorsal aorta and anastomose in the dorsal region of the zebrafish trunk at 30 hpf (Isogai et al., 2003) (Figure S2A, B, quantified in Figure S2K). vegfaamu128 heterozygous embryos showed a variable degree of stalled ISVs (Figure S2C, D, arrowhead, quantified in Figure S2K), indicating haploinsufficiency, as previously reported for VEGFA mutant mice (Carmeliet et al., 1996). ISVs failed to form in vegfaamu128 homozygous embryos (Figure S2E, F, quantified in Figure S2K), as shown earlier for independently generated
vegfaa mutants (Rossi et al., 2016). Surprisingly, neither vegfab\textsubscript{mu155} heterozygous nor homozygous mutants showed defects in ISV morphology at 30 hpf (Figure S2G-J, quantified in Figure S2K). These results thus underscore a conserved role of vegfaa signaling during ISV formation, while vegfab appears to be dispensable during this process.

Motivated by our observations concerning the specific functions of vegfaa and vegfab in CtA formation, we set out to determine whether vegfab might similarly affect EC proliferation in ISV ECs. As previously reported, wt embryos contained either 3 or 4 cells per ISV (Figure 2A, B, quantified in Figure 2G), (Childs et al., 2002; Costa et al., 2016; Siekmann and Lawson, 2007). ISVs in heterozygous vegfaa\textsubscript{mu128} mutants contained significantly fewer endothelial cells (Figure 2C, D, quantified in Figure 2G). Vegfab\textsubscript{mu155} mutants displayed a reduction in ISV EC numbers (Figure 2E, F, quantified in Figure 2G) without obvious sprouting defects. Thus, similar to brain CtAs, loss of vegfab specifically reduces ISV cell numbers.

We then set out to analyze how vegfaa and vegfab might affect endothelial cell migration and proliferation. To do so, we performed time-lapse imaging of Tg\textit{(kdrl:Hsa.HRAS-mCherry)\textsubscript{s916}}; Tg\textit{(fli1a:nEGFP)\textsubscript{y7}} double transgenic zebrafish embryos. As determined by nuclear displacement, wt tip cells on average migrated about 100 μm within 6 h (Figure 2H, arrowheads, quantified in Figure 2L; Video S7), as previously reported (Costa et al., 2016). By contrast, ISVs in vegfaa\textsubscript{mu128} heterozygous fish displayed two different behaviors: Tip cells either migrated similar to wt cells (Figure 2I, quantified in Figure 2L; Video S8), or showed severe migration defects with tip cells stalling midway along the somite (Figure 2J, quantified in Figure 2L; Video S9). Therefore, lack of one vegfaa allele can differentially affect individual ISVs. Vegfab homozygous mutants showed a decrease in cell migration in the midway position, but later recovered and reached the dorsal region of the embryo at the same time as the wildtype cells did.
Therefore, absence of vegfaa signaling can have pronounced effects on EC migration, while vegfab mutants show only minor cell migration defects.

By contrast, EC proliferation was strongly affected in vegfaa and vegfab mutants. Time-lapse imaging revealed that in wt embryos each ISV showed around one EC proliferation event (Figure 2M, quantified in Figure 2P; Video S11). This was reduced to about half for both vegfaamu128 (Figure 2N, quantified in Figure 2P; Video S12) and vegfabmu155 (Figure 2O, quantified in Figure 2P; Video S13) mutants. To further investigate the influence of vegfab on EC proliferation, we globally overexpressed Vegfab via mRNA injection. This led to an increase in EC numbers within ISVs without affecting their overall morphology (Figure S3). In summary, our findings suggest that vegfaa signaling drives EC migration and proliferation, while vegfab signaling mainly affects EC proliferation.

**Vegfab controls EC proliferation independently of ERK signaling**

We reasoned that the observed differences in EC behaviors between vegfaamu128 and vegfabmu155 mutants might enable us to dissect out signaling pathways downstream of VEGFA that specifically control proliferation. Previous studies implicated signaling through MAPK/ERK in influencing EC proliferation (Claesson-Welsh, 2016; Simons et al., 2016). We therefore set out to determine potential changes in ERK phosphorylation in vegfab mutants. Surprisingly, pERK antibody staining in ISVs was unchanged in vegfab mutant embryos (Figure 3A, B, quantified in Figure 3C). ERK signaling furthermore influences gene expression patterns within ISVs (Shin et al., 2016). We did not detect changes in either of the two reported ERK downstream genes dll4 (Figure 3D-G) or flt4 (Figure 3H-K) in vegfabmu155 mutants. Lastly, treating wt embryos with...
phorbol 12-myristate 13-acetate (PMA), which increased ERK phosphorylation (Figure S4), did not change EC numbers within ISVs (Figure 3L-Q, quantified in Figure 3X). PMA treatment also failed to rescue EC numbers in vegfabmu155 mutants (Figure 3R-W, quantified in Figure 3X). Therefore, ERK signaling does not play a major role downstream of vegfab signaling in controlling EC proliferation in ISVs.

Loss of PI3K signaling specifically affects endothelial cell proliferation

We next focused on PI3K signaling, as another important pathway downstream of VEGFA signaling (Graupera and Potente, 2013). Treating zebrafish embryos with 10 um of the PI3K inhibitor LY294002 (Vlahos et al., 1994) reduced phosphorylation of the PI3K downstream kinase AKT without affecting gross embryonic morphology (Figure S5). ISV morphology was unaffected when treating zebrafish embryos from 22 to 32 hpf (Figure 4A, D). However, similar to vegfabmu155 mutants, EC numbers were significantly reduced in inhibitor treated embryos when compared to DMSO treated control embryos (Figure 4B, C, E, F, quantified in Figure 4G). We then investigated whether this reduction in cell numbers was due to the reported effects of PI3K signaling on cell migration. Surprisingly, time-lapse imaging of developing ISVs did not reveal changes in cell migration upon LY294002 treatment (Figure 4H, I, quantified in Figure 4J; Videos S14 and 15). We therefore investigated EC proliferation in inhibitor treated embryos. This analysis revealed that blocking PI3K signaling led to a decrease in proliferation events (Figure 4K, L, quantified in Figure 4M; Videos S16 and S17). As LY294002 inhibits multiple PI3K isoforms in addition to other kinases (Davies et al., 2000; Workman et al., 2010), we investigated ISV formation after treating embryos with the PI3K p110 alpha isoform specific inhibitor GDC-0326 (Heffron et al., 2016). GDC-0326 treatment effectively reduced AKT phosphorylation (Figure 4N, O, quantified in Figure 4P; Videos S18 and S19).
phosphorylation at concentrations ranging from 10 μM to 50 μM (Figure S6A) and reduced ISV cell numbers without affecting ISV morphology (Figure S6B-M, quantified in Figure S6N).

Thus, while not affecting ISV EC migration during short term inhibitor treatment, PI3K signaling downstream of the 110 alpha isoform plays important roles in controlling EC proliferation during developmental angiogenesis.

Cdkn1a/p21 is a downstream target of vegfab/PI3K signaling in regulating EC proliferation

To identify vegfab target genes that might lead to altered proliferative behaviors, we used Fluorescence-activated cell sorting (FACS) to sort GFP and mCherry positive ISV and arterial ECs from vegfab morpholino injected embryos using a triple transgenic strategy (Figure 5A). We then analyzed expression of genes implicated in cell cycle regulation. This analysis revealed mRNA upregulation of the negative cell cycle regulator cdkn1a/p21 in ECs of vegfab morpholino injected embryos (Figure 5B). We furthermore determined the influence of PI3K inhibition on Cdkn1a/p21 protein expression in cultured human umbilical vein endothelial cells (HUVEC). Overall Cdkn1a/p21 protein levels were unchanged after LY294002 treatment (Figure 5C). However, we detected a striking change in Cdkn1a/p21 protein localization from cytoplasmic towards nuclear (Figure 5D-I, quantified in Figure 5J). Nuclear localization has been implicated in mediating the cell growth inhibiting function of Cdkn1a/p21 (Zhou et al., 2001).

Thus, both vegfab and PI3K signaling can influence the abundance and localization of Cdkn1a/p21 in ECs.

Based on these findings, we investigated whether knocking down Cdkn1a/p21 could rescue the proliferation defects observed upon loss of vegfab or PI3K signaling. Injection of
Cdkn1a/p21 morpholino into wt embryos caused a mild increase in ISV EC numbers (Figure 6A, B, quantified in Figure 6E). Injecting Cdkn1a/p21 morpholinos into vegfabmu155 mutants led to a rescue of EC numbers back to wt levels (Figure 6C, D, quantified in Figure 6E). Similarly, injection of Cdkn1a/p21 morpholino prior to PI3K inhibitor treatment increased ISV EC numbers back to wt levels (Figure 6F-I, quantified in Figure 6J). Therefore, reducing Cdkn1a/p21 levels can rescue the proliferation defects observed upon loss of vegfab and PI3K signaling.

Inhibition of PI3 kinase signaling during retinal angiogenesis reduces endothelial cell proliferation

To investigate whether PI3K signaling influences EC proliferation in other angiogenic settings, we analyzed blood vessel development in the mouse retina. Here, new blood vessels sprout from the optic nerve towards the periphery of the retina after birth. Intraperitoneal injection of the PI3k 110 alpha subunit-specific inhibitor GDC-0941 effectively reduced AKT phosphorylation in ECs after 24 h of treatment, as analyzed in lung lysates from P6 mice (Figure S7A). It furthermore reduced the phosphorylation of S6 kinase, a downstream target of PI3K signaling (Chung et al., 1994) (Figure S7B-E). Incorporation of EdU was strongly reduced in inhibitor treated embryos, both at the angiogenic front (Figure 7A-D, quantified in G) and in the vein region of the retina (Figure 7E, F, quantified in H), where ECs continue to proliferate. Thus, similar to our observations in zebrafish embryos, PI3K signaling affects endothelial cell proliferation during mouse retinal angiogenesis.
1 DISCUSSION

Tissue vascularization requires coordinated cellular responses to growth factors, such as Vegfa, in order to generate appropriate amounts of new ECs, allow them to sprout into avascular areas and ultimately differentiate into the correct numbers of arteries, capillaries and veins. How a single ligand can control the multitude of cellular responses necessary to achieve these tasks is an outstanding question in the field. Our work on the duplicated Vegfa ligands in zebrafish identifies a specific function of PI3 kinase signaling in response to ECM bound vegfab ligands in regulating EC proliferation. This was an unexpected discovery, since signaling through MAPK/ERK was thought to be the main driver of EC proliferation downstream of Vegfa signaling (Koch and Claesson-Welsh, 2012; Meadows et al., 2001; Simons et al., 2016; Srinivasan et al., 2009; Takahashi et al., 1999). What might be the reason for this discrepancy?

So far, animal models carrying mutations in components of the Vegf pathway showed simultaneous defects in EC proliferation and migration. For instance, zebrafish mutants in kdrl, plcg or treated with the Vegf pathway inhibitor SU5416 display an absence of ERK phosphorylation (Fish et al., 2017; Shin et al., 2016), together with a reduction in ISV outgrowth and cell numbers. Similarly, mutants in vegfaa show a severe reduction in EC numbers and migration during ISV formation (Jin et al., 2017), phenotypes also seen in VEGFA mutant mice (Carmeliet et al., 1996; Ferrara et al., 1996). Therefore, it has been difficult in animal models to dissect out the individual contribution of a given gene or its downstream pathway components to either process.

Specific manipulations of ERK signaling in cultured ECs showed a requirement for DNA synthesis downstream of VEGFR2 activation, a process that was independent of PI3K activity (Takahashi et al., 1999). However, deletion of ERK1 in mice did not result in vascular
phenotypes (Pages et al., 1999), while knocking out ERK2 specifically in ECs in an ERK1−/− background affected EC migration and proliferation (Srinivasan et al., 2009). Our study together with the study of Shin et al. (Shin et al., 2016) suggests that in developing ISVs, ERK signaling rather controls EC migration instead of proliferation. A similar specific influence of ERK signaling on migration was reported in a HUVEC tube formation assay and for tumor ECs (Mavria et al., 2006). These results suggest that ERK phosphorylation can influence EC migration and/or proliferation depending on the developmental setting and the EC type analyzed.

Our work points towards a critical role of PI3K signaling for EC proliferation during ISV outgrowth. We find that blocking PI3K using different inhibitors selectively prevented ISV EC proliferation without influencing cell migration. This is in contrast to previous studies showing that PI3K signaling specifically affected EC migration in developing mouse embryos and in cultured ECs, with only minor effects on EC proliferation (Graupera et al., 2008; Takahashi et al., 1999). A previous study in zebrafish ISVs also showed that blocking PI3K signaling using the LY294002 inhibitor affected cell migration without reducing EC proliferation (Nicoli et al., 2012). We directly imaged dividing cells using time-lapse imaging, while Nicoli et al. determined differences in BrdU incorporation. It might therefore be that PI3K signaling is important for cytokinesis with less effects on DNA synthesis, as previously shown in Dictyostelium discoideum cells (Janetopoulos et al., 2005). In addition, differences in the duration of PI3K inhibition will affect EC behaviors. We blocked PI3K signaling for 10 hours, while Graupera et al. analyzed vascular phenotypes after several days of removing PI3K 110alpha kinase function from ECs (Graupera et al., 2008).

Other studies have shown that PI3K signaling downstream of VEGF receptor signaling can lead to an increase in EC proliferation. Dayanir et al. generated a chimeric VEGF receptor 2...
that could be activated using CSF-1 (Dayanir et al., 2001). When PI3K signaling was compromised, CSF-1 stimulation of this receptor failed to induce EC proliferation. Another study showed that Y1212 in VEGFR2 was important to control PI3K signaling pathway activation upstream of myc-dependent EC proliferation (Testini et al., 2019). In line with our observations in the mouse retina, blocking PI3K signaling in this setting reduced the number of phospho-histone 3 positive ECs (Ola et al., 2016) and led to a reduction in EdU incorporation (Angulo-Urarte et al., 2018). Importantly, activating mutations in PIK3CA can lead to venous malformations that are characterized by increased EC proliferation (Castel et al., 2016; Castillo et al., 2019; Castillo et al., 2016). Together, these studies suggest a more important role of PI3K signaling in controlling EC proliferation downstream of Vegf signaling than previously anticipated. However, further work will be necessary to precisely determine in which EC populations and at which stages of the cell cycle PI3K signaling is required. Of note, we still observed EC proliferation in PI3K inhibitor treated or vegfab mutant embryos, suggesting the existence of other signaling pathways contributing to ISV EC proliferation.

Why are Vegfab ligands specifically affecting PI3K signaling and EC proliferation without a major influence on EC migration? One reason for this might due to the existence of differentially spliced Vegfa isoforms. In other species, all Vegfa isoforms are being generated by the same gene, while in zebrafish only vegfaa can generate both short and long, ECM binding, isoforms (Bahary et al., 2007). Vegfab exclusively generates ECM binding isoforms. This setting allowed us to determine the unique effects of ECM binding Vegfa isoforms on EC behaviors during embryogenesis. Previous studies in developing mice (Ruhrberg et al., 2002; Stalmans et al., 2002), disease settings (Brash et al., 2019; Cheng et al., 1997; Guo et al., 2001; Kazemi et al., 2016) and in cultured ECs (Chen et al., 2010; Delcombel et al., 2013; Fearnley et al., 2016;
Herve et al., 2005; Park et al., 1993; Shiying et al., 2017) carefully investigated the effects of the different VEGF isoforms on cellular behaviors (for review see (Peach et al., 2018; Woolard et al., 2009)). Some studies suggested that there are no differences in the ability of various VEGFA isoforms to support EC proliferation (Ruhrberg et al., 2002), while others showed that ECs cultured on ECM derived from cells expressing VEGF189 or VEGF206 proliferated more strongly than those cultured in the presence of VEGF165 (Park et al., 1993). Our studies support the latter findings by showing that matrix bound Vegfα isoforms stimulate EC proliferation. We furthermore find that EC proliferation in vegfα mu155 mutants is more strongly affected in actively sprouting ECs in the forming CtAs and ISVs. We hypothesize that this might be due to the fact that during angiogenic growth ECs degrade the ECM, possibly releasing bound VEGF molecules, which would make them available to the invading ECs. Thus, the ability of long VEGF isoforms to associate with the ECM could provide a readily available growth factor pool within tissues.

Cell cycle regulation is a key prerequisite for proper embryonic development and tissue homeostasis and is regulated by a stoichiometric competition between proliferation promoting cyclinD expression that is induced by mitogens and inhibitory cdkn1a/p21 (Pack et al., 2019). Previous work showed that cdkn1a/p21 levels vary between cells in a given population and that these levels can determine the proportion of cells that actively cycle (Overton et al., 2014). Furthermore, increased levels of cdkn1a/p21 after mitosis can lead to cellular quiescence, while cells with lower cdkn1a/p21 levels continue to proliferate (Spencer et al., 2013). A similar balance of cdkn1a/p21 might control the number of proliferating ECs during ISV sprouting. Indeed, when comparing different ISVs, we observe a variation in proliferating ECs. In cdkn1a/p21 knockdown embryos, a greater number of ECs proliferate, while a reduction in
vegfab signaling increases expression of cdkn1a/p21 and causes fewer ECs to proliferate. Recently, increases in ERK signaling were shown to upregulate cdkn1a/p21 expression in ECs in the mouse retina, resulting in cell cycle arrest (Pontes-Quero et al., 2019). Our results suggest that PI3K signaling downstream of vegfab similarly controls the amount and/or localization of cdkn1a/p21, thereby determining the amount of actively cycling ECs during angiogenesis. Of note, cdkn1a/p21 can also influence cell migration via the inhibition of Rho/ROCK (Rho-associated kinase) signaling (Kreis et al., 2019; Tanaka et al., 2002). During tumorigenesis, upregulation of cdkn1a/p21 can induce growth arrest, allowing breast cancer cells to become more migratory and invasive (Qian et al., 2013). Previous studies showed that activation of the PI3K target Akt results in cdkn1a/p21 cytoplasmic localization, releasing cdkn1a/p21’s growth inhibiting function (Zhou et al., 2001). Our results show a similar effect of PI3K signaling on cdkn1a/p21 localization in ECs. Therefore, proper activation of PI3K signaling upstream of cdkn1a/p21 might be important for controlling the switch between EC migration and proliferation. A better understanding of the mechanisms controlling this switch will further our understanding of tissue morphogenesis and help to manipulate aberrant blood vessel development in beneficial ways.

MATERIALS AND METHODS

Zebrafish strains
Zebrafish were maintained as described previously (Westerfield, 1993). Transgenic lines and mutants used were Tg(kdrl:EGFP)s843, Tg(kdrl:Hsa.HRAS-mCherry)s916, Tg(fli1a:nEGFP)y7, Tg(dll4:gal4)mu106, Tg(UAS:GFP)nkuasgfp1a, vegfaamu128 (this study), vegfabmu155 (this study).

References for zebrafish transgenic lines can be obtained on zfin.org. Adult zebrafish used in this
study to generate embryos were between 1-2 years of age. Embryos were not selected for gender. All animal experiments were performed in compliance with the relevant laws and institutional guidelines and were approved by local animal ethics committees of the Landesamt für Natur, Umwelt und Verbraucherschutz Nordrhein-Westfalen.

Morpholino injections and drug treatment

Morpholinos were obtained from Gene-Tools and dissolved in distilled water. Morpholinos (MOs) targeting cdkn1a/p21 (3 ng/embryo) (Sidi et al., 2008), vegfab (5 ng/embryo) (Bahary et al., 2007) and a standard control MO (Hasan et al., 2017) have been described previously. To inhibit PI3K, embryos were dechorionated and incubated in 10 uM LY-294002 hydrochloride (SIGMA) for 10 hours prior to imaging. To specifically inhibit PI3K 110 alpha, embryos were dechorionated and incubated in 10 uM, 25 uM or 50 uM of GDC-0326 (Cayman Chemical). To activate ERK signalling, embryos were dechorionated and incubated in 0.25 uM Phorbol-12-myristat-13-acetate (PMA) (SIGMA) for 4 hours prior to imaging.

Live imaging, confocal microscopy and image processing

For in vivo imaging, live embryos were mounted in 1 % or 1.5 % low-melting-point agarose in E3 embryo medium with 168 mg l-1 tricaine (1x) for anaesthesia and 0.003 % phenylthiourea to inhibit pigmentation. Imaging was carried out on an inverted Leica SP5, SP8 or a Zeiss LSM780 confocal microscope using a 20× dry objective. A heated microscope chamber at 28.5 °C was used for recording time-lapse videos. Stacks were taken every 15-20 min with a step size of 2 um. Confocal stacks and time-lapse videos were analysed using IMARIS Software (Bitplane).
Fluorescence-activated cell sorting (FACS) of arterial ECs from zebrafish embryos

Arterial ECs were obtained from triple-transgenic zebrafish embryos, in which

*Tg(kdrl:Hsa.HRAS-mCherry)*<sub>916</sub> exhibits pan-endothelial expression, and the combination of

*Tg(dll4:gal4)*<sub>mu106; (UAS:GFP)*<sub>nkuasgfp1a</sub> labels arterial ECs within this population. Embryos were
deyolked in calcium free Ringer’s solution and treated with 0.5% Trypsin-EDTA (Gibco, 15400-054) containing 50 mg/ml collagenase Type IV (Gibco,17104-019) and dissociated by constant
pipetting. The reaction was stopped by adding 5% FBS and the cells were pelleted by
centrifugation. The pelleted cells were washed with 1x HBSS buffer (Gibco, 14185052) and
passed through 40-micron nylon filters. FACS was performed on the cell suspension for arterial
(mCherry+/GFP+) and the venous (mCherry+) cells at room temperature. Sorted cells were
collected in RLT buffer (Qiagen) for RNA isolation.

Quantitative Polymerase Chain Reaction (qPCR)

RNA was isolated with RNeasy Plus Micro kit (Qiagen) from whole zebrafish embryos or sorted
cells and reverse transcribed with iScript cDNA Synthesis Kit (BioRad). For qPCR, cDNA
produced from 15 ng RNA and 8 pmol of each forward and reverse primer per reaction and
Power SYBR Green PCR Master Mix (Applied Biosystems) were used. Relative expression was
quantified by ΔΔCt method using RPL13A as an endogenous control. The expression in control
sample (unsorted cells/ctr MO injected embryos) was set as 1. ΔCt values were used for
statistical analysis. The following primers were used:

Cdk2-fwd: 5’ -CGGAGGGCACTGTTTCTGGAG- 3’
Cdk2-rev: 5’ -ACATTTGCCCAAGAAGGTCTCTGCC- 3’
Cdkn1a/p21-fwd: 5’ -AGCTTCAGGTGTTCCTCAGCTCCT- 3’
Generation of \textit{vegfaa}_{mu128} and \textit{vegfab}_{mu155} mutant zebrafish

Zinc-finger nucleases (ZFNs) against \textit{vegfaa} were designed as previously described (Siekmann et al., 2009). In the \textit{vegfaa}_{mu128} allele, 7 nucleotides were deleted in exon 1 at the ZFN target site, resulting in an early stop codon after 18 amino acids. TALEN mutagenesis targeting \textit{vegfab} was performed as described previously (Sugden et al., 2017). In the \textit{vegfab}_{mu155} allele, 1 nucleotide was deleted and 2 nucleotides were inserted in exon 1 at the TALEN target site. This resulted in an early stop codon after 12 amino acids.

Genotyping

Primers for genotyping \textit{vegfaa} were:

\begin{verbatim}
Vegfaa-fwd: 5’ -GCTTTCTTAATTGTTTTGAGAGCCAG- 3’
Vegfaa-rev: 5’ --GGTGTGGGCTATTGCATTTC- 3’
\end{verbatim}

PCR products were digested with BccI (NEB). Fragment sizes are 116 bp + 123 bp for wild type allele and 239 bp for \textit{vegfaa}_{mu128} allele.

Primers for genotyping \textit{vegfab} were:

\begin{verbatim}
Vegfab-fwd: 5’ -GGACCAACATGGGATTCTTG- 3’
Vegfab-rev: 5’ -GGGTGGTCAGATATGCTCGT- 3’
\end{verbatim}
PCR products were digested with BsrI (NEB). Fragment sizes are 188 bp + 221 bp for wild type allele and 409 bp for vegfabmu155 allele.

**Cloning of vegfab171 and overexpression studies**

*Vegfab171* was amplified with primers

VEGFabattB1 ggggacaagttgtacaaaaaagcaggctGTAAAAACGGGCAACGGCGG and

VEGFab attB2 ggggaccactttgtacaagaaagctgggtTCACCTCCTTGGTTTGTCACATCTGC from zebrafish 24 hpf cDNA. cDNA was generated using RNA that was isolated with RNeasy Plus Micro kit (Qiagen) from whole zebrafish embryos and reverse transcribed with iScript cDNA Synthesis Kit (BioRad). BP reaction was performed according to the manufacturer’s instructions (ThermoFisher). Clones were verified by sequencing. *Vegfab* was then transferred into pCSDest (Villefranc et al., 2007) using LR cloning (ThermoFisher). Plasmid DNA was digested using NotI (NEB) and mRNA was generated using mMessage machine in vitro transcription kit (ThermoFisher). 50 pg of mRNA was injected into 1-cell stage zebrafish embryos.

**In situ hybridization and fluorescence in situ hybridizations (FISH) with antibody staining**

Whole-mount in situ hybridization was performed as previously described (Thisse and Thisse, 2008). Whole mount FISH combined with EGFP antibody staining was performed in *Tg(kdrl:EGFP)s843* line as described previously (Kochhan and Siekmann, 2013). Previously described probes were for *vegfaa* (Lawson et al., 2002), *vegfab* (Bahary et al., 2007), *dll4* (Siekmann and Lawson, 2007), *flt4* (Lawson et al., 2001).
Western blotting of zebrafish proteins

Dechorionated zebrafish embryos were de-yolked in Ginzburg buffer (55 mM NaCl, 1.8 mM KCl, 1.25 mM NaHCO₃) and lysed in Laemli buffer (20 embryos in 80 μl). Either 10 or 20 μl of sample were separated by 12 % SDS-PAGE and transferred onto PVDF membrane (Millipore). After blocking with 5 % Milk powder (Roth) in TBST, membranes were incubated with anti-phospho-p44/42 MAPK (Thr202/Tyr204) (1:1000; #8544; Cell Signaling), anti-p44/42 MAPK antibody (1:2000; #9102, Cell Signaling) and anti-αActin antibody (1:5000; A-5060, Sigma), Phospho-Akt (Ser473) (1:2000; #4060; Cell Signaling), Akt (1:1000; #9272; Cell Signaling). Primary antibodies were detected using mouse IgG HRP linked whole Ab (1:4000; NXA931; GE healthcare).

Immunostaining of zebrafish embryos

Immunostaining for phospho-p44/42 MAPK was performed as described previously (Costa et al., 2016).

Mouse retina

To inhibit PI3K signaling, Pictilisib (GDC-0941, Selleckchem) stock solution was prepared by dissolving 8.5 mg of powder in 63 ul DMSO. Before injection, 10 ul of the stock solution was diluted in 190 ul of corn oil to get a final concentration of 6.8 μg/ul. 25 ul of this solution (or vehicle only) was injected IP into each pup at P5 (55 mg/kg) and again 16 h later, before collecting the tissues at P6 (injections at -24 h and -8 h time points). To detect proliferating cells actively synthesizing DNA, EdU (Invitrogen - A10044) was injected IP 4 h before sacrifice; the signal was developed with the Click-it EdU Alexa Fluor 647 Imaging Kit.
**Immunohistochemistry of mouse retinae**

For mouse retina immunostaining, eyes were collected at the indicated time points and fixed in 4% PFA in PBS for 1h at room temperature (RT). After two PBS washes, retinas were micro-dissected and stained as described previously (Pontes-Quero et al., 2019). Briefly, retinas were blocked and permeabilized with 0.3% Triton X-100, 3% FBS and 3% donkey serum in PBS. Samples were then washed twice in PBLEC buffer (1 mM CaCl₂, 1 mM MgCl₂, 1 mM MnCl₂ and 1% Triton X-100 in PBS). Biotinylated isolectinB4 (Vector Labs, B-1205, diluted 1:50) or primary antibodies (see below) were diluted in PBLEC buffer and tissues were incubated in this solution for 2 h at RT or overnight at 4°C. After five washes in blocking solution diluted 1:2, samples were incubated for 1 h at RT with Alexa-conjugated secondary antibodies (Molecular Probes). After two washes in PBS, retinas were mounted with Fluoromount-G (SouthernBiotech). To detect EdU-labelled DNA, an additional step was performed before mounting using the Click-It EdU kit (Thermo Fisher, C10340). Primary antibodies were used against the following proteins: Erg (AF-647, Abcam ab196149, 1:100), Phospho-S6 Ribosomal Protein (Ser235/236) (Cell Signalling Ab #4856, 1:100). The following secondary antibodies were used: Donkey anti-rabbit Cy3 (1:400, 711-167-003, Jackson Immunoresearch) and Streptavidin Alexa 405 (1:400, S-32351, Thermofisher).

**Western blot analysis of mouse proteins**

For the analysis of protein expression, dissected organs were transferred to a reagent tube and frozen in liquid nitrogen. On the day of the immunoblotting the tissue was lysed with lysis buffer [(Tris-HCl pH=8 20 mM, EDTA 1 mM, DTT 1 mM, Triton X-100 1% and NaCl 150 mM, containing protease inhibitors (P-8340 Sigma) and phosphatase inhibitors (Calbiochem 524629)]
and orthovanadate-Na 1 mM) and homogenized with a cylindrical glass pestle. Tissue/cell
debri was removed by centrifugation, and the supernatant was diluted in loading buffer and
analyzed by SDS–PAGE and immunoblotting. Membranes were blocked with BSA and
incubated with primary antibodies diluted 1/1000 against Cdh5/VE-cadherin (BD Biosciences
555289), Phospho-Akt (Cell Signalling, #4060S), Akt (Cell Signaling #9272S) or β-Actin
(Santa Cruz Biotechnologies, sc-47778).

Microscopy of mouse retina

We used a Leica TCS SP8 confocal with a 405 nm laser and a white laser that allows excitation
at any wavelength from 470nm to 670nm. All images shown are representative of the results
obtained for each group and experiment. Littermates were dissected and processed under exactly
the same conditions. Comparisons of phenotypes or signal intensity were made with pictures
obtained using the same laser excitation and confocal scanner detection settings. Images were
processed using ImageJ/Fiji and Adobe Photoshop.

Quantitative analysis of retinal vasculature

Single low magnification (10x lens) confocal fields of immunostained retinas were quantified
with Fiji/ImageJ. Each microscopy field contained hundreds of ECs, and the relative or absolute
number of cells in each field is indicated in the charts by a dot. As indicated in figure legends,
microscopy images from several animals and retinas were used for the phenotypic comparisons
and quantifications. Vascular IsolectinB4+ area and Erg+ or Edu+ cells were quantified
semiautomatically using custom Fiji macros. Endothelial cell density (EC number/mm²) was
measured as the number of Erg+ cells relative to the vascularized IsolectinB4+ area in each field.
The frequencies of Erg+ cells (ECs) in S-phase (EdU+) was determined as the ratio of double-positive cells to the total number of Erg+ cells per field.

Statistical analysis

Two groups of samples with a Gaussian distribution were compared by unpaired two-tailed Student t-test. Comparisons among more than two groups were made by ANOVA followed by the Turkey pairwise comparison. Column statistics were performed on data sets to check for normal distribution and appropriate tests to determine significance were performed using the Prism7 software. Each experiment was performed at least three times. Graphs represent mean +/- SD as indicated, and differences were considered significant at p < 0.05. All calculations were done in Excel and final datapoints analyzed and represented with GraphPad Prism. The sample size was chosen according to the observed statistical variation and published protocols. The experiments were not randomized, investigators were not blinded to allocation during experiments and outcome assessment and sample sizes were not predetermined.

MATERIALS AVAILABILITY

All reagents and zebrafish lines generated in this study are available from the Lead Contact with a completed Materials Transfer Agreement.

ACKNOWLEDGEMENTS

We would like to thank Reinhild Bussmann, Mona Finch Stephen, Nadine Greer and Bill Vought for excellent fish care. In addition, we would like to thank Roman Tsaryk and Zeenat Diwan for critically reading of the manuscript. We are grateful to Federica Lunella for help with the mouse.
retina dissection and immunohistochemistry. This work was funded by the Max-Planck-Society (A.F.S.), the Deutsche Forschungsgemeinschaft (DFG SI-1374/4-1, DFG SI-1374/5-1 and DFG SI-1374/6-1; A.F.S.) and start-up funds from the Cardiovascular Institute of the University of Pennsylvania Perelman School of Medicine (A.F.S.). AUTHOR CONTRIBUTIONS

M.L. and A.F.S. conceived the experiments and analyzed the data. A.F.S. supervised the work. M.L. analyzed vegfaa and vegfab mutants, performed drug treatments, pERK stainings and p21 knockdown experiments. M.L. also performed all cell culture experiments. A.F.S. cloned vegfab and performed overexpression experiments. N.O. generated the vegfaa and vegfab mutants. E.L. performed FACS of zebrafish endothelial cells and qPCR experiments. D.H. analyzed data. S.F.R. performed mouse retina experiments and analyzed data. R.B. analyzed data of mouse retina. All authors discussed experiments and commented on the manuscript.

FIGURE LEGENDS

Figure 1. Mutations in vegfaa and vegfab affect hindbrain blood vessel formation

(A-B) Schematic presentation of zinc finger nuclease or TALEN target site at the genomic sequence for vegfaa (A) and vegfab (B). Black boxes in the gene structure represent exons and dashed lines represent introns, yellow triangle indicates the position of the targeting sites. Protein domains are displayed below in comparison with wild type protein. Black boxes represent sequences that are not annotated, red boxes are cystine-knot cytokine domains and yellow boxes are heparin binding domains.

(C) Cartoon of 58 hpf embryo, arrow indicates imaged region. (D-N) Maximum intensity projection of confocal z-stacks of Tg(kdrl:EGFP)s843 wild type (D), vegfaa mu128 (G), vegfab mu155 (J) and double mutant (M) embryos. Smaller rectangular panels (E, H, K and N) show cropped ventral region of the maximum intensity projection for better visualization of the basilar artery (BA). Dorsal views, anterior to the left. Scale bar = 100 um.

(F, I, L, O) Graphical representation of hindbrain vascular phenotypes, indicating the position of Primordial hindbrain channel (PHBC)-Central artery (CtA) connections (red filled circles), CtA-CtA connections (black dots) and CtA-BA-Posterior Communicating segments (PCS) connections (yellow filled circles).

(P) Quantification of CtA number in wild type (n = 10), vegfaa mu128 (n = 10), vegfab mu155 (n = 10) and double mutant embryos (n = 10). Values are mean±s.d.; n.s = not significant; **** p<0.0001.
(Q-S) Maximum intensity projections of confocal z-stacks of Tg(kdrl:Hsa.HRAS-
mCherry)s916; (fl1a:nEGFP)y7 wt (Q), vegfaa{	extsubscript{mu128}} (R) and vegfab{	extsubscript{mu155}} embryos (S).

Dorsal view, anterior to the left. Scale bar = 100 um.

(T-X) Quantification of the total cell numbers (T) as well as in the PHBC (U), BA (V) CtAs (W) and cells per CtA (X), for wt embryos (n = 6) compared to vegfaa{	extsubscript{mu128}} (n = 6) and vegfab{	extsubscript{mu155}} (n = 5) mutants. Dots represent individual embryos; black lines indicate the mean value±s.d.; n.s = not significant; ** p>0.0022; *** p>0.0003; **** p<0.0001.

Figure 2. Analysis of endothelial cell migration and proliferation in the trunk vasculature of vegfaa{	extsubscript{mu128}} and vegfab{	extsubscript{mu155}} mutants

(A-F) Maximum intensity projections of confocal z-stacks of Tg(kdrl:Hsa.HRAS-
mCherry)s916; (fl1a:nEGFP)y7 wt (A-B), heterozygous vegfaa{	extsubscript{mu128}} (C-D) and vegfab{	extsubscript{mu155}} (E-F) embryos; lateral view, anterior to the left. Scale bar = 100 um.

(G) Quantification of endothelial cell numbers per intersegmental blood vessel sprout (ISV) in wt (n = 12), heterozygous vegfaa{	extsubscript{mu128}} (n = 26) and vegfab{	extsubscript{mu155}} (n = 14) mutants at 32 hpf. Dots represent individual embryos; black lines indicate the mean value ±s.d.; **** p<0.0001.

(H-K) Confocal time-lapse images of individual sprouting ISV showing tip cell migration (arrowheads) in wt (H), heterozygous vegfaa{	extsubscript{mu128}} (I), severely affected heterozygous vegfaa{	extsubscript{mu128}} (J) and homozygous vegfab{	extsubscript{mu155}} (K) embryos; lateral view, anterior to the left. Scale bar = 20 um.

(L) Quantification of tip cell migration, measuring the dorsal movement of cell nuclei for wild type (grey; n = 13 ISVs, 4 embryos), vegfaa{	extsubscript{mu128+/-}} (blue; n = 11 ISVs, 4 embryos),
vegfaa

mu128 +/- severe (yellow; n = 11 ISVs, 4 embryos) and vegfabmu155 -/- (red; n = 11 ISVs, 4 embryos). Values are mean±s.d.

(M-O) Confocal time-lapse images of 10 growing ISVs in wild type (M), vegfaa

mu128+/- (N) and vegfabmu155 -/- (O) embryos (n=4 each) that were analyzed for cell proliferation. Arrowheads indicate cells derived from proliferation. Lateral views, anterior to the left.

Scale bar = 100 um.

(P) Quantification of proliferation events per ISV during 10 h of time lapse imaging from 22 - 32 hpf in wild type (n = 40 ISVs, 4 embryos), vegfaa

mu128+/- (n = 40 ISVs, 4 embryos) and vegfabmu155 -/- (n = 50 ISVs, 5 embryos). Dots represent individual embryos; black lines indicate the mean value ±s.d.; ** p>0.0022.

Figure 3. Vegfab is not essential for ERK phosphorylation or dll4 and flt4 expression in sprouting ISVs

(A-B) High magnification of confocal z-stack of anti-pERK antibody staining on transgenic Tg(fli:nEGFP)y7 embryos with quantitative heat map of pERK staining at 28 hpf for wt (A) and vegfabmu155 (B) embryos, lateral view, anterior to the left. Scale bar = 20 um.

(C) Quantification of pERK staining intensity of every ISV cell represented in relative units (R.U.) for wt (n = 5) and vegfabmu155 (n = 8) at 28 hpf. Dots represent individual embryos; black lines indicate the mean value±s.d. n.s = not significant.

(D-K) Whole mount in situ hybridization for dll4 (D-G) and flt4 (H-K) on wt (D-E and H-I)) and vegfabmu155 (F-G and J-K) embryos at 23 or 28 hpf. Lateral views, anterior to the left. Scale bar = 100 um.
(L-Q) Maximum intensity projections of Tg(kdrl:HsHRAS-mCherry)s916; (fli1a:nEGFP)y7 embryos treated with DMSO (L-N; n=13) or with 0.25 um PMA (O-Q; n=10).

(R-W) Maximum intensity projections of Tg(kdrl:HsaHRASmCherry)s916; (fli1a:nEGFP)y7 vegfabmu155 mutant embryos treated with DMSO (R-T; n=11) or vegfabmu155 mutant embryos treated with PMA (U-W; n=10). Lateral views, anterior to the left. Scale bar = 100 um.

(X) Quantification of endothelial cell numbers. Dots represent individual embryos; black lines indicate the mean value±s.d.; **** p<0.0001. Scale bar=100 um.

Figure 4. LY294002 mediated inhibition of PI3K affects endothelial cell proliferation

(A-F) Maximum intensity projection of a confocal z-stack of the trunk vasculature of double transgenic Tg(kdrl:Hsa.HRAS-mCherry)s916; (fli1a:nEGFP)y7 wt embryos treated with DMSO (A-C) or 10 uM LY294002 (D-F) at 32 hpf. Lateral views, anterior to the left. Scale bar = 100 um.

(G) Quantification of the cells per ISV in DMSO treated embryos (n = 24) compared to LY294002 treated embryos(n = 25). Dots represent individual embryos; black lines indicate the mean value ±s.d. **** p<0.0001.

(H, I) Confocal time-lapse images of individual sprouting ISV showing tip cell migration (arrowheads) in wt embryos treated with DMSO (H) or LY294002 (I) starting from 22 hpf for 6 h. Scale bar = 20 um.
(J) Quantification of tip cell migration, measuring the dorsal movement of cell nuclei for wild type embryos treated with DMSO (grey; 11 ISVs, 3 embryos) or LY294002 (blue; 11 ISVs, 4 embryos); Values are mean±s.d.

(K, L) Confocal time-lapse images of 10 growing ISVs in embryos treated with DMSO (K) or with LY294002 (L) that were analyzed for cell proliferation. Arrowheads indicate cells derived from proliferation. Scale bar = 100 μm.

(M) Quantification of proliferation events in ISVs during 10 h of time lapse imaging from 22 - 32 hpf after DMSO (n = 30 ISVs, 3 embryos) or LY294002 (n = 40 ISVs, 4 embryos) treatment. Dots represent individual embryos; black lines indicate the mean value±s.d.; ** p>0.0022.

Figure 5. Vegfab / PI3K signaling influences Cdkn1a/p21 expression and localization

(A) Cartoon depicting experimental set up for FACS and qPCR experiment. Triple transgenic embryos Tg(kdrl:Hsa.HRAS-mCherry)s916; (dll4:gal4)m106; (UAS:gfp)nkusagfp1a were injected with vegfab or control morpholino at the 1 cell stage and raised to 28 hpf. Embryos were dissociated and GFP/mCherry positive cells were FACS sorted.

(B) Expression of cell cycle regulators cdk2, cdkn1a/p21 and cdkn1b/p27 comparing cells from vegfab morpholino injected embryos with control morpholino injected embryos, which were set as 1 (n = 3 independent experiments). Expression data are shown as fold change; dots represent individual experiments; black lines indicate the mean value±s.d.; ** p>0.0022.
(C) Western Blot of proteins from Human Umbilical Vein Endothelial Cells showing decrease in AKT phosphorylation, while no change in Cdkn1a/p21 protein amount following LY294002 treatment was detected. Representative blot of n=3 is shown.

(D-I) Confocal images of Human Umbilical Vein Endothelial Cells treated with DMSO (D-F) or LY294002 (G-I). HOECHST staining labels nuclei, Cdkn1a/p21 protein in red, scale bar is 200 um.

(J) Quantification of nuclear fluorescence of Cdkn1a/p21 protein in DMSO (n=6 experiments) or LY294002 (n=6 experiments) treated Human Umbilical Vein Endothelial Cells in relative units (R.U.). Dots represent individual experiments; black lines indicate the mean value±s.d.; ** p>0.0022.

Figure 6. Cdkn1a/p21 knock down in zebrafish embryos rescues proliferation defects resulting from vegfab deficiency or PI3K inhibition

(A-D) Maximum intensity projection of a confocal z-stack of the trunk vasculature of double transgenic Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1a:nEGFP)y7 wild type embryos (A-B) or vegfabmu155 embryos (C-D) at 32 hpf, injected with either control morpholino (A, C) or Cdkn1a/p21 morpholino (B, D). Lateral view; anterior to the left. Scale bars = 100 um.

(E) Quantification of cells per ISV in wt (n=12) and vegfabmu155 (n=10) embryos injected with control or Cdkn1a/p21 morpholino (MO). Dots represent individual embryos; black lines indicate the mean value ±s.d. n.s = not significant; * p>0.05; *** p>0.0003; **** p<0.0001.
(F-I) Maximum intensity projection of a confocal z-stack of the trunk vasculature of 32 hpf double transgenic $Tg(kdrl:Hsa.HRAS-mCherry)_{s916}; Tg(fli1a:nEGFP)_{y7}$ embryos injected with ctr. morpholino (F, H) or cdkn1a/p21 morpholino (G, I) that were also treated with either DMSO (F-G) or 10 uM LY294002 (H-I). Lateral view; anterior to the left. Scale bars = 100 um.

(J) Quantification of cells per ISV at 32 hpf for Ctr. MO + DMSO, Ctr. morpholino + LY294002, cdkn1a/p21 MO + DMSO and cdkn1a/p21 MO + LY294002 (n = 21 embryos in each group); black lines indicate the mean value ±s.d. n.s = not significant; * p>0.05; *** p>0.0003; **** p<0.0001.

**Figure 7. Inhibiting PI3 kinase signaling during retinal angiogenesis reduces endothelial cell proliferation**

(A) Representative confocal micrograph of a vehicle treated P6 retina. Endothelial cell nuclei are labelled in red by ERG, EdU incorporation in blue and overlay of red and blue channels is pseudocolored in green. Boxed area is magnified in (C).

(B) Representative confocal micrograph of a GDC-0941 treated P6 retina. Boxed area is magnified in (D). Scale bar is 150 um.

(C) Magnified image of angiogenic front in vehicle treated retina.

(D) Magnified image of GDC-0941 treated retina.

(E) Magnified image of vehicle treated vein.

(F) Magnified image of GDC-0941 treated vein.
(G) Quantification of percentage of EdU positive ERG positive cells in vehicle or GDC-0941 treated retinas at the angiogenic front. Each dot represents a retina flank. For vehicle treated group n=4 (7 retinas), for GDC-0941 treated group n=5 (10 retinas).

(H) Quantification of percentage of EdU positive ERG positive cells in vehicle or GDC-0941 treated retinas in the vein area. Each dot represents a retina flank. For vehicle treated group n=4 (7 retinas), for GDC-0941 treated group n=5 (10 retinas).

Supplementary Figure S1. Distinct sprouting and proliferation defects in vegfaa or vegfab mutants correlate with vegfaa and vegfab expression domains

(A-D) Fluorescent in situ hybridization combined with an anti-EGFP antibody staining showing the distribution of vegfaa121 (red, A-B), vegfab171 (red, C-D) and EGFP driven by Tg(Kdrl:EGFP)S843 (green, B, D) at 32 hpf. Dorsal views anterior to the left. Arrows indicate the expression domains of vegfaa and vegfab. Scale bar = 100 um.

(E-G) Still images of confocal time-lapse of zebrafish hindbrain development in live Tg(kdrl:Hsa.HRAS-mCherry)S916; Tg(fli1a:nEGFP)y7 embryos between 32 and 42 hpf, shown for wild type (E), vegfaamu128 (F) and vegfabmu155 (G). Dorsal view, anterior to the left, Scale bar = 100 um. White dots mark cells within CtAs derived from proliferation.

(H) Quantification of cell numbers derived from proliferation and total cell numbers in wild type, vegfaamu128 and vegfabmu155 embryos (n = 3 embryos for each group). Dots represent individual embryos; black lines indicate the mean value±s.d. n.s. = not significant; * p>0.05; ** p>0.0022; **** p<0.0001.

(I) Quantification of cells derived from proliferation normalized to the total cell number comparing wild type, vegfaamu128 and vegfabmu155 (n = 3 embryos for each group). Dots
represent individual embryos; black lines indicate the mean value±s.d. n.s = not significant; ** p>0.0022.

Supplementary Figure S2. Analysis of overall morphology and ISV formation in vegfa\textsubscript{mu128} and vegfab\textsubscript{mu155} mutants at 30 hpf

(A, C, E, G and I) Brightfield images of wild type (A), vegfa\textsubscript{mu128} +/- (C), vegfa\textsubscript{mu128} -/- (E) vegfab\textsubscript{mu155} +/- (G) and vegfab\textsubscript{mu155} -/- (I) embryos. (B, D, F, H and J) Maximum intensity projections of confocal z-stacks of the trunk vasculature of Tg(kdrl:EGFP)\textsubscript{s843} wild type (B), vegfa\textsubscript{mu128} +/- (D), vegfa\textsubscript{mu128} -/- (F) vegfab\textsubscript{mu155} +/- (H) and vegfab\textsubscript{mu155} -/- (J) embryos. Lateral views, anterior to the left. Scale bar = 100 um.

(K) Quantification of ISV length from ISV number 1 to number 10 from anterior to posterior of the trunk vasculature of wild type (green), vegfa\textsubscript{mu128} +/- (red), vegfa\textsubscript{mu128} -/- (black) vegfab\textsubscript{mu155} +/- (brown) and vegfab\textsubscript{mu155} -/- (blue) embryos; n = 8. Values are mean±s.d.

Supplementary Figure S3. Overexpression of Vegfab leads to an increase in ISV cell numbers

(A-C) ISVs of uninjected control embryos at 32 hpf. Blood vessels labelled by Tg(Hsa.HRAS-mCherry)\textsubscript{s916} in red (A). Endothelial cell nuclei labelled by Tg(Fli:nEGFP)\textsubscript{y7} in green (B). Overlay of red and green channels (C). Side views, anterior to the left.

(D-F) ISVs of embryos injected with 50pg of vegfab mRNA at 32 hpf. Blood vessels labelled by Tg(Hsa.HRAS-mCherry)\textsubscript{s916} in red (D). Endothelial cell nuclei labelled by
Supplementary Figure S4. PMA treatment of zebrafish embryos leads to ERK phosphorylation
(A-B) Overview pictures of wild type embryos at 32 hpf treated with DMSO (A) or 0.25 uM PMA (B). Scale bar = 400 um.

Supplementary Figure S5. LY294002 treatment of zebrafish embryos leads to a reduction in Akt phosphorylation
(A-B) Brightfield images of single wild type embryos at 32 hpf treated with DMSO (A) or 10 uM LY294002 (B). Lateral views, anterior to the left. Scale bar = 400 um.
(C) Western blot analysis of pAKT, total AKT and Actin in embryos treated with DMSO or 10 uM LY294002. Representative blot of n=3 is shown.
Supplementary Figure S6. GDC-0326 mediated inhibition of PI3K p110 alpha isoform affects endothelial cell numbers

(A) Western blot analysis of pAKT, total AKT and Actin in embryos treated with DMSO or indicated concentrations of GDC-0326. Representative blot of n=3 is shown.

(B-M) Maximum intensity projection of confocal z-stacks of the trunk vasculature of double transgenic Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1a:nEGFP)y7 embryos treated with DMSO (B-D), 10 uM GDC-0326 (E-G), 25 uM GDC-0326 (H-J) or 50 uM GDC-0326 (K-M). Lateral views, anterior to the left. Scale bar = 100 um.

(N) Quantification of cells per ISV in embryos treated with DMSO compared to embryos treated with 10 uM, 25 uM and 50 uM GDC-0326. Dots represent individual embryos (n = 14 embryos for each condition), black lines indicate the mean value ±s.d. *** p>0.0003; **** p<0.0001.

Supplementary Figure S7. Treatment of mouse retinas with GDC-0941 leads to reduction in AKT phosphorylation and S6 phosphorylation

(A) Western blot analysis of pAKT, total AKT and CD144/Cdh5. Representative blot of n=3 is shown.

(B-C) Immunohistochemistry on mouse retina. Staining for isolecitinB4 (blue; blood vessels) and pS6 kinase (red) in vehicle injected control mice (B, C) and GDC-0941 injected mice (D, E). Scale bar is 150 um.
Supplementary Video S1. Development of hindbrain vasculature in wildtype zebrafish embryo

Endothelial cells are marked by virtue of EGFP expression in $Tg(kdrl:EGFP)_{s843}$ zebrafish. Dorsal view of head region, anterior to the left. Imaging starts at 28 hpf and is carried out for 18.5 hours.

Supplementary Video S2. Development of hindbrain vasculature in $vegfa_{mu128}$ zebrafish embryo

Endothelial cells are marked by virtue of EGFP expression in $Tg(kdrl:EGFP)_{s843}$ zebrafish. Dorsal view of head region, anterior to the left. Imaging starts at 28 hpf and is carried out for 18.5 hours.

Supplementary Video S3. Development of hindbrain vasculature in $vegfa_{mu155}$ zebrafish embryo

Endothelial cells are marked by virtue of EGFP expression in $Tg(kdrl:EGFP)_{s843}$ zebrafish. Dorsal view of head region, anterior to the left. Imaging starts at 28 hpf and is carried out for 18.5 hours.

Supplementary Video S4. Development of hindbrain vasculature in wildtype zebrafish embryo

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in $Tg(kdrl:Hsa.HRAS-mCherry)_{s916}$;
Supplementary Video S5. Development of hindbrain vasculature in *vegfa*mut128 zebrafish embryo

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1:nEGFP)y7 zebrafish. Dorsal view of head region, anterior to the left. Imaging starts at 28 hpf and is carried out for 14 hours.

Supplementary Video S6. Development of hindbrain vasculature in *vegfab*mut155 zebrafish embryo

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1:nEGFP)y7 zebrafish. Dorsal view of head region, anterior to the left. Imaging starts at 28 hpf and is carried out for 14.5 hours.

Supplementary Video S7. Endothelial cell proliferation and migration in individual intersegmental blood vessel sprout in wildtype zebrafish embryo

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1:nEGFP)y7 zebrafish. Side view of trunk region, anterior to the left. Imaging starts...
at 22 hpf and is carried out for 6 hours. Individual endothelial cells are marked by arrowheads and numbers. Decimal numbers indicate progeny after division.

Supplementary Video S8. Endothelial cell proliferation and migration in individual intersegmental blood vessel sprout in vegfaamu128 heterozygous zebrafish embryo

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1:nEGFP)y7 zebrafish. This example shows intersegmental vessel with normal endothelial cell behaviors. Side view of trunk region, anterior to the left. Imaging starts at 22 hpf and is carried out for 6 hours. Individual endothelial cells are marked by arrowheads and numbers. Decimal numbers indicate progeny after division.

Supplementary Video S9. Endothelial cell proliferation and migration in individual intersegmental blood vessel sprout in vegfaamu128 heterozygous zebrafish embryo

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1:nEGFP)y7 zebrafish. This example shows a stalled intersegmental vessel. Side view of trunk region, anterior to the left. Imaging starts at 22 hpf and is carried out for 6 hours. Individual endothelial cells are marked by arrowheads and numbers. Decimal numbers indicate progeny after division.
Supplementary Video S10. Endothelial cell proliferation and migration in individual intersegmental blood vessel sprout in vegfabmu155 mutant zebrafish embryo

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1:nEGFP)y7 zebrafish. Side view of trunk region, anterior to the left. Imaging starts at 22 hpf and is carried out for 6 hours. Individual endothelial cells are marked by arrowheads and numbers. Decimal numbers indicate progeny after division.

Supplementary Video S11. Endothelial cell proliferation and migration in intersegmental blood vessel sprouts in wildtype zebrafish embryo

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1:nEGFP)y7 zebrafish. Side view of trunk region, anterior to the left. Imaging starts at 22 hpf and is carried out for 10 hours. Individual endothelial cells are marked by arrowheads and numbers. Decimal numbers indicate progeny after division.

Supplementary Video S12. Endothelial cell proliferation and migration in intersegmental blood vessel sprouts in vegfaamu128 heterozygous embryo

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in Tg(kdrl:Hsa.HRAS-mCherry)s916; Tg(fli1:nEGFP)y7 zebrafish. Side view of trunk region, anterior to the left. Imaging starts
at 22 hpf and is carried out for 10.5 hours. Individual endothelial cells are marked by
arrowheads and numbers. Decimal numbers indicate progeny after division.

Supplementary Video S13. Endothelial cell proliferation and migration in
intersegmental blood vessel sprouts in vegfa<sub>mu155</sub> mutant embryo
Endothelial cell membranes (red) are marked by virtue of mCherry expression, while
endothelial cell nuclei express EGFP (green) in Tg(kdrl:Hsa.HRAS-mCherry)<sub>s916</sub>;
Tg(fli1:nEGFP)<sub>y7</sub> zebrafish. Side view of trunk region, anterior to the left. Imaging starts
at 22 hpf and is carried out for 10.5 hours. Individual endothelial cells are marked by
arrowheads and numbers. Decimal numbers indicate progeny after division.

Supplementary Video S14. Endothelial cell proliferation and migration in
individual intersegmental blood vessel sprout in DMSO treated zebrafish embryo
Endothelial cell membranes (red) are marked by virtue of mCherry expression, while
endothelial cell nuclei express EGFP (green) in Tg(kdrl:Hsa.HRAS-mCherry)<sub>s916</sub>;
Tg(fli1:nEGFP)<sub>y7</sub> zebrafish Side view of trunk region, anterior to the left. Imaging starts
at 22 hpf and is carried out for 6 hours. Individual endothelial cells are marked by
arrowheads and numbers. Decimal numbers indicate progeny after division.

Supplementary Video S15. Endothelial cell proliferation and migration in
individual intersegmental blood vessel sprout in LY294002 treated zebrafish
embryo
Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in \( Tg(kdrl:Hsa.HRAS-mCherry)s916; \)

\( Tg(fli1:nEGFP)z7 \) zebrafish. Side view of trunk region, anterior to the left. Imaging starts at 22 hpf and is carried out for 6 hours. Individual endothelial cells are marked by arrowheads and numbers. Decimal numbers indicate progeny after division.

**Supplementary Video S16. Endothelial cell proliferation and migration in intersegmental blood vessel sprouts in DMSO treated zebrafish embryo**

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in \( Tg(kdrl:Hsa.HRAS-mCherry)s916; \)

\( Tg(fli1:nEGFP)z7 \) zebrafish. Side view of trunk region, anterior to the left. Imaging starts at 22 hpf and is carried out for 10 hours. Individual endothelial cells are marked by arrowheads and numbers. Decimal numbers indicate progeny after division.

**Supplementary Video S17. Endothelial cell proliferation and migration in intersegmental blood vessel sprouts in LY294002 treated zebrafish embryo**

Endothelial cell membranes (red) are marked by virtue of mCherry expression, while endothelial cell nuclei express EGFP (green) in \( Tg(kdrl:Hsa.HRAS-mCherry)s916; \)

\( Tg(fli1:nEGFP)z7 \) zebrafish. Side view of trunk region, anterior to the left. Imaging starts at 22 hpf and is carried out for 10 hours. Individual endothelial cells are marked by arrowheads and numbers. Decimal numbers indicate progeny after division.
