Title: Tocotrienol decreases β-amyloid mediated toxicity in Caenorhabditis elegans model of Alzheimer's disease

Abstract

Alzheimer’s disease (AD) is a neurological disease caused by the accumulation of extracellular senile plaques consisting of β-amyloid peptide (Aβ) in the brain. A transgenic Caenorhabditis elegans which demonstrated paralysis due to the expression of human beta amyloid Aβ42 gene was used to study the anti-paralysis effect of mixed tocotrienols. The content of the mixed tocotrienols were 12.1% α-, 2.7% β-, 18.6% γ-, and 8.1% δ-tocotrienols. Mixed tocotrienols significantly delayed the Aβ-induced paralysis in the transgenic nematode and exhibited anti-oxidant properties towards Aβ-generated oxidative stress. The mixture also presented potent inhibitory activities against Aβ aggregation with an IC₅₀ value of 600 ng/ml. It is concluded that mixed tocotrienols could potentially serve as a new therapeutic candidate for AD.

Key words

Alzheimer’s disease, beta amyloid, C. elegans, tocotrienol, tocotrienol
1.0 Introduction

Alzheimer’s disease (AD) is a progressive neurodegenerative disorder that affects the old age population resulting in the loss in memory loss and decrease muscle strength. The occurrence of this disease is due to the presence of neurofibrillary tangles and senile plaques in the brain (1). Aβ is a protein that aggregates to form fibrils in the human brain and is expressed by a gene in chromosome 21 in humans (2). The manifestation of AD occurs when Aβ amyloid plaques start to materialize in the basal part of the isocortex and subsequently spread to the rest of the isocortex due to progression of AD. At the later stage of AD, the amyloid plaques have covered almost the brain with the highest amyloid plaque density found in the isocortex (3).

Tocotrienols are a group of chemicals forming part of the vitamin E family and normally found in the seed endosperm of many monocotyledons like palm, wheat, rice and barley and some dicotyledons like tobacco (4). Palm oil is one of the natural sources of tocotrienols and approximately 800 mg tocotrienols per kg crude oil can be extracted from it. Mixed tocotrienols has been reported to have potential neuroprotective properties in preventing Aβ aggregation. Inhibition of Aβ42 fibrillogenesis were observed when Aβ42 peptide was exposed to mixed tocotrienols with the composition 19.6% α-, 2.4% β-, 25.5% γ- and 7.5% δ-tocotrienols. Aβ40 and Aβ42 oligomer formations were also suppressed by the mixed tocotrienols. In addition, mixture also reduced Aβ deposition in the brain and significantly improved the cognitive functions of AβPPswe/PS1dE9 double transgenic mice (5).

Transgenic Caenorhabditis elegans containing the human Aβ42 gene have been used as a model in various studies investigating the effect of natural products on Alzheimer’s disease (6). The short life span of the nematode, easy maintenance and
its concomitant progressive paralysis phenotype makes it favorable as a model. In addition, it has the ability to develop muscle-associated deposits reactive to amyloid-specific dyes. It is also experiencing \( \text{A}\beta_{42} \)-induced oxidative stress (7). Thus far, no study on the effects of tocotrienol on the transgenic \textit{C. elegans} has ever documented. Hence, the objective of this paper is to demonstrate the efficacies of mixed tocotrienols extracted from \textit{Elaeis guineensis} (oil palm) in attenuating \( \text{A}\beta \)-mediated toxicity in transgenic nematodes that carry the \( \text{A}\beta_{42} \) protein gene.

2.0 Methods and Materials

2.1 \textit{C. elegans} strains and Maintenance

Transgenic \textit{C. elegans} strain GMC101 (dvIs100 [unc-54p::A-beta-1-42::unc-54 3'-UTR + mtl-2p::GFP]), \textit{C. elegans} strain CL2122 (dvIs15 [(pPD30.38) unc-54(vector) + (pCL26) mtl-2::GFP]) and \textit{E. coli} OP50 strain were kindly provided by the Caenorhabditis Genetics Center (CGC), University of Minnesota (Minneapolis, MN, USA). The \textit{C. elegans} strain were maintained at 16 °C on nematode growth medium (NGM) seeded with \textit{E. coli} OP50 bacteria. GMC101 is a transgenic strain that expressed the human \( \text{A}\beta_{42} \) gene while CL2122 does not have the human \( \text{A}\beta_{42} \) gene.

2.2 \textit{C. elegans} paralysis assays

Paralysis assays were performed as described by McColl et al. (8) with a slight modification. All populations were cultured at 16°C on 60 mm NGM plates with 250 μl of overnight \textit{E. coli} OP50 bacterial culture pre-spread on the plates. After a 4-hour egg-laying period on NGM plates at 16°C, either-in the absence or presence of the compounds, the \textit{C. elegans} populations were developmentally synchronized by shifting the incubation temperature to 25°C at 72 hours post-egg lay. Time zero was
defined at this point of temperature shift. The body movement of the nematodes were assessed over time by scoring as “paralysed” if they failed to show complete full body movement, either spontaneously or touch-provoked. The proportion of individuals that were not paralysed was calculated. Three independent experiments were performed in all studies. A range of different concentrations of mixed tocotrienols (0.25%-1.00%) from the oil palm *Elaeis guineensis* (from ExcelVite Pty Ltd) were used to treat the nematodes.

2.3 Measurement of reactive oxygen species (ROS) in *C. elegans*

The levels of ROS were measured in vivo by using the 2,7-dichlorofluorescein diacetate method described by Gutierrez-Zepeda *et al.* (7) with a modification in which the worms were incubated at 37°C between reads to simulate human body temperature. Readings were taken every 20 minutes. To initiate Aβ-induced paralysis, the live worms were shifted to an incubator set at 25°C. Approximately 100 worms were harvested at 32 hrs after temperature shift using M9 buffer. The worms were resuspended in M9 buffer with 100 μM DCFH-DA (Sigma-Aldrich, Missouri, USA). They were then transferred into the wells of a 96-well non-binding black microplate (Greiner Bio-One) and the fluorescence was read every 20 minutes at an excitation wavelength of 485nm and an emission wavelength of 520nm using a fluorescence microplate reader (EnVision 2104 Multilabel Reader (Perkin Elmer, MA, USA)).

2.4 Immuno-dot blot assay of Aβ

The levels of Aβ proteins were analysed using the immuno-dot blot analysis. Samples were then extracted in 3 volumes of urea buffer (7 M urea, 2 M Thiourea, 4% w/v CHAPS, 1.5% w/v dithiothreitol and 50 mM Tris pH 8.0), disrupted via sonication and subsequently centrifuged at 13,000 xg for 10 min. Total proteins were spotted (10
μg) onto nitrocellulose membranes (Merck Millipore, Darmstadt, Germany) and left to dry. The membranes were incubated with a blocking solution [skim milk (Sunlac) with 0.1% tween-20-phosphate buffered saline] for one hour. This was followed by an incubation period with Anti-Aβ mouse monoclonal antibody 6E10 (1:1000, epitope: Aβ3-8, Biolegend, San Diego) and peroxidase-conjugated anti-mouse IgG (1:1000, Bio-Rad, California) which acted as the primary and secondary antibodies, respectively. The spots were viewed using the colorimetric method available in Opti4CN™ Substrate Kit (Bio-Rad, California).

2.5 Aβ Aggregation assay

The procedure was performed as described by the manufacturer’s instructions (SensoLyte ® Thioflavin T Beta Amyloid (1-42) Aggregation Kit (Anaspec)). Approximately 10 μl of 2mM ThT, 85μL of Aβ42 peptide and 5μL of the bioactive compounds at selected concentrations were added into each well. The plates were read every 10 minutes on a fluorescence microplate reader (EnVision 2104 Multilabel Reader (Perkin Elmer, MA, USA) at an excitation wavelength of 440nm with an emission wavelength of 484nm.

3.0 Results

Paralysis of the worms were significantly delayed when worms were treated at 0.5 (50 μg/ml) %, 0.75% (75 μg/ml) and 1% (100 μg/ml) of mixed tocotrienols (p<0.05) (Figure 1 A and B). The lower percentage of tocotrienols (0.125% - 0.25%) did not significantly reduce paralysis.

Aggregation assay using thioflavin T dye was used to measure Aβ42 aggregation in the presence of mixed tocotrienols. Concentrations of 200 ng/ml, 400 ng/ml, 600 ng/ml and 800 ng/ml of mixed tocotrienols were used to test their ability to
produce anti-aggregation properties towards Aβ_{42} (Figure 2 A).

Significant inhibition of Aβ fibrils formation was observed for 600 ng/ml and 800 ng/ml of mixed tocotrienols (p<0.05) compared to the two lower concentrations (Figure 2 A). The IC_{50} for the inhibition of Aβ aggregation by tocotrienols was 600 ng/ml (see Figure 2 B).

Tocotrienols are known to have antioxidant properties and were therefore tested using dichloro-dihydro-fluorescein diacetate (DCFH-DA) assay. This study showed the potential of mixed tocotrienols in reducing Aβ-induced ROS production (Figure 3 A). The worms were harvested at 32 hours after temperature upshift to observe the differences in ROS productions between the worms treated with mixed tocotrienols and the untreated. As shown in Figure 3 B, tocotrienols mixture demonstrated the potential in reducing the ROS production but did not totally negate it. Worms treated with 0.5 % -1 % mixed tocotrienols showed significantly reduced ROS production. The results were in correlation with the anti-paralysis assays. Based on Figures 4 and 5, 1 % mixed tocotrienols (equivalent to 100μg/ml mixed tocotrienols) affected the Aβ_{42} gene expression compared to methanol (used as the vehicle) but did not statistically significant decrease the Aβ_{42} levels (p>0.05).

4.0 Discussion

A palm oil extract comprising mixed tocotrienols with a combination of 12.1% α-, 2.7% β-, 18.6% γ- and 8.1% δ-tocotrienols was evaluated for its neuroprotection activities. Based on the paralysis assays on a C. elegans transgenic strain that expressed Aβ proteins, mixed tocotrienols delayed amyloid-induced paralysis. A study had shown that mixed tocotrienols with the combinations of 19.6% α-, 2.4% β-, 25.5% γ- and 7.5% δ-tocotrienols had disrupted the Aβ oligomers and Aβ fibrils from
being formed (5). In addition, Aβ depositions and fibrillar type plaques were reduced in the brains of mixed tocotrienols treated AβPPswe/PS1dE9 double transgenic mice (5). Cognitive function of the treated mice had also improved in the object recognition test as compared to control AβPPswe/PS1dE9 mice (5). Hence, it can be concluded that mixed tocotrienols had decreased amyloid pathology and improved cognitive functions.

For the in vitro study, the tocotrienols act directly towards the Aβ_{42} proteins and therefore the concentrations of tocotrienols used was lower than the concentrations used in the tocotrienol studies on the nematodes. The concentrations used on the worms were higher considering that the entry route was by ingestion and subsequent metabolism of the compounds would occur.

Mixed tocotrienols with combinations of 10.8% α-, 22.0% γ- and 5.2% δ-tocotrienols was shown to prevent hydrogen peroxide-induced death in rat striatal neuron cells. The minimal concentration that showed anti-H_{2}O_{2}-induced neurotoxicity properties for α-, γ- and δ-tocotrienols were 0.1, 1 and 10 μmol/L, respectively (9). The lowest dosage of mixed tocotrienols that posed anti-paralysis effects to the transgenic GMC101 strain was 0.5% mixed tocotrienols which was equivalent to 50 μg/ml. Thus, it can be deduced that tocotrienols have antioxidant properties.

In another study, protein oxidation was reduced in 15-day old C. elegans that was treated with mixed tocotrienols with the contents of 24% α-, 37% γ- and 12% δ-tocotrienols (10). In addition, protein oxidation was effectively inhibited in skeletal muscles of rats when rats were treated with tocotrienols supplements (11). In the present work, mixed tocotrienols with 12.1% α-, 2.7% β-, 18.6% γ-, and 8.1% δ-tocotrienols had reduced Aβ_{42}-induced oxidative stress in the transgenic C. elegans.
5.0 Conclusion

In this study, we found that tocotrienol treatment towards *C. elegans* expressing human Aβ42 gene showed positive response. From the analysis, paralysis was delayed when *C. elegans* was treated with tocotrienol. In addition, tocotrienol also inhibits the formation of Aβ fibrils as well as reducing Aβ-induced ROS production in *C. elegans*. Through this study, we infer that tocotrienol has the potential to be an alternative drug to combat Alzheimer’s disease.
