ABSTRACT

The infection of SARS-CoV-2 has spread to more than 200 countries and regions and the numbers of infected people and deaths worldwide are expected to continue to rise. Current treatment of COVID-19 is limited and mostly supportive. At present, there is no specific therapeutics against SARS-CoV-2. In this study, we discovered that protoporphyrin IX and verteporfin, two FDA-approved drugs for treatment of human diseases, had significant antiviral effect against SARS-CoV-2, with EC50 values for the reduction of viral RNA at nanomolar concentrations. Both drugs completely inhibited the cytopathic effect (CPE) produced by SARS-CoV-2 infection at lower drug concentrations than that of remdesivir. The selection indices of protoporphyrin IX and verteporfin are 952.74 and 368.93, respectively, suggesting wide safety margins. Both drugs were able to prevent SARS-CoV-2 infection as well as suppress established SARS-CoV-2 infection. The compounds share a porphyrin ring structure. Molecular docking indicates that the compounds may interact with viral receptor ACE2 and could block the cell-cell fusion mediated by ACE2 and viral S protein. Our finding suggests that protoporphyrin IX and verteporfin might be potential antivirals against SARS-CoV-2 infection and also sheds new light on the development of a novel class of small compounds against SARS-CoV-2.

INTRODUCTION

The infection of SARS-CoV-2 (Severe Acute Respiratory Syndrome Coronavirus 2) has spread to more than 200 countries and regions since December 2019. As of April 24, 2020, there are nearly 2.7 million confirmed cases globally, of which more than 190,000 died. Although the development of the pandemic has been contained or alleviated in some countries, the numbers of infected people and deaths worldwide are expected to continue to rise.

SARS-CoV-2 is transmitted through respiratory droplets and close contact, which causes mainly upper and lower respiratory diseases. The majority of infected healthy
adults and children only show mild symptoms including cough, fever, fatigue and diarrhea but the elderly with various chronic diseases are at high risk of development of serious diseases including pneumonia, acute respiratory distress, multiple organ failure and shock. At present, the main treatment of Corona Virus Disease 2019 (COVID-19) is supportive, including non-specific antivirals and symptom-alleviating therapies. Ventilations and intensive care are required for severe cases, calling for early intervention to prevent symptoms from deteriorating.

At present, there is no specific therapeutics against SARS-CoV-2. An earlier case report demonstrated the potential effectiveness of remdesivir in the experimental treatment of an American COVID-19 patient. In vitro experiment showed that remdesivir effectively inhibited SARS-CoV-2 replication. The recent data on the compassionate use of remdesivir for patients with severe COVID-19 indicated that clinical improvement was observed in 36 of 53 patients (68%). Several drugs in clinical use for other diseases have been tested in vitro for inhibition of SARS-CoV-2 infection and some of them are in clinical trial. Among them, chloroquine and its derivative hydroxychloroquine have drawn intensive debate. Chloroquine and hydroxychloroquine have been shown to inhibit SARS-CoV-2 infection in vitro while the clinical trials of hydroxychloroquine reported controversial results. Traditional Chinese medicine (TCM) has also been extensively used in the treatment of COVID-19 in China though the direct antiviral effect of TCM awaits investigation. It should be noted that the effective concentrations (generally EC50 for the reduction of viral RNA) of most previously selected drugs are in the micromolar (µM) concentration range and the selection indices reflecting drug safety leave much to be improved. Effective antivirals with good safety profile are urgently needed.

In this study, we discovered that protoporphyrin IX and verteporfin, two FDA-approved drugs that are being used in treatment of human diseases, had significant antiviral effect against SARS-CoV-2, with EC50 values for the reduction of viral RNA at nanomolar concentrations. Both drugs completely inhibited the
cytopathic effect (CPE) produced by SARS-CoV-2 infection at lower drug concentrations than that of remdesivir. The selection indices of the two drugs are 952.74 and 368.93, respectively, suggesting wide safety margins. The mechanism of the antiviral effect of protoporphyrin IX and verteporfin has been explored. The compounds interact with viral receptor ACE2 as revealed by molecular docking and might interfere with the interaction between ACE2 and viral S protein.

MATERIALS AND METHODS

Cell line, virus and compounds

African green monkey kidney Vero-E6 cell line was cultured at 37°C with 5% CO₂ in Dulbecco’s modified Eagle medium (DMEM) (Gibco, Carlsbad, USA) containing 2 mmol/L L-glutamine, 50 U/mL penicillin, 100 mg/mL streptomycin, and 10% (vol/vol) fetal bovine serum (Gibco). Vero-E6 cells after SARS-CoV-2 infection were maintained with DMEM containing 2 mmol/L L-glutamine, 50 U/mL penicillin, 100 mg/mL streptomycin, and 2% (vol/vol) fetal bovine serum.

A clinical isolate of SARS-CoV-2, nCoV-SH01 (GenBank: MT121215.1) was propagated in Vero-E6 cells and viral titer was determined as plaque forming units (PFU) per milliliter (mL) by CPE quantification. All the infection experiments were performed in the biosafety level-3 (BSL-3) laboratory of Fudan University.

Custom compound libraries containing 3200 small molecules were purchased from Target Mol (MA, USA). Protoporphyrin IX (CAS No.: 553-12-8), verteporfin (CAS No.: 129497-78-5) and remdesivir (CAS No.:1809249-37-3) were purchased from MedChemExpress (NJ, USA).

Cell cytotoxicity assay

The Cell Counting Kit-8 (Dojindo, Kumamoto, Japan) was used to assess cell viability according to the manufacturer’s instructions. Briefly, Vero-E6 cells were dispensed into 96-well plate (1.0 x 10⁴ cells/well), cultured in medium supplemented with the compound of different concentrations for 48 hours. After removal of the
medium, the cells were incubated with fresh serum-free medium containing 10% CCK-8 for 1 hour at 37°C and then the absorbances at 450 nm were measured using a microplate reader (Bio-Rad, Hercules, USA).

**Library screening**

Custom compound libraries were screened via observation of CPE. Vero-E6 cells cultured in 96-well plate (4.0 x 10⁴ cells/well) were incubated with medium containing 200 PFU SARS-CoV-2/well and each compound (10 μM). Remdesivir (10 μM) served as positive control and DMSO as solvent control. CPE was observed under microscope every 24 hours for 72 hours.

**Evaluation of antiviral effect of the compounds**

Vero-E6 cells cultured in 96-well plate (4.0 x 10⁴ cells/well) were pre-treated with the compound of a tested concentration or DMSO for 1 hour. SARS-CoV-2 (200 PFU/well) diluted in medium supplemented with the compound of the corresponding concentration was added to allow viral infection for 1 hour at 37°C. The mixture was removed and cells were washed twice with PBS, followed by culture with fresh medium containing the compound of the corresponding concentration. At 48 hours post infection, culture supernatant was collected for viral RNA quantification and the cells were fixed in 4% paraformaldehyde for immunofluorescence analysis.

To evaluate the relationship between the timing of compound addition and the antiviral efficacy, Vero-E6 cells cultured in 96-well plate (4.0 x 10⁴ cells/well) were treated with protoporphyrin IX (2.5 μM), verteporfin (1.25 μM) or DMSO at different timepoints relative to virus infection (Fig. 2a). Briefly, four sets of cells (I-IV) were pre-treated with the compound for 1 hour prior to virus infection. The medium was discarded and the cells were washed twice with PBS. Two sets (I, II) were then incubated with medium containing SARS-CoV-2 (200 PFU/well) and the compound for 1 hour and the other two sets (III, IV) were incubated only with the virus. After the removal of the virus and wash with PBS, set I and III were cultured with fresh
medium containing the compound while set II and IV in medium without the compound. Four more sets of cells (V-VIII) were set up similarly except the initial culture medium contains DMSO instead of the compound. At 48 hours post infection, culture supernatant was collected for viral RNA quantification and cells for immunofluorescence analysis.

For evaluation of the prevention of viral infection by the compounds, Vero-E6 cells plated in 96-well plate (4.0 x 10^4 cells/well) were pre-treated with protoporphyrin IX (2.5 μM), verteporfin (1.25 μM) or DMSO for 1 hour. The compound was removed and cells were washed with PBS twice. Subsequently, the cells were incubated with medium containing an increasing dose of SARS-CoV-2 for 1 hour. After removal of the virus and wash with PBS, cells were cultured for 48 hours for immunofluorescence analysis.

**Viral RNA extraction and quantitative real time PCR (qRT-PCR)**

Viral RNA in cell supernatant was extracted using TRIzol reagent (Invitrogen, Carlsbad, USA) following the manufacturer’s instructions. After phenol/chloroform extraction and isopropanol precipitation, RNA was reverse transcribed using cDNA Synthesis Kit (Tiangen, Shanghai, China) according to the manufacturer’s instructions. Quantitative real-time PCR (qRT-PCR) was performed in a 20 μL reaction containing SYBR Green (TaKaRa, Kusatsu, Japan) on MXP3000 cycler (Stratagene, La Jolla, USA) with the following program: initial denaturation at 95°C for 300 seconds; 40 cycles of 95°C for 15 seconds, 55°C for 20 seconds, and 72°C for 20 seconds; followed by a melt curve step. PCR primers (Genewiz, Suzhou, China) targeting SARS-CoV-2 N gene (nt608-706) were as following(forward/reverse): 5’-GGGGAACTTCTCCTGCTAGAAT-3’/5’-CAGACATTTTGCTCTCAAGCTG-3’.

**Immunofluorescence analysis**

To detect the viral nucleocapsid protein (N protein), anti-N polyclonal antibodies were
generated using standard immunization of Balb/C mice with recombinant N protein derived from *E. coli*. Vero-E6 cells grown in 96-well plate were fixed in 4% paraformaldehyde, permeabilized by 0.2% Triton X-100 (Thermo Fisher Scientific, Waltham, USA), blocked with 3% BSA, and stained overnight with the anti-N antibody (1:1000) at 4°C. The samples were finally incubated with Alexa Fluor donkey anti-mouse IgG 488-labeled secondary antibody (1:1000, Thermo Fisher Scientific) for 1 hour at 37°C. The nuclei were stained with DAPI (Thermo Fisher Scientific). Images were captured with fluorescence microscopy (Thermo Fisher Scientific).

**Molecular docking**

Cryo-electron microscopy structures of the full-length human ACE2 and a neutral amino acid transporter B0AT1 complex with an overall resolution of 2.9 Å have been reported 14. The structure files were downloaded from Protein Data Bank (PDB ID: 6m18). Meanwhile, the structures of the compounds, protoporphyrin IX and verteporfin, were obtained from the EMBL-EBI and PubChem compound databases. The receptor-ligand docking of the ACE2 protein with protoporphyrin IX or verteporfin was performed by using AutoDock 4.2.6 software and visualized with AutoDockTools 1.5.6 software (http://autodock.scripps.edu). Firstly, the ligand and receptor coordinate files were prepared respectively to include the information needed by AutoDock and the PDBQT files were created. Then the three-dimension of the grid box was set in AutoDockTools to create the grid parameter file. Afterwards, AutoGrid was used to generate the grid maps and AutoDock was run for receptor-ligand docking. After docking was completed, the results were shown in AutoDockTools, then the binding energy and receptor-ligand interactions were evaluated. The docking area was displayed in VMD 1.9.3 software (http://www.ks.uiuc.edu/Research/vmd).

**Cell-cell fusion assay**

Cell-cell fusion was performed as described previously 15. Briefly, target HEK293T cells were transiently co-transfected with pCMV-eGFP and pcDNA3.1-ACE2 via
polyethylenimine (PEI). Effector HEK293T cells were generated by transfection with envelope-expressing plasmid of pCAGGS-SARS-CoV-2-S. At 24 hours post transfection, the effector cells were pre-treated with protoporphyrin IX (2.5 μM), verteporfin (1.25 μM) or DMSO for 1 hour, then the compound was removed and cells were washed with PBS twice. The target cells were quickly trypsinized and added to adherent effector cells in a 1:1 effector-to-target cell ratio. After a 4-hour cocultivation period, five fields were randomly selected in each well to count the number of fused and unfused cells under an inverted fluorescence microscope.

Statistical analysis

Data were analyzed using Prism 7 (GraphPad) and are presented as mean ± SEM. The dose response curves of viral RNA levels or cell viability versus the drug concentrations were plotted and evaluated by Prism 7. Statistical significance was determined using the unpaired two-tailed Student’s t test for single variables and two-way ANOVA followed by Bonferroni posttests for multiple variables. A P value of <0.05 was considered statistically significant and is presented as *** (P < 0.001).

RESULTS

Effective inhibition of SARS-CoV-2 infection by protoporphyrin IX and verteporfin

A compound library of 3200 small molecules was screened via observation of viral CPE in Vero-E6 cells for novel antivirals that can effectively inhibit SARS-CoV-2 infection. Two compounds, protoporphyrin IX and verteporfin, showed a complete suppression of viral CPE at 1.25 μM and 0.31 μM respectively (Fig. 1b). These two compounds were subject to further analysis. At 48 hours post-infection, viral RNA level in the supernatant of the cells treated with the compound was measured using qRT-PCR, which decreased dose-dependently as compound concentration was increased. Based on the RNA level-compound concentration curve, the EC50 values of protoporphyrin IX, verteporfin and the positive control remdesivir were calculated.
to be 0.23 µM, 0.03 µM, and 1.35 µM (Fig. 1a), respectively. The EC50 of remdesivir was comparable to the previous report. Cell viability assay was also performed and a viability-compound concentration curve was drawn (Fig. 1a), from which the CC50 values of protoporphyrin IX, verteporfin and remdesivir were determined to be 219.13 µM, 10.33 µM, and 303.23 µM, respectively. The selection indices (S.I.) for the three compounds could thus be calculated as 952.74, 368.93, and 224.61, respectively. Viral N protein expression in infected Vero-E6 cells was assessed by immunofluorescence. The data revealed the complete inhibition of N protein expression by protoporphyrin IX, verteporfin and remdesivir at 1.25 µM, 0.31 µM, and 6.25 µM, respectively (Fig. 1b). The results indicate that protoporphyrin IX and verteporfin strongly inhibit the infection of SARS-CoV-2 at nanomolar concentrations and have a wide safety range in vitro.

**Effects of treatment timing on protoporphyrin IX and verteporfin’s inhibition of SARS-CoV-2 infection**

We next analyzed the relationship between the antiviral effect and treatment timing of protoporphyrin IX and verteporfin. As shown in Fig. 2a, Vero-E6 cells were treated with protoporphyrin IX, verteporfin or the solvent DMSO before viral infection, during viral entry and after viral entry. A total of 8 treatment groups were set up for each compound (group I-VIII). Based on the previous results, we selected the compound concentrations of 2.5 µM and 1.25 µM for protoporphyrin IX and verteporfin, respectively. At 48 hours post infection, viral RNA level in the cell supernatant was quantified with qRT-PCR. The results showed that viral RNA levels of all the compound-treated groups (group I-VII of each compound in Fig. 2b, 2c) were significantly lower than that of the DMSO-treated group (group VIII in Fig. 2b, 2c). Importantly, pre-treatment alone resulted in the complete inhibition of SARS-CoV-2 infection (group IV in Fig. 2b, 2c). In addition, treatment of cells with protoporphyrin IX or verteporfin after viral infection also inhibited viral RNA production, albeit to different extent (group VII in Fig. 2b, 2c). The results of immunofluorescence analysis on intracellular viral N protein were consistent with
those of viral RNA measurement (Fig. 2d). Collectively, the results indicate that protoporphyrin IX and verteporfin can prevent SARS-CoV-2 infection as well as suppress established SARS-CoV-2 infection.

The preventive effect was further tested by the pre-treatment of cells with either compound at a constant concentration and later infection with an increasing virus titer (Fig. 3a). As shown in Fig. 3b, no viral N protein expression was detected in protoporphyrin IX or verteporfin pre-treated cells even if the inoculated viral titer was raised by 16 folds (200 PFU - 3200 PFU).

**Protoporphyrin IX and verteporfin may interact with human ACE2 protein**

Protoporphyrin IX and verteporfin share a same porphyrin-ring structure (Fig. 4a) and thus likely act through a common antiviral mechanism. One possibility prompted by the pre-treatment/preventive results was the saturation or modification of an essential cellular factor(s) required for viral infection. We thus investigated by molecular docking analysis whether ACE2, the viral receptor, might be the target of the compounds. The ACE2 peptidase domain (PD) from the human ACE2-B^0^AT1 complex (PDB ID: 6m18) was used for docking with protoporphyrin IX and verteporfin (Fig. 4a). The result with the highest ranking is exhibited in Fig. 4b, which represents the molecular model of protoporphyrin IX or verteporfin binding to PD. Protoporphyrin IX is located in the shallow-pocket-like space in the PD, with a binding energy of -5.60 kcal/mol. Similar result was obtained from the docking of verteporfin with PD (with a binding energy of -5.35 kcal/mol). Fig. 4c provides a view of the interaction of protoporphyrin IX or verteporfin with ACE2 PD residues. In the model, 25 residues of the PD interacted with protoporphyrin IX, in which the benzene ring of Phe^{40} interacted closely with the porphyrin-ring of protoporphyrin IX, the Trp^{69} formed aromatic H-bonds with the porphyrin-ring, Asp^{350} and Asp^{382} formed H-bonds with the compound. The other residues involved in the interaction with protoporphyrin IX included Ser^{43}, Ser^{44}, Ser^{47}, Asn^{51}, Gly^{66}, Ser^{70}, Leu^{73}, Thr^{347}, Ala^{348}, Trp^{349}, Leu^{351}, Gly^{352}, Phe^{356}, His^{378}, Ile^{379}, Tyr^{385}, Phe^{390}, Leu^{391}, Arg^{393},
Asn\textsuperscript{394} and His\textsuperscript{401}. Similar results were observed in the interaction between verteporfin and PD, except that Asn\textsuperscript{51} formed additional H-bonds with the benzazole-like structure of verteporfin. Many of these PD residues are located in the region that interacts with SARS-CoV-2 S protein receptor binding domain (RBD), especially Phe\textsuperscript{40}, Ser\textsuperscript{43}, Ser\textsuperscript{44}, Trp\textsuperscript{349} - Gly\textsuperscript{352} and Phe\textsuperscript{356}, which are very close to the key residues (Tyr\textsuperscript{41}, Gln\textsuperscript{42}, Lys\textsuperscript{353} and Arg\textsuperscript{357}) that interact with the RBD\textsuperscript{14}. The results suggest that protoporphyrin IX and verteporfin might interact with ACE2.

**Protoporphyrin IX and verteporfin block cell-cell fusion mediated by SARS-CoV-2 S protein and ACE2**

We tested the activity of protoporphyrin IX and verteporfin in interference with ACE2-S interaction using a cell-cell fusion assay system. HEK293T cells that express SARS-CoV-2 S protein served as the effector cells and those co-expressing human ACE2 and eGFP as the target cells (Fig. 4d). The target cells were pre-treated with protoporphyrin IX (2.5 \( \mu \text{M} \)), verteporfin (1.25 \( \mu \text{M} \)) or DMSO for 1 hour. After removal of the drug, the target and effector cells were co-cultured at 37\( ^\circ \text{C} \) for 4 hours. Fused cells with larger cell size than normal cells were observed in the DMSO-treated group but barely in the protoporphyrin IX or verteporfin-treated group. The results indicate that protoporphyrin IX and verteporfin may block the cell-cell fusion mediated by the interaction of ACE2 and viral S protein.

**DISCUSSION**

Protoporphyrin IX and verteporfin have been approved and used in the treatment of human diseases. Protoporphyrin IX is the final intermediate in the protoporphyrin IX iron complex (heme) biosynthetic pathway\textsuperscript{16}. Heme is an important cofactor for oxygen transfer and oxygen storage\textsuperscript{17} and is a constituent of hemoproteins which play a variety of roles in cellular metabolism\textsuperscript{18}. The light-activable photodynamic effect of protoporphyrin IX was used for cancer diagnosis\textsuperscript{19} and approved by FDA for treatment of bronchial and esophageal cancers and early malignant lesions of the skin,
bladder, breast, stomach, and oral cavity. Verteporfin was approved for the treatment of age-related macular degeneration. The potential of verteporfin for the treatment of cancers, such as prostatic cancer, breast cancer, and pancreatic ductal adenocarcinoma has been investigated. Verteporfin also has been reported to inhibit autophagy at an early stage by suppressing autophagosome formation. Our study discovered potent antiviral effects of protoporphyrin IX and verteporfin on SARS-CoV-2 infection. The effective concentrations of these drugs are in the nanomolar concentration range. In addition, the selection indices of both drugs are greater than 200, indicating better safety margins. Nevertheless, this study was performed with Vero-E6 cell culture system. The antiviral efficacy of protoporphyrin IX and verteporfin in vivo will need clinical evaluation.

Both protoporphyrin IX and verteporfin have a porphyrin ring structure formed by four pyrrole rings. It can be deduced that they share a similar mechanism of antiviral action. In the experiment when either drug was added prior to viral infection, viral RNA production was inhibited even if the relevant drug was not added in the later virus infection and post-infection stages (group IV in Fig. 2b, 2c). Furthermore, increasing viral titer did not relieve the inhibition of the drugs added before viral infection (Fig. 3b). A logical hypothesis is that both drugs act by inhibiting an early step in viral infection. Structural simulation by molecular docking supports the binding of both drugs to viral receptor ACE2. Several residues on ACE2 predicted to interact with the drugs are very close to the key residues that interact with the RBD of viral S protein. Based on the molecular docking and experimental data, both drugs are likely to bind ACE2, which might interfere with the interaction between ACE2 and the RBD and impairs viral entry. The mechanism was also supported by the blocking effect of both drugs on the cell-cell fusion mediated by the interaction of ACE2 and viral S protein. More detailed mechanism warrants further study. The study suggests a new venue for the development small molecule-based entry inhibitor against SARS-CoV-2.
On the other hand, protoporphyrin IX and verteporfin were able to inhibit viral RNA production when they were added after viral infection (group VII in Fig. 2b, 2c). Although it is possible that the drugs might inhibit the infection of progeny viruses and prevent virus spreading, the absence of N protein expression in post-infection verteporfin-treated cells suggests that there may also be intracellular antiviral mechanism. Whether the drugs stimulate an antiviral innate immune response also needs exploration.

In conclusion, our study demonstrate the potent antiviral activities of protoporphyrin IX and verteporfin against SARS-CoV-2 infection and also shed new light on the development of novel antivirals against SARS-CoV-2.
