30 **Keywords**

Phosphodiesterase 4B, UCR2, Molecular dynamics simulation, Principal component analysis, Distance cross correlation matrix

31 **Abstract**

32 Phosphodiesterase 4B (PDE4B) is a potential therapeutic target for the inflammatory
33 respiratory diseases such as congestive obstructive pulmonary disease (COPD) and
34 asthma. The sequence identity of ~88% with its isoform PDE4D is the key barrier in
35 developing selective PDE4B inhibitors which may help to overcome associated side
36 effects. Despite high sequence identity, both isoforms differ in few residues present in
37 N-terminal (UCR2) and C-terminal (CR3) involved in catalytic site formation.
38 Previously, we designed and tested specific PDE4B inhibitors considering N-terminal
39 residues as a part of the catalytic cavity. In continuation, current work thoroughly
40 presents an MD simulation-based analysis of N-terminal residues and their role in
41 ligand binding. The various parameters viz. root mean square deviation (RMSD),
42 radius of gyration (Rg), root mean square fluctuation (RMSF), principal component
43 analysis (PCA), *dynamical cross-correlation matrix (DCCM)* analysis, secondary
44 structure analysis, and residue interaction mapping were investigated to establish
45 rational. Results showed that UCR2 reduced RMSF values for the metal binding
46 pocket (31.5 ± 11 to 13.12 ± 6 Å²) and the substrate-binding pocket (38.8 ± 32 to 17.3 ± 11
47 Å²). UCR2 enhanced anti-correlated motion at the active site region that led to the
48 improved ligand-binding affinity of PDE4B from -24.57 ± 3 to -35.54 ± 2 kcal/mol. Further,
49 the atomic-level analysis indicated that T- π and π - π interactions between inhibitors
50 and residues are vital forces that regulate inhibitor association to PDE4B with high
51 affinity. In conclusion, UCR2, the N-terminal domain, embraces the dynamics of
52 PDE4B active site and stabilizes PDE4B inhibitor interactions. Therefore the N-
53 terminal domain needs to be included by designing next-generation, selective PDE4B-
54 inhibitors as potential anti-inflammatory drugs.

55 1. Introduction

56 Respiratory inflammatory diseases such as congestive obstructive pulmonary disease
57 (COPD) and asthma affect millions worldwide (Zhang, Ibrahim, Gillette & Bollag 2005).
58 Phosphodiesterase 4B (PDE4B) is a potential therapeutic target in inflammatory
59 diseases. It hydrolyzes cyclic adenosine monophosphate (cAMP), an important
60 secondary messenger, to 5'-adenosine monophosphates (AMP). AMP is a potent pro-
61 inflammatory mediator in humans, and thus PDE4B regulates many biological
62 processes inside the cell by regulating the production of AMP (Houslay & Adams
63 2003). Therefore, PDE4B inhibitors that prevent cAMP hydrolysis are much needed.
64 The PDE4 enzyme family consists of four members (named PDE4A, PDE4B, PDE4C,
65 and PDE4D), and the mechanism of cAMP catabolism is conserved among all the four
66 PDE4 enzymes. These PDE4 enzymes are highly expressed in neutrophils,
67 monocytes, central nervous system, and smooth muscles of the lung. Available non-
68 selective PDE4 inhibitors like rolipram cause severe side effects such as nausea and
69 emesis. As an improvement, the second-generation PDE4 inhibitors like roflumilast
70 show fewer side effects; however, they are associated with a narrow therapeutic
71 window. Knockout studies in mice suggest that available PDE4B inhibitors co-inhibit
72 PDE4D, a close homologous enzyme, thus causing
73 severe side effects (Wang et al. 1997; Calverley et al. 2009). Therefore, selective
74 inhibition of PDE4B is much needed to develop safe anti-inflammatory drugs.
75 Nonetheless, the high sequence (and thus structural) similarity between the two
76 enzymes, PDE4B and PDE4D, sets hurdles to design and develop selective PDE4B
77 inhibitors.

78
79 The structural comparison of the two enzymes, PDE4B and PDE4D, reveals that the
80 active site cavity is composed of residues from the catalytic domain and a regulatory
81 domain. These regulatory domains include the N-terminal, upstream conserved region
82 2 (UCR2) domain, and the C-terminal regulatory domain (Rocque et al. 1997). Either
83 of these two regulatory domains can cover the catalytic cavity, and thus, provide
84 selectivity for PDE4B inhibition. Contrary to the role of UCR2 in PDE4B inhibition, the
85 UCR2 domain does not affect the substrate affinity (K_m) of PDE4B, as shown by
86 similar K_m values for the 'long-', and the 'catalytic-' versions of PDE4B (Saldou et al.
87 1998). In this work, we have focused on studying the structural effect of the regulatory

88 N-terminal domain, UCR2, on PDE4B inhibition. While a catalytic domain is
89 conserved, with an RMSD value of 0.352 (C α atoms; PDE4B:PDE4D::3G45:3G4G),
90 between the two enzymes, the UCR2 domain shows following distinct residues that
91 cover the active site region: PDE4B:PDE4D::Tyr274:Phe196 (Rocque et al. 1997).
92 Burgin *et al.* have established that Tyr274 indeed provides selectivity for inhibition of
93 PDE4B. Although, other groups and we have reported selective PDE4B inhibitors, and
94 evaluated the energetics of PDE4B inhibition (Goto et al. 2014; Li et al. 2016; Sharma
95 & Wakode 2017; Xing, Akowuah, Gautam & Gaurav 2017), yet, the structural
96 dynamics of PDE4B inhibition was merely understood. Understanding the dynamics
97 of UCR2-domain guided PDE4B inhibition will guide us to design and optimize
98 available PDE4B inhibitors. Literature supports that similar MD simulation studies can
99 successfully be implemented to understand the mechanisms of molecular recognition
100 and conformational changes in therapeutic targets (Padhi, Kumar, Vasaikar, Jayaram
101 & Gomes 2012; Sharma & Wakode 2016; Moreau et al. 2017; Santos et al. 2017;
102 Douglas et al. 2018; Elfiky 2020; Islam et al. 2020; Kumar et al. 2020). In this work,
103 we performed a comparative all-atom molecular dynamics simulation study of PDE4B-
104 inhibitor complex and explored the effect of UCR2-domain residues in PDE4B
105 inhibition. In 100ns long MD simulations, we performed principal component analysis
106 (PCA), dynamical cross-correlation matrix (DCCM) analysis, secondary structure
107 analysis, and residue network mapping to shed light on the fact that the N-terminal
108 UCR2 domain improves non-polar interactions at PDE4B-inhibitor interface.
109 Therefore, these UCR2 domain residues must be targeted to optimize PDE4B
110 inhibitors (Tautermann, Seeliger & Kriegl 2015; Xiao, Yang, Xu & Vongsangnak 2015).
111

112 **2. Experimental**

113 **2.1 Data selection**

114 The highest resolution PDE4B crystal structure [PDB ID-2QYL inhibitor-NPV (4-[8-(3-
115 nitrophenyl)-1,7-naphthyridin-6-yl] benzoic acid) resolution: 1.95 Å] was retrieved
116 from the protein data(Berman et al. 2000). To study the role of the N-terminal UCR2
117 domain, we retrieved another PDE4B structure (PDB ID: 3G45, inhibitor: NPV, 8-(3-
118 nitrophenyl)-6-(pyridin-4-ylmethyl)quinoline and resolution: 2.63 Å). Here onward,
119 these complex structures will be denoted as “**U-Cat**” (structure with **U**CR2+**Cat**alytic
120 domain; PDB ID: 3G45) and “**Cat**” (structure with only **cat**alytic domain; PDB ID:
121 2QYL). To understand the role of UCR-2 residues in PDE4B-inhibitor interactions,

122 we used a common inhibitor, NPV, in both the structures and replaced the
123 coordinates of 988, a co-crystallized ligand, with NPV in the 3G45 structure.

124

125 **2.2 Protein Preparation**

126 Previously retrieved structures may have missing bond order, connectivity, steric
127 clashes or bad contacts with the neighboring residues. Therefore, both the structures
128 were prepared using Protein Preparation Wizard (Impact 6.3, Schrodinger 2014-2,
129 Maestro 9.8) (Sastry, Adzhigirey, Day, Annabhimoju & Sherman 2013) as previously
130 described (Sharma & Wakode 2016). In brief, both the structures were corrected for
131 atoms and bonds, and energy minimized to potentially relax the structures to get rid of
132 any steric clashes in the structures.

133

134 **2.3 Molecular Dynamic Simulations**

135 FF14SB force field parameters were set for the protein using the AMBER14 (Assisted
136 Model Building with Energy Refinement) LeaP module (Hornak et al. 2006). AM1-BCC
137 method was used to assign partial atomic charges for bound inhibitor (NPV), and the
138 general amber force field (GAFF) was used to create its topology (Wang, Wolf,
139 Caldwell, Kollman & Case 2004). Mg²⁺ and Zn²⁺ ions were treated according to the
140 “non-bonded” model method (Stote & Karplus 1995). The prepared systems were
141 solvated with the TIP3P water model by creating a cubic water box, where the distance
142 of the box was set to 10Å from the periphery of protein (Kiss & Baranyai 2011).
143 Molecular systems were neutralized through the AMBER LeaP module by adding the
144 necessary amount of counter ions (Na⁺) to construct the system in an electrostatically
145 preferred position.

146 The whole assembly was then saved as the prepared topology and coordinate files to
147 use as input for the PMEMD module of the AMBER (Case et al. 2005). At the first step,
148 the prepared systems were energy minimized in a two-step process: initial 1000 steps
149 of steepest descent followed by 500 steps conjugate gradient. In the first part of
150 minimization, the complex was kept fixed to allow water and ion molecules to move,
151 followed by the minimization of the whole system (water, ions and complex) in the
152 second part. The minimized systems were gradually heated from 0 to 298 K using a
153 NVT ensemble for 100ps where the protein-ligand complex was restrained with a large
154 force constant of 5 kcal/mol/Å². Following heating, the systems were equilibrated

155 under constant pressure at 298 K, and the restrain was gradually removed at NPT
156 ensemble as follows: 5 kcal/mol/Å² (40 ps), 2 kcal/mol/Å² (20 ps), 1 kcal/mol/Å² (20 ps)
157 and 0.5 kcal/mol/Å² (10 ps). Final simulations, the production run, were performed for
158 100 ns on NPT ensemble at 298 K temperature and 1 atm pressure. The step size of
159 2 fs was kept for whole simulation study. Langevin thermostat and barostat were used
160 for temperature and pressure coupling. SHAKE algorithm was applied to constrain all
161 bonds containing hydrogen atoms (Gunsteren & Berendsen 2006). The non-bonded
162 cutoff was kept on 10Å, and long-range electrostatic interactions were treated by
163 Particle Mesh Ewald method (PME) with a fast Fourier transform grid spacing of
164 approximately 0.1nm (Darden, York & Pedersen 1993). Trajectory snapshots were
165 taken at each 100ps, which were used for final analysis. The minimization and
166 equilibration were performed by the PMEMD module of AMBER14. The production
167 simulations were performed using the PMEMD program of AMBER running on NVIDIA
168 Tesla C2050 GPU work station (Gotz et al. 2012). The production run was considered
169 for the analysis which was carried out using the cpptraj module of the AMBER14 and
170 VMD (Humphrey, Dalke & Schulten 1996)

171 **2.4 RMSD**

172 The stability of the two systems during the simulations was studied by calculating
173 RMSD of the backbone atoms of different frames to the initial conformation and
174 therefore, RMSD is the measure of the average distance between the atoms (usually
175 the backbone atoms) of superimposed protein structures. RMSD of C α atoms was
176 calculated using the cpptraj analysis tool in the AMBER 14 program.

177

178 **2.5 Rg**

179 The radius of gyration is a measure of the distance between the center of mass and
180 both termini of the protein and therefore radius of gyration determines the
181 compactness of protein structure (Lobanov, Bogatyreva & Galzitskaia 2008). The
182 average Rg was computed by taking the average of C α atoms over at least 5000
183 frames of the trajectories.

184 **2.6 RMSF**

185 RMSFs were calculated with the backbone atoms of amino acid residues for both the
186 trajectories using the cpptraj module of AMBER 14. The starting conformations of each
187 complex structure were used to align the coordinates of the two trajectories.

188

189 **2.7 DCCM**

190 The cross-correlation was calculated as block average over time from 50 ns to 100 ns
191 from the MD trajectories of the two systems, U-Cat and Cat. We use the first coordinate
192 set of the analysis portion of the simulation, *i.e.*, starting structure as a reference set.
193 Each subsequent coordinate set was translated and then rotated to obtain the
194 minimum RMS deviation of the C α atoms from the reference coordinate set
195 (McCammon & Harvey 1988).

196

197 **2.8 PCA**

198 PCA was performed using the cpptraj module of AMBER 14 to understand the
199 collective atomic motion of U-Cat and Cat versions of PDE4B. Atomic coordinates
200 extracted from the last 50 ns trajectories to study the covariance matrix of the two
201 systems. The eigenvalues and the projections along the first three PCs were
202 calculated as previously described (Amir et al. 2019; Fatima et al. 2019).

203

204 **2.9 Protein secondary structure analysis**

205 In the dynamic analysis, it is imperative to identify critical changes in the secondary
206 structure element during the simulation. It imparts deep insight into the stability of the
207 secondary structure. Each secondary structure type is shown by a different color, and
208 a change in secondary structure type is easily differentiated. The secondary structure
209 information for each frame was calculated, and a two-dimensional plot was generated
210 for the last 50 ns trajectory, 500 frames.

211

212 **2.10 Residue network mapping**

213 The study of residue interacting patterns is imperative to analyze protein's structural
214 rigidity, secondary structure maintenance, and functionality. It includes crucial
215 interactions, hydrogen bond occupancies that are present during the simulation. These
216 interactions are identified using VMD. The hydrogen bond interaction was calculated
217 between the polar hydrogen atom and a nearby (< 3.4 Å) acceptor atom. Similarly, the

218 π - π interactions were calculated in the crystal structure and MD-simulated structure
219 of the last 100th ns. The π - π interactions results with the attraction of one π electron
220 cloud system with another nearby π electron cloud system. These interactions are
221 crucial in bioprocesses. In this study, we measure the inter-residue distance to each
222 hydrophobic ring centroid to identify the pair of π - π interacting residues. The residue
223 pairs within a ring centroid distance of 3.0–7.5 Å (min-max) were considered. Further,
224 we calculated the dihedral angle (θ) between the two planes that have two types of
225 structural geometries. If the dihedral angle between the planes of two rings was found
226 to be $30^\circ > \theta > 150^\circ$, the rings are in face-to-face interaction and if the angle is between
227 $30^\circ < \theta < 150^\circ$, the rings are in T-shaped (edge to face or perpendicular) interactions
228 (Anjana et al. 2012).

229

230 **3. Result and discussion**

231 The objective of our study was to understand the role of N-terminal UCR2-domain
232 residues in the stability of PDE4B-inhibitor complexes. To this end, we performed all-
233 atom molecular dynamics simulations of PDE4B-NPN complex in the presence (**U-**
234 **Cat**) and absence of the UCR2-domain residues (**Cat**). First, we confirmed the stability
235 of two systems by RMSD analysis and total energy calculations. Next, the stable MD
236 trajectories were processed to understand the dynamics of PDE4B-NPV interactions
237 through RMSF analysis, DCCM analysis, and PCA. Lastly, we analyzed residue
238 network mapping.

239

240 **3.1 Systems stability**

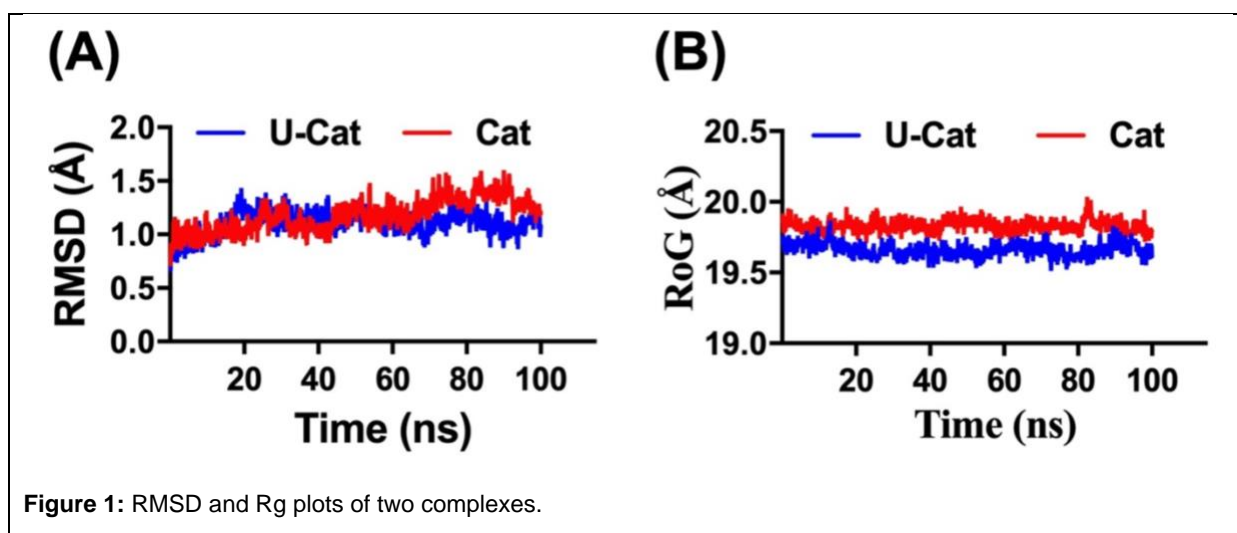

241 The reliability of our MD simulations was assessed in terms of RMSD values, total
242 energies, and radius of gyration R_g of the two simulations as follows:

243

244 **3.1.1 RMSD**

245 RMSD analysis accounts for the average distance between the selected atoms of
246 superimposed biomolecules, which indicates the closeness between the three-
247 dimensional structures. In this study, we calculated the RMSD values for the backbone
248 atoms for the proteins and all non-hydrogen atoms for the small molecule, NPV. Within
249 the initial 5-ns of each simulation, both the systems became stable and remained
250 stable throughout the 100ns long MD simulations (**Fig. 1**). During the last 50 ns long
251 simulations, the RMSD values of catalytic domain residues (Ser324-Pro665) were as

252 follows: $1.28 \pm 0.12 \text{ \AA}$ (**Cat**) and $1.11 \pm 0.09 \text{ \AA}$ (**U-Cat**). The lower magnitude of these
253 values suggests the stability of both the systems. Further, the difference between
254 these values for both the systems (**U-Cat** versus **Cat** complexes) is insignificant (t-
255 test). This finding suggests that the additional N-terminal, UCR2-domain does not
256 affect the major dynamics of the catalytic domain of the protein.

257
258 Similar to RMSD values for the catalytic domain, the RMSD values for the bound
259 inhibitor, NPV, are also low ($<1.5 \text{ \AA}$), suggesting the stable dynamics of the two
260 systems. The RMSD values for the two systems during the last 50 ns duration are as
261 follows: $1.16 \pm 0.07 \text{ \AA}$ (**Cat**) and $0.86 \pm 0.26 \text{ \AA}$ (**U-Cat**). The lower RMSD values for the
262 **U-Cat** system suggest that additional UCR2-domain stabilizes the bound inhibitor.

263

264 3.1.2 Rg

265 Rg measures the mass-weighted RMS distance of a group of atoms from their
266 common center of mass, which indicates the global dimension of the protein. For both
267 the systems (**Cat** and **U-Cat**), we calculated the Rg for the catalytic domain residues
268 (Ser324-Pro658) and observed a stable trend in Rg plot. The Rg values for the last 50
269 ns simulations for the two systems were as follows: 19.66 ± 0.05 (**U-Cat** system) and
270 19.78 ± 0.05 (**Cat** system) (**Fig. 1B**).

271

272 **3.2 Structural dynamics of PDE4B-NPN complex in the presence (U-Cat) and**
273 **absence (Cat) of UCR2-domain**

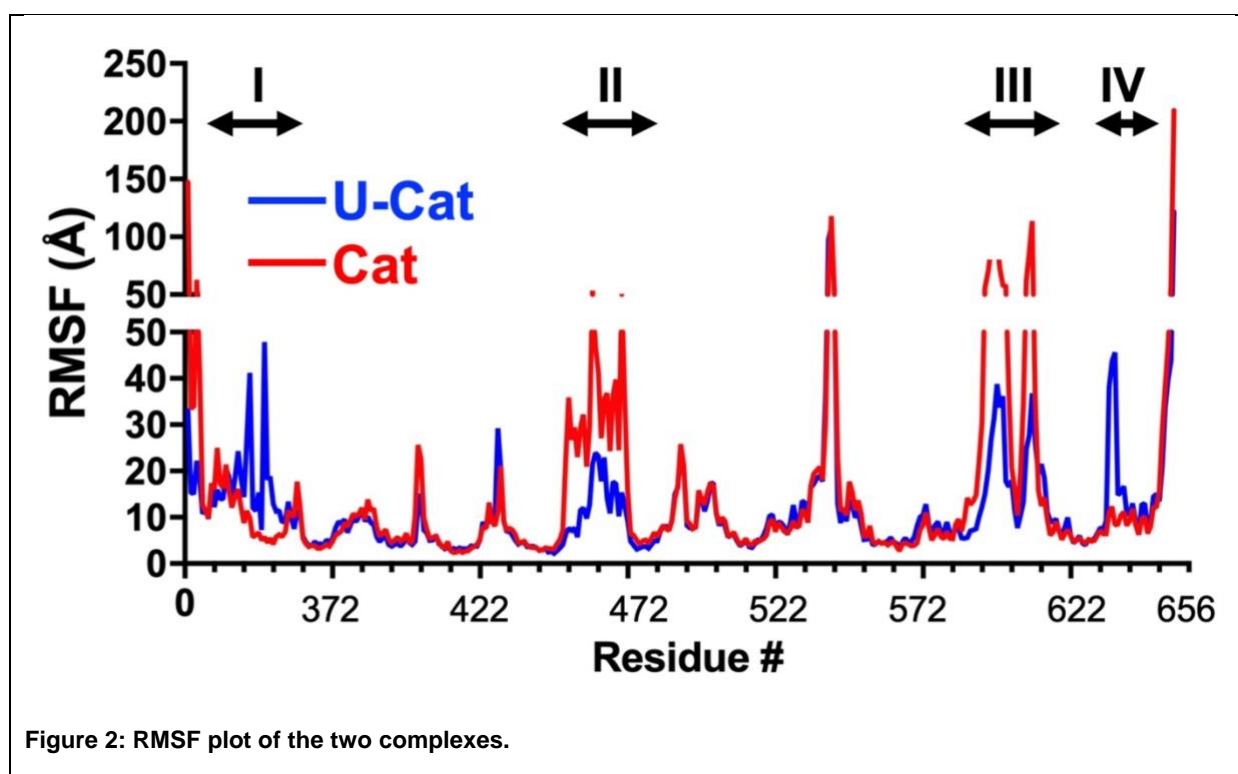

274 Once we confirmed the stability of the two systems, next we sought to study the
275 conformational changes in the two complexes (**Cat** and **U-Cat**) and performed the
276 following analyses:

277

278 3.2.1 RMSF

279 To understand and compare the dynamics of the two complexes, we calculated the
280 RMSF values for each complex. Using RMSF analysis, we studied the fluctuation at
281 the individual residue level in the two systems. To compare the two systems, we
282 rejected the additional N-terminal residues in **the U-Cat** structure and focussed on the
283 catalytic domain residues in the two complex structures. The comparative RMSF plot
284 of the two systems is shown in **Fig. 2**. A similar trend in RMSF values suggested that
285 the UCR2-domain had no drastic effect on the conformational dynamics of the two
286 systems.

287

288

289 Intriguingly, we observed the distinct behaviors of the two complexes, **U-Cat** and **Cat**,
290 in following four regions: Asp336-Asn354 (region I; 19 residues), Pro451-Glu472
291 (region II; 22 residues), Phe587-Ser614 (region III; 28 residues) and Gln635-Asp643
292 (region IV; 13 residues). Interestingly, region II residues belong to the metal-binding
293 pocket such as His450, Asn283, Glu476. The catalytic residue, Gln615, and the P

294 clamp pocket (Met583, Met603, and Val611) belong to region III. Region I and IV are
295 distant from the active site region and do not include any catalytic or functional residue.
296 Among these regions, the presence of additional UCR2-domain residues stabilized
297 the region II and III in the **U-Cat** complex, which was reflected in lower RMSF values
298 as compared to **Cat** complex. In contrast, the **region I** and **IV** showed higher RMSF
299 values for the **U-Cat** complex.

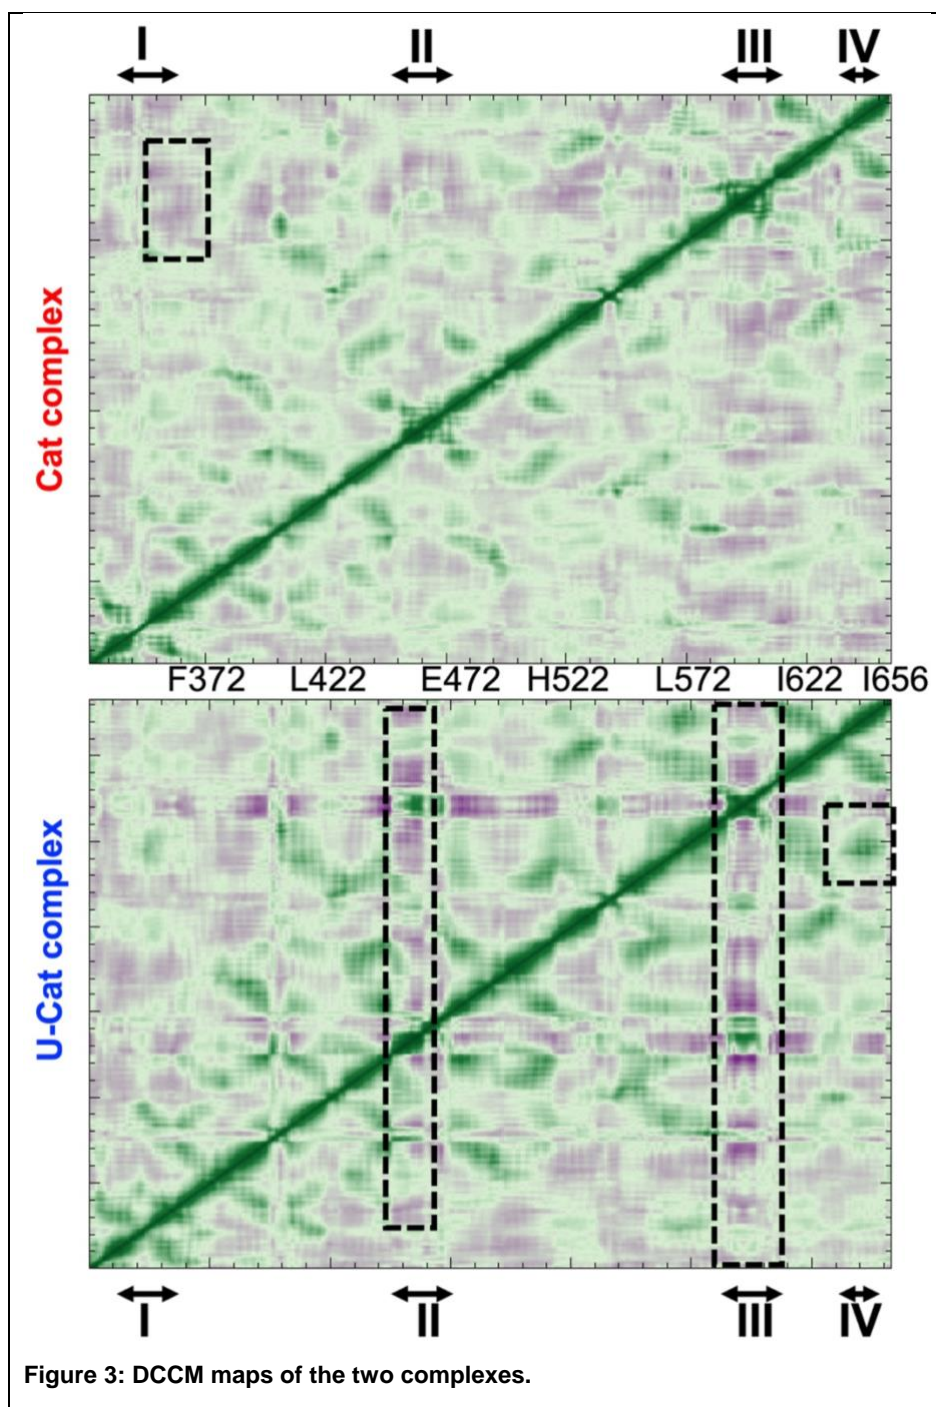

Figure 3: DCCM maps of the two complexes.

300

301 Based on the locations of these four regions to **UCR2-domain**, we hypothesized that
302 UCR2-domain might affect the associated motion of the catalytic domain of PDE4B
303 and sought to perform the dynamical cross-correlation matrix analysis.

304

305 **3.2.2 DCCM**

306 To understand the variation in the RMSF values of the two complexes and to check if
307 motions in different regions (I-IV) are related or not, we performed an inter-residue
308 DCCM analysis for C α atoms to find out the extent of correlation of atomic movements
309 (**Fig. 3**). To compare the two complex structures, **U-Cat** and **Cat**, we only considered
310 the catalytic (**Cat**) residues in the two complexes to perform the DCCM analysis.
311 Similar diagonal trends in the two figures suggested that the UCR2-domain had a
312 severe effect on the secondary structure of the two complexes suggesting that the two
313 systems, **U-Cat** and **Cat**, may have similar global dynamics. Further, the darker
314 shades of colors in the **U-Cat** complex suggested that the presence of additional
315 UCR2-domain caused a greater extent of correlative (green) and anticorrelated
316 (purple) motions in PDE4B-NPV complex. In particular, we observed intense purple
317 shades in regions II and III of the **U-Cat** complex suggesting more substantial
318 anticorrelated motions in these regions. Intriguingly, these anti-correlative motions in
319 regions II and III were correlated with low RMSF values in these regions (**Fig. 2 and**
320 **3**). On the contrary, the region I and IV showed enhanced correlative motion in the
321 presence of UCR2-domain in the **U-Cat** complex. In conclusion, the darker shades
322 plausibly suggest the enhanced associated motion U-Cat complex. Furthermore, low
323 RMSF values and enhanced anticorrelated motion in regions II and III suggest that the
324 presence of the UCR2 domain stabilizes the PDE4B-inhibitor complex through
325 enhanced anticorrelated motion (**Fig. 2 and 3**). Interestingly, these results were in line
326 with the energetics of the two systems because, in our MM-GBSA analysis, we
327 observed the U-Cat complex's enhanced stability compared to the Cat-complex
328 (**Supplementary data**).

329

330 **3.2.3 PCA**

331 Through the DCCM study, we confirmed that the presence of UCR2-domain affected
332 the correlative (and anti-correlative) motions in PDE4B-NPV complex. To understand
333 the directionality of these motions, we proceeded further and performed a PCA of the
334 two simulations (**U-Cat** and **Cat**). Here, we designated the whole average of receptor

335 motion based on C α atoms. This approach supported to figure out the overall
336 combined motion of the C α atoms in the protein denoted by the eigenvectors of the
337 covariance matrix, which is asserted by its coincident eigenvalues (Amadei, Linssen
338 & Berendsen 1993). The occurrence of the eigenvectors associated with large
339 eigenvalues can generally represent the over-all concerted motion of the protein
340 correlated to the protein function. The increasing sum of eigenvalues as a function of
341 the number of eigenvalues resulting from the MD simulation frames during 0.1 μ s is
342 shown in (**Fig. 4A**). To compare the two complexes, we ruled out additional residues
343 of UCR2-domain in **U-Cat**. We observed that the first two components of the analysis,
344 PC1, and PC2 were significantly higher for the **U-Cat** complex than the **Cat** complex,
345 suggesting that the additional UCR2-domain enhanced the directional motion at the
346 catalytic domain of PDE4B. **Fig. 4B** shows the domains, directions, and degrees of
347 motions corresponding to the first three PCs of each complex. In all three projections,
348 **the U-Cat** complex occupied a broad range of phase spaces as compared to **the Cat**
349 complex. An increase in the collective motions of **U-Cat** may plausible enhanced
350 interaction and thus the stability of the complex as compared to **Cat** complex. We next
351 studied directionality and magnitudes of the three PCs using porcupine plots. The
352 changes in direction and magnitude of **U-Cat** suggested that the additional UCR2-
353 domain posed a significant conformational impact on the overall dynamics of PDE4B.
354 We found that PC1 and PC2 motions were confined to regions Phe587-Ser610 and
355 Asp447-Asp472 in the **Cat** complex. On the contrary, the motion in the active site
356 region decreases in the **U-Cat** complex suggesting that the additional UCR2-domain
357 indeed stabilizes the catalytic cavity region in PDE4B (**Figure 4**).

358

359 To conclude, our RMSF, DCCM, and PCA results suggested that the presence of
360 UCR2-domain affected the dynamics of the catalytic domain of PDE4B. Interestingly,
361 region II and III that showed enhanced anticorrelated motions and reduced RMSF at
362 the active site region. On the contrary, the region I and IV that showed enhanced
363 correlative motion and larger RMSF values, but they were distant from the active site
364 region. Therefore, the additional domain UCR2-domain enhances the anti-correlative
365 motion at the active site cavity and thus stabilized the protein-inhibitor interactions.

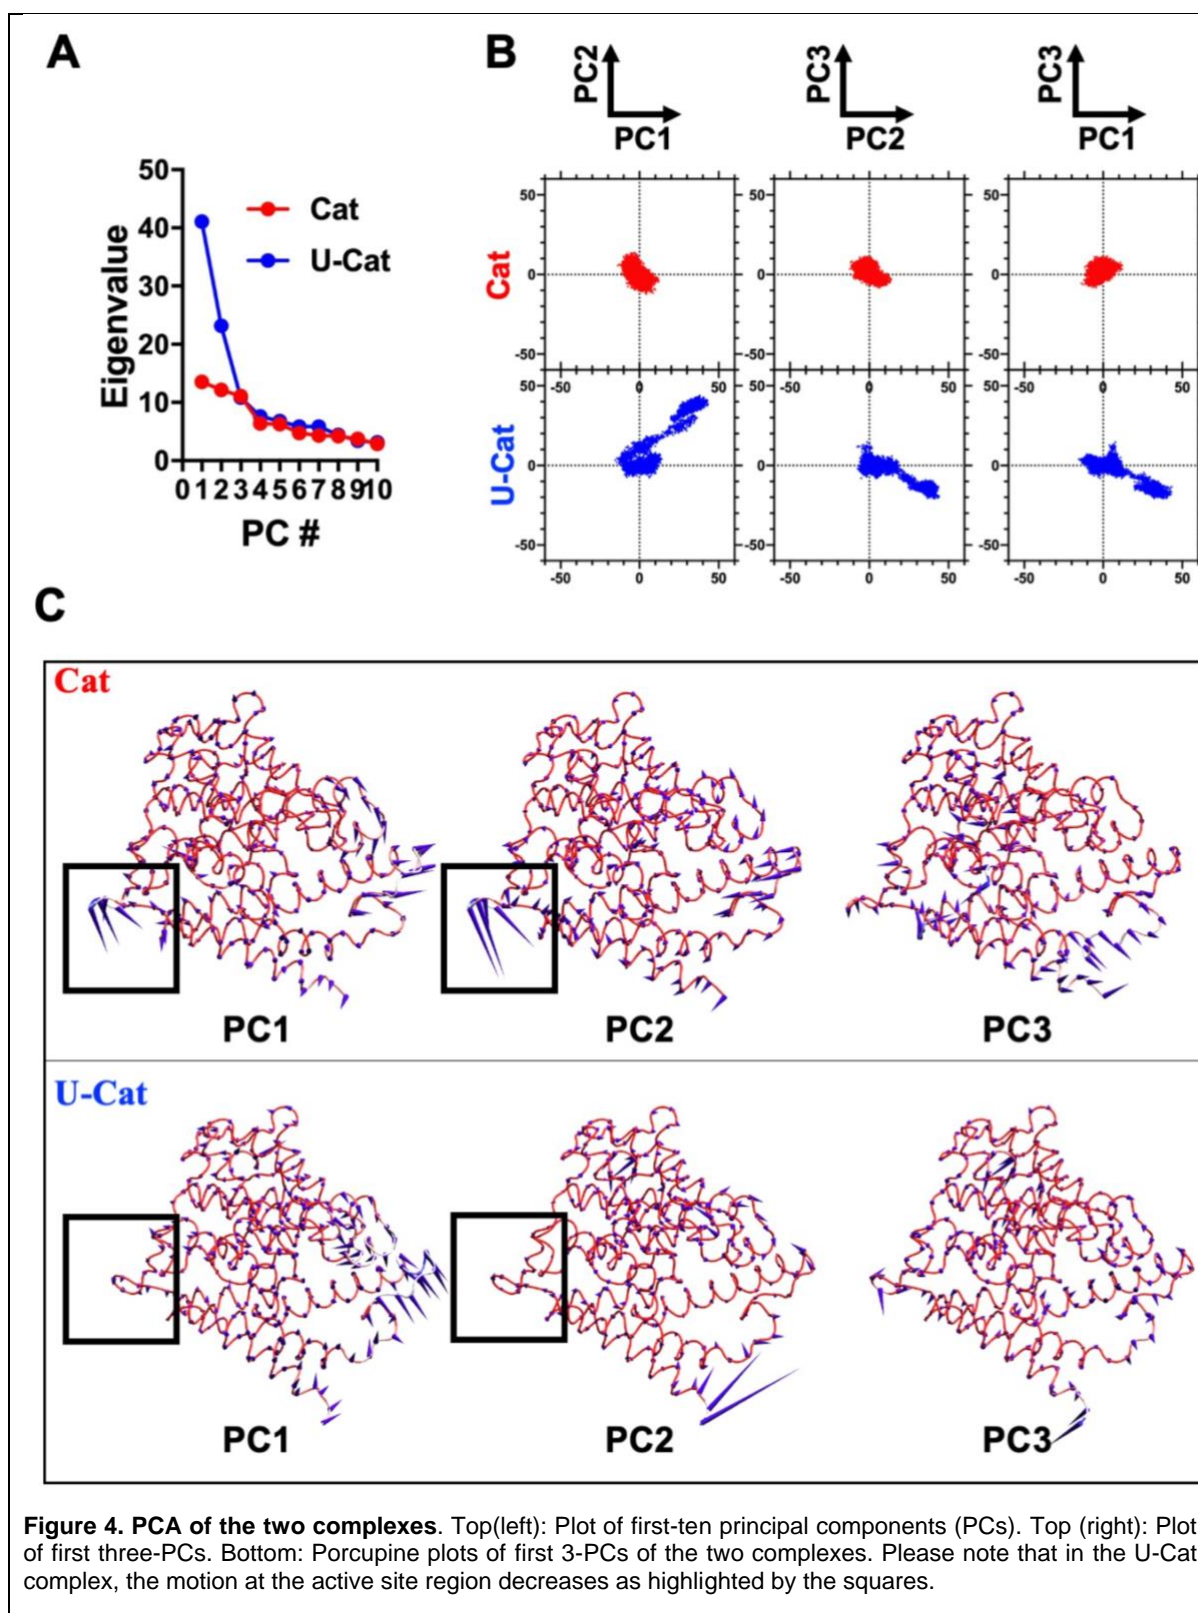

Figure 4. PCA of the two complexes. Top(left): Plot of first-ten principal components (PCs). Top (right): Plot of first three-PCs. Bottom: Porcupine plots of first 3-PCs of the two complexes. Please note that in the U-Cat complex, the motion at the active site region decreases as highlighted by the squares.

366

367 **3.2.4 Secondary structure analysis**

368 Further, to visualize critical changes in the protein conformation during the timeline

369 analysis, we performed a secondary structure analysis of the two simulations. We

370 generated a two-dimensional plot secondary structure information for the 100ns
371 trajectory (**Fig. 5**). We observed that region Ser423-Asp433, which was a turn in the
372 **U-Cat** complex, changed to a 3-turn helix in the **Cat** complex (brown to green). Further,
373 we observed a local structural transition at the region Glu343–Phe353 that was a turn
374 in the **Cat** complex but transformed into a coil in the presence of the UCR2-domain in
375 the **U-Cat** complex, shown as green to red transition in **Fig. 5**. We observed a similar
376 transition at the region Thr535-Thr550 that turned from a coil in the **Cat** complex to an
377 anti-parallel beta-sheet in **the U-Cat** complex as seen a transition from red to blue
378 color in the **Fig. 5**. Intriguingly, these differences in the secondary structure were in
379 agreement with the RMSF and DCCM analyses and thus suggested the flexible
380 residues.

381

382 **3.3 The dynamics of the active site region**

383 To further understand the effect of additional UCR2-domain on the catalytic domain of
384 PDE4B, we studied the dynamics of the active site region in detail. At first, we
385 assessed the stability of an H-bond with Gln615, an interaction reported in the crystal
386 structure. We observed a stable H-bond with Gln615 in both the simulations, **U-Cat**,
387 and **Cat** complexes. Further, we observed an enhanced occupancy of 65% of Gln615-
388 H-bond in the **U-Cat** complex compared to 43% observed in **the Cat** complex,
389 suggesting that the additional UCR2-domain indeed stabilizes the PDE4B-inhibitor
390 interactions.

391 Furthermore, we observed an additional H-bond with Tyr274 (occupancy 25%) in **the**
392 **U-Cat** complex, which was otherwise absent in the simulation of the **Cat** complex.
393 Next, we studied the dynamics of the other plausible H-bonding residues in the active
394 site cavity (Sharma & Wakode 2017). These residues include Tyr274, Tyr405, His406,
395 His410, Tyr415, Asp447, Asp564, Asn567, and Gln615. We observed that these
396 plausible H-bonding residues were more stable in the **U-Cat** complex as compared to
397 **the Cat** complex as interpreted by lower RMSD values.

398 In addition to H-bonding residues, π - π interactions with Phe618, Phe586, Tyr405, and
399 Tyr274 were stable and consistent with the interactions reported in the crystal
400 structures (**Fig. 6**). To this end, the MM-GBSA analysis also confirmed the enhanced
401 stability of the **U-Cat** complex as compared to the **Cat-complex** (**Supplementary**
402 **data**).

403

404

405

406 Altogether, our simulations and post-trajectory analyses confirm that the additional
407 UCR2-domain stabilizes the PDE4B-inhibitor complexes and therefore, must be
408 considered while evaluating the binding stability of newly designed PDE4B inhibitors.

409

410 **4. Conclusion**

411 We performed 100 ns long molecular dynamics simulations of PDE4B variants, with
412 and without the UCR2-domain. Both complexes with a common inhibitor, NPV, and
413 probed the effect of additional UCR2-domain on the stability of PDE4B-NPV
414 interactions. RMSF, DCCM, PCA, H-bond network analyses confirm that the UCR2-
415 domain enhances the correlation and anticorrelation motion in the complex structure.
416 This study provides substantial evidence to include the regulatory UCR2-domain in
417 further drug designing to evaluate the stability of newly designed PDE4B inhibitors.

418

419 **List of abbreviations**

420	PDE4B	Phosphodiesterase 4B
421	cAMP	Cyclic adenosine monophosphate
422	COPD	Chronic obstructive pulmonary disease
423	PDB	Protein data bank
424	MD	Molecular dynamics
425	RMSD	Root mean square deviation
426	RMSF	Root mean square fluctuation
427	DCCM	dynamical cross-correlation matrix DCCM
428	PCA	Principal component analysis
429	U-cat	PDE 4B structure containing UCR2, and catalytic domain
430	Cat	PDE 4B structure containing the catalytic domain

431

432 **Funding**

433 The authors are indebted to the Department of Science and Technology (DST), India,
434 for providing financial assistance to carry out this project [grant number SB/FT/CS-
435 013/2012].
