Abstract

The Duroc pig originated in the United States and is a typical lean meat pig. The breed grows fast and the body size is large, but the meat quality is poor. The Luchuan pig is one of the eight local excellent breeds in China; it has tender meat but a small size. To study the factors that determine growth, we selected the longissimus dorsi muscle of Luchuan and Duroc pigs for transcriptome sequencing. The results of transcriptome showed that 3682 genes were differentially expressed (DEGs) in the longissimus dorsi muscle of Duroc and Luchuan pigs. We screened out forty genes related to muscle development and selected the Myosin light chain-2 (MYL2) gene to perform preliminary research. Gene Ontology (GO) enrichment of biological functions and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis showed that most of the forty gene were mainly involved in the Akt/FoxO signaling pathway, Fatty acid metabolism, Arachidonic acid metabolism and Glycine, serine and threonine metabolism. Such pathways contributed to skeletal muscle growth, fatty acid metabolism and intramuscular fat deposition. These results provide insight into the mechanisms underlying the formation of skeletal muscle and provide candidate genes to improve growth traits and meat quality traits, as well as contribute to improving the growth and development traits of pigs through molecular breeding.

Keywords: Luchuan pig; Duroc pig; transcriptomics; longissimus dorsi muscles; growth and development; Myosin light chain-2 (MYL2/MLC-2)
1. Introduction

China is the largest pig breeding and pork-consuming country worldwide. The yield and quality of pork are closely related to the process of muscle development, and the content of intramuscular fat is an important index to detect the quality of pork (ZHAO et al. 2011). In recent years, research on this aspect mainly concerned the complex physiological and genetic mechanisms related to intramuscular fat (IMF) deposition, gene expression pattern and its interaction in the development process. Muscle development includes the formation of muscle fibers in the embryonic stage, development of muscle fibers in the postnatal stage and regeneration of muscle in the adult stage. This process is regulated at the transcriptional, posttranscriptional and pathway levels (LIU et al. 2012).

The Duroc pig (D), originated in the United States, is a typical lean meat-type pig. It has the advantages of fast growth, high meat yield, high feed conversion efficiency and excellent performance; however, it still has the disadvantages of poor meat quality. The Duroc pig is the main terminal male breed in the pig industry worldwide (LONERGAN et al. 2001; EDEA et al. 2017). The Luchuan pig (L) is an excellent local pig in China. It is a typical fat pig with the advantages of coarse feeding resistance, high temperature tolerance, high reproductive performance and good meat quality; however, its growth speed is slow, its fat content is high, its meat yield is low (QIONG-HUA et al. 2010; YU et al. 2017). Therefore, transcriptome sequencing of the longissimus dorsi muscle of these two breeds is of great significance to study the growth traits and meat quality of pigs.
The growth and development of muscle is a complex process, including the formation of muscle fibers in the embryonic stage, the development of muscle fibers after birth and regeneration of muscle in the adult stage. The embryonic stage mainly controls the formation of the individual muscle skeleton (PM AND J 1983). After birth, changes in different types of muscle fibers occur, such as increases in the diameter and length; at the adult stage, damaged muscle fibers are repaired (ASHMORE et al. 1973). There are four types of muscle fibers in skeletal muscle (KIM et al. 2004). The proportion of the muscle fiber type will directly affect meat quality (GUO et al. 2012). Therefore, the study of its growth and development affect meat quality. Previous reports have shown that muscle fibers can be divided into red and white fibers (KARLSSON et al. 1999). These differences in fiber components determine their different metabolic types and physiological functions, as well as affect meat quality (QUIROZ-ROTHE AND RIVERO 2004; WIMMERS et al. 2007). The content of intramuscular fat is positively correlated with the content of type I muscle fiber (SERRA et al. 1998), thus, the higher is the proportion of type I muscle fiber in skeletal muscle, the smaller is the muscle shear force and the higher is the tenderness. For example, Yorkshire pigs have a higher percentage of type I muscle fibers than Hampshire pigs. Thus, Yorkshire pork is more tender (ESSÉN-GUSTAVSSON AND FJELKNER-MODIG 1985). The proportion of type I muscle fiber in the skeletal muscle of Chinese local breeds such as the Jinhua Pig and Beijing black pig is higher than that of foreign imported breeds, and the tenderness of these local breeds is also better than that of imported breeds (CHU-RUI...
AND QING-MING 1996).

Myosin light chain-2 (MYL2/MLC-2) is a small, 167-amino acid protein of the myosin light chain family, that is a regulatory light chain (KANG AND GRIGGS 2015).

Basic light chains play an important role in the maintenance of heavy chain configuration, while regulatory light chains play a regulatory role in the activity of muscle fibers. Therefore, the proportion of four myosin light chains plays an important role in the type and growth of muscle fibers (GEEVES et al. 2005).

Upstream of the start codon of the skeletal muscle MYL2 promoter, multiple binding sites (MEF2, MyoD, and MyoG) that can promote the proliferation and differentiation of skeletal muscle cells are predicted. The MYL2 gene may have certain effects on the growth and differentiation of skeletal muscle cells (NABESHIMA et al. 1993; EDMONDSON et al. 1994). The expression level of the MYL2 gene in the skeletal muscle of Duroc and white pig was significantly higher than that in the local breed Piau, indicating that the gene is related to the growth of mammalian skeletal muscle (VERARDO et al. 2013). In conclusion, the MYL2 gene may affect early skeletal muscle differentiation and participate in the growth and development of animal skeletal muscle, and the specific molecular regulatory mechanism needs further study.

In the present study, RNA-seq technology was employed to create expression profiles of the longissimus dorsi muscle tissue from young Luchuan pigs and Duroc pigs. Subsequently, DEGs were identified and subjected to Gene Ontology (GO) and pathway analyses to reveal the changes in gene expression and regulation that may
be related to the differences in muscular development and meat quality traits between the breeds. This study mainly discusses the candidate genes that affect muscle growth, providing important regulatory information for the molecular mechanism of modern and local pork quality.
2. Materials and methods

2.1 Ethics statement and collection of tissue samples

All the animal procedures used in this study were carried out according to the Guide for Care and Use of Laboratory Animals (8th edition, released by the National Research Council, USA) and were approved by the Institutional Animal Care and Use Committee (IACUC) of Guangxi University. All the pigs in this study were sacrificed after anesthesia, and tissue samples (heart, liver, spleen, lung, kidney, longissimus dorsi and subcutaneous fat) were obtained, flash frozen in liquid nitrogen and stored at -80°C. Each variety in different developmental periods (two months and eight months) contained four pigs (two males and two females), which were provided by The Animal Husbandry Research Institute of Guangxi Zhuang Autonomous Region.

2.2 RNA extraction, library construction and Illumina sequencing

RNA degradation and contamination were monitored on 1% agarose gels. RNA purity was checked using the NanoPhotometer® spectrophotometer (IMPLEN, CA, USA). The RNA concentration was measured using the Qubit® RNA Assay Kit in a Qubit® 2.0 Fluorometer (Life Technologies, CA, USA). RNA integrity was assessed using the RNA Nano 6000 Assay Kit of the Bioanalyzer 2100 system (Agilent Technologies, CA, USA). Three micrograms of RNA per sample was used as input material for the RNA sample preparations. Sequencing libraries were generated using the NEB Next® Ultra™ RNA Library Prep Kit for Illumina® (NEB, USA).
following the manufacturer’s recommendations and index codes were added to
attribute sequences to each sample. The library preparations were sequenced on an
Illumina HiSeq platform, 125 bp/150 bp paired-end reads were generated, and the
clean reads were aligned to the reference genome using Top Hat v2.0.12. HTSeq
v0.6.1 was used to count the read numbers mapped to each gene, and then the FPKM
of each gene was calculated based on the length of the gene and read counts mapped
to this gene.

2.3 Gene Ontology and pathway enrichment analysis

Differential expression analysis of two conditions/groups (two biological
replicates per condition) was performed using the DESeq R package (1.18.0). P
values were adjusted using the Benjamini & Hochberg method. The corrected
P-value of 0.005 and log2 (fold change) of 1 were set as the thresholds for
significantly differential expression. Gene Ontology (GO) enrichment analysis of
differentially expressed genes was implemented using the GOseq R package. GO
terms with a corrected P-value < 0.05 were considered significantly enriched by
differentially expressed genes. Kyoto Encyclopedia of Genes and Genomes (KEGG)
pathway enrichment analysis of differentially expressed genes was carried out using
the KEGG seq R package. KEGG pathways with corrected P-value < 0.01 were
considered significantly enriched by differentially expressed genes.

2.4 Real–time reverse transcription–quantitative polymerase chain reaction (RT–qPCR)
Total RNA was extracted from cells or tissues with TRIzol Reagent (Thermo Fisher Scientific, America), followed by the synthesis of cDNA with reverse transcriptase and oligo-dT primers according to the manufacturer’s instructions (TaKaRa, Japan). The $2^{-\Delta\Delta C_t}$ method was used to evaluate the quantitative variation, and the GAPDH gene was used as an internal control. Diluted cDNA was amplified using gene-specific primers (Table 1) and the TB Green real-time PCR master mix (TaKaRa, Japan). RT–PCR was used to verify the accuracy of the RNA-Seq data and detect the mRNA expression of the MYL2 gene in tissues and C2C12 cells at least in triplicate with specific paired primers.

2.5 Vector construction and transient transfection

The expression vector for the MYL2 gene was generated by the nest PCR-based cloning method to improve the specificity of the PCR product. Briefly, the complete coding sequence of MYL2 was inserted into the pEGFP-N1 vector, and the recombined vector was named pEGFP-N1-MYL2. First, the longer fragment containing the complete coding sequence of MYL2 was amplified from the longissimus dorsi muscle tissue with special paired-primers and Taq enzyme (Takara, Japan), and then the complete coding sequence of the target gene was amplified with special primers with restriction enzyme cutting sites and protecting bases. The specific primer pairs for gene cloning are listed in Table 1. Next, the pMD™18-T vector, E. coli DH5α competent cells, HindIII and BamHI restriction enzymes, and T4 DNA ligase (Takara, Japan) were applied for eukaryotic vector construction. C2C12 cell were cultured in Dulbecco’s modified Eagle’s medium (DMEM) (Gibco,
Grand Island, NY, USA) containing 10% fetal bovine serum (FBS) (Thermo Fisher Scientific, America) in a 37°C incubator containing 5% CO₂. The cells were transiently transfected with ~1 μg of vector using Lipofectamine 3000 Reagent kit according to the manufacturer’s recommendations (Thermo Fisher Scientific, America) when the density became 60%–70% in a 6-well cell culture plate. The fluorescence was observed in the cells after transfection for 48 hours. Subsequently, the cells were harvested for RNA extraction, and RT–qPCR was carried out to detect the mRNA expression of relative genes.

2.6 Statistical analysis

The SPSS statistical software package for Windows, Release 11.0.1 (15 November 2001, SPSS Inc., Chicago, IL) and GraphPad Prism version 6.00 for Windows, (La Jolla, CA, USA) were used for data analyses. In each experiment, the data were presented as means ± SD. Similar results were obtained in independent experiments. A paired sample t-test was used to analyze the differences between samples. The values are denoted as significant at P< 0.05.
3. Results

3.1 Summary of RNA-seq data

Eight RNA samples were prepared from the longissimus dorsi of Luchuan and Duroc pigs. These samples were sequenced using the Illumina HiSeq™ 2000 platform. After the unqualified low-quality reads, including adaptions or heights of unknown base N, were removed from the total raw reads, approximately 551 million total clean reads (Table 2), representing 90.33% of the total raw reads, were obtained. The average clean reads Q20 and Q30 were 98.35% and 93.86% respectively. When clean reads were mapped to the Sus scrofa genome, the total mapping ratios were above 90.56%, and the average unique mapping ratio was 66.58% (Table 2). Those indexes of the RNA-seq basic data confirmed that the data were high quality and could be used for further biological analysis.

3.2 Identification of differentially expressed genes

Genes with similar expression patterns often have similar functions, or are involved in the same metabolic processes (pathways). Thus, clustering of genes with a similar expression patterns is an analytical strategy that can contribute to the identification of the function of unknown genes or can help to characterize the unknown functions of known genes. To identify clusters with functional enrichment, hierarchical clustering was performed based on gene expression patterns (Fig.1A). The gene expression profile showed small differences between two different pig breeds. The gene expression levels were calculated using the fragments per kb per
million reads (FPKM) values. Differentially expressed genes (DEGs) between sample groups were defined using the fold change values of the normalized (FPKM) expression values. DEGs were filtered with $|\log_2 \text{Fold Change}| > 1$ and corrected q-value (padj) < 0.001. Compared with the Duroc pig, 3,682 DEGs comprised 2,399 upregulated DEGs and 1,283 downregulated DEGs were identified in the Luchuan pig (Fig. 1B).

3.3 GO enrichment and KEGG pathway analyses

To further determine the functions of the DEGs, functional categorization of all the DEGs was performed using GO annotation. The annotated results were classified into three parts: biological process, cellular component and molecular function (Fig. 2A). The top 5 of each part were shown as follows: (1) biological process: (i) cellular process; (ii) metabolic process; (iii) biological regulation; (iv) regulation of biological process; (v) response to stimulus; (2) cellular component: (i) cell; (ii) cell part; (iii) organelle; (iv) membrane; (v) organelle part; (3) molecular function: (i) binding; (ii) catalytic activity; (iii) molecular function regulator; (iv) signal transducer activity; (v) molecular transducer activity.

KEGG analysis of DEGs was also performed. As shown in Fig. 2B, the pathways were classified into six groups by function: cellular processes, environmental information processing, genetic information processing, human diseases, metabolism and organismal systems. At the same time, the pathways were also sorted by the correlativity of enrichment (Fig. 2C). We obtained 63 pathways ($p < 0.05$), among which the top 30 pathways are shown in Table 3. Combined the
analysis results of GO enrichment and KEGG pathway and previous studies, we chose differentially expressed genes (Table 4) as candidate genes for further study that were associated with the biological processes of muscle tissue development, muscle cell differentiation, skeletal muscle tissue regeneration, fatty acid oxidation and lipid metabolism.

3.4 Verification of the accuracy of the RNA-Seq data using RT–qPCR

Eight candidate genes involved in muscle and fat were randomly selected to validate the accuracy of the RNA-Seq data by RT–qPCR (Fig.3). The expression patterns of these 7 genes were consistent with the RNA-Seq data. These results suggest that the RNA-Seq data are credible and can be used for subsequent experiments. This finding suggests that the identified DEGs play major roles in affecting the meat quality and growth rate of Duroc and Luchuan pigs.

3.5 Analysis of the MYL2 gene expression pattern

Most of the functional genes have tissue-specific expression, so we detected the mRNA expression of the MYL2 gene in different tissues of pigs. The expression of the MYL2 gene in different tissues of 2-month-old Luchuan pigs (Fig. 4A) and Duroc (Fig. 4B) pigs was similar. Functional genes are in a dynamic condition in the same tissue during different developmental and growing periods. The MYL2 gene expression level in the longissimus dorsi of Luchuan and Duroc pigs was significantly higher at 2 months than at 8 months (p< 0.05) (Fig.4C). The expression level of the MYL2 gene in the longissimus dorsi of Luchuan and Duroc pigs at 2 and
8 months of age was detected, respectively, by RT–qPCR. The results showed that the MYL2 gene expression level in the Luchuan pig was significantly higher than that in the Duroc pig in both periods (p< 0.05) (Fig.4D). The cause may be related to the difference of growth speed and muscle fiber type of different pigs in different growth stages.

3.6 Expression trend of the MYL2 gene and genes related to muscle development in C2C12 cells

The MYL2 gene may be related to muscle development. We screened some downstream genes (MYH1, MYH2, MYH4, MYH7, MYOD, MEF2c and MSTN) of MYL2 and detected their expression in C2C12 cells. Next, we tested whether MYL2 could change the gene expression in C2C12 cells by transfecting the overexpression vector MYL2. Fluorescence could be observed in C2C12 cells transfected with the pEGFP-N1-MYL2 recombined plasmid and empty vector pEGFP-N1 but not in the negative control group (Fig. 5A). We found that the expression of MYH1, MYH2, MYH4, MYH7, MyoD and MEF2c was increased significantly and the expression of MSTN was decreased significantly when the expression of the MYL2 gene was increased in C2C12 cells (p< 0.05) (Fig. 5B).
4. Discussion

Differences exist in the muscle growth and meat quality between Chinese and Western pig breeds, but the molecular mechanism remains unclear. RNA-seq is an effective method to identify new genes and their potential functional characteristics. Differences in the gene expression profiles can unveil mechanisms underlying the biological activities of various genes. Previous studies have shown that some changes in muscle fiber type characteristics and metabolic potential can explain changes in meat quality (CHANG et al. 2003).

In this study, the mRNA abundance of the longissimus dorsi of Luchuan and Duroc pigs was studied to explain the difference at the molecular level and preliminarily verified the selected MYL2 gene. The RT–qPCR results showed that MYL2 gene expression in the longissimus dorsi of Luchuan and Duroc pigs was significantly higher at 2 months than at 8 months. The MYL2 gene expression in the longissimus dorsi of two month old, six month old, eight month old and ten month old black cattle decreased gradually (LIU et al. 2018), a finding that is similar to the results of this study. The MYL2 gene may affect the early differentiation of skeletal muscle and participate in the growth and development of skeletal muscle. The number of muscle fibers is stable before birth, and muscle growth is only the result of fiber elongation and thickening. Studies have shown that MYL2 is involved in the production of prenatal muscle fibers and the expression of genes in the skeletal muscle of Duroc and Large White pigs was significantly higher than that of Piau (ZHANG et al. 2009; LL et al. 2013). Our results showed that the MYL2 gene
expression in Luchuan pigs was significantly higher than that in Duroc pigs at 2 and 8 months of age. The cause may be related to the different times at which the maximum growth speed of different pigs appears. Studies have shown that the maximum growth rate of Duroc pigs is 130–150 days (MAO-ZHONG AND XIAO-WEI 1996; LIU et al. 2012) while that of Luchuan pigs is 30–60 days (QIONG-HUA 1963).

The composition of skeletal muscle fiber types directly affects muscle quality. The content of intramuscular fat is positively related to the content of type I muscle fiber (SERRA et al. 1998). The higher is the proportion of type I muscle fiber in skeletal muscle, the smaller is the shear force of muscle, and the higher is the tenderness. The proportion of type I muscle fiber in the skeletal muscle of the Jinhua Pig and Beijing black pig in China is higher than that of "Du × Chang × Da" and other introduced breeds, and the tenderness of these local breeds is also better than that of the introduced breeds (CHU-RUI AND QING-MING 1996). Studies have shown that the MYL2 gene regulates the activity of fast muscle fiber and transforms the type of muscle fiber (PARK et al. 2011). Additionally, the quality of the Luchuan pig is better than that of the Duroc pig, possibly explaining why MYL2 gene expression in the longissimus dorsi of 8-month-old Luchuan pigs is significantly higher than that of 8-month-old Duroc pigs. In conclusion, the MYL2 gene may be involved in the formation of skeletal muscle, early differentiation of skeletal muscle and transformation of muscle fiber types.

The MYL2 promoter is a skeletal muscle-specific promoter. Multiple binding sites (MEF2, MyoD and MyoG) that can promote the proliferation and
differentiation of skeletal muscle cells are predicted upstream of the initiation
codon(NABESHIMA et al. 1993; EDMONDSON et al. 1994). The MYL2 gene may be
involved in the regulation of the growth and differentiation of skeletal muscle cells.
MYL2,MYH1,MYH2,MYH4 and MYH7 could be grouped into networks of
functional elevate for muscularity(LL et al. 2013). These include myofibril,
muscle system process, structural constituent of muscle, motor activity and Wnt
signaling pathway. MyHCI, Ila, Ilb and Ilx are expressed in pig skeletal muscle, and
the pig muscle fibers are divided into four types according to the myosin heavy
chain (MyHC) subtype unique to muscle fibers: I, Ila, Ilx and Ilb (MYH7, MYH2,
MYH1 and MYH4 gene coding) type(CHANG AND FERNANDES 1997). MEF2
transcription factors are major regulators of muscle differentiation and have been
recently involved in activity-dependent muscle fiber type remodeling. There are four
MEF2 genes (MEF2a, -2b, -2c, and -2d), and further variants are generated by
alternative splicing(BLACK 1998). A role of MEF2 genes in the regulation of the
fiber type profile in vivo is supported by the finding that the proportion of type I
fibers is decreased in mice with muscle-specific knockout of MEF2c or MEF2d, but
not MEF2a, and is increased by the overexpression of an activated MEF2c
(MEF2c-VP16)(POTTHOFF et al. 2007). Additionally, MEF2 can bind to the CIS
factors in the promoter region of the myofibrillar gene (MYH1, MYH2, and MYH4)
and affect its transcription efficiency to regulate the composition of myofibrillar
types(ALLEN et al. 2005). MyoD is a dominant regulatory gene in the embryonic
muscle development of vertebrates that plays an important role in the formation and
differentiation of skeletal muscle (Lee et al. 2004). MyoD can activate the transcription of muscle genes through multiple channels, thus promoting the differentiation of myoblasts. Compared with other myogenic regulators, MyoD mainly plays a role in the process of myogenesis, and its expression plays an important role in maintaining the differentiation of myocytes. The loss of MyoD can cause the proliferation and differentiation of myoblasts to fail (Alves et al. 2003; Fulco et al. 2003). Myostatin (MSTN) is a secreted growth factor that is mainly expressed in skeletal muscle and can inhibit muscle growth (Lee 2004). In recent years, many candidate genes related to muscle growth and meat quality traits have been found in domestic and foreign studies (Knapp and J. 2006; Hoashi et al. 2008). MSTN and MyoG are considered the main candidate genes related to muscle growth and development in animals (Koohmaraie 1996; Knapp and J. 2006). We overexpressed the MYL2 gene in C2C12 cells and found that the expression levels of MYH1, MYH2, MYH4, MYH7, MyoD and MEF2c genes increased significantly with the significant increase in the MYL2 gene expression, and MSTN decreased significantly. Therefore, the MYL2 gene may be involved in the regulation of muscle formation and development, as well as the transformation of muscle fiber types, affecting the growth and development of livestock.
5. Conclusion

In this study, transcriptomic analyses of the longissimus dorsi muscle tissues of two month old Duroc pigs and Luchuan pigs were performed using RNA-seq. Presently, the DEGs study enabled the determination of the biological functions and pathways related to the observed variety specific differences in muscle development and some differentially expressed genes, particularly MYL2, MYH1, MYH2, MYH4, MYH7, MYOD, MEF2c and MSTN. These genes may play a role in the growth and differentiation of skeletal muscle cells and the transformation of muscle fiber types through some interaction networks. We have made a preliminary hypothesis about the role of the MYL2 gene, and its regulatory mechanism needs further study. This study will help to better understand muscle growth and structure and their effects on meat development.

</table>

Note: "this primer pair is used in the amplification of the complete coding sequence of the MYL2 gene for vector construction, the letters with single underline represent restriction enzyme cutting sites, and the letters with double underline represent protecting bases. The primers marked ‘Sus’ and
‘Mus’ were used for mRNA expression in pig tissues and C2C12 cells by real-time quantitative RT–PCR (RT–qPCR)
