Running head: Temperature alters mosquito immune gene expression

Keywords: *Aedes aegypti*, transcriptome, temperature, chikungunya virus, immune genes, immunity, gene ontology, pathway enrichment

1 ABSTRACT

2 Arthropod-borne viruses (arboviruses) such as dengue, Zika and chikungunya constitute a
3 significant proportion of the global disease burden. The principal vector of these pathogens
4 is the mosquito *Aedes (Ae.) aegypti*, and its ability to transmit virus to a human host is
5 influenced by environmental factors such as temperature. However, exactly how ambient
6 temperature influences virus replication within mosquitoes remains poorly elucidated,
7 particularly at the molecular level. Here, we use chikungunya virus (CHIKV) as a model to
8 understand how the host mosquito transcriptome responds to arbovirus infection under
9 different ambient temperatures. We exposed CHIKV-infected mosquitoes to 18 °C, 28 °C and
10 32 °C, and found higher temperature correlated with higher virus replication levels,
11 particularly at early time points post-infection. Lower ambient temperatures resulted in
12 reduced virus replication levels. Using RNAseq, we found that temperature significantly
13 altered gene expression levels in mosquitoes, particularly components of the immune
14 response. The highest number of significantly differentially expressed genes in response to
15 CHIKV was observed at 28 °C, with a markedly more muted effect observed at either lower
16 (18 °C) or higher (32 °C) temperatures. At the higher temperature, the expression of many
17 classical immune genes, including *Dicer-2* in the RNAi pathway, was not substantially
18 altered in response to CHIKV. Upregulation of Toll, IMD and JAK-STAT pathways was
19 only observed at 28 °C. Time post infection also led to substantially different gene expression
20 profiles, and this effect varied depending upon the which temperature mosquitoes were
21 exposed to. Taken together, our data indicate temperature significantly modulates mosquito
22 gene expression in response to infection, potentially leading to impairment of immune
23 defences at higher ambient temperatures.

24 INTRODUCTION

25 Arthropod-borne diseases constitute a significant proportion of the global infectious disease
26 burden, with yearly estimates of ~ 1 billion infections and 1 million deaths [1]. Dengue viruses
27 (DENVs 1-4), Zika virus (ZIKV) and chikungunya (CHIKV) are some of the most common
28 pathogens causing epidemics of arthropod-borne virus (arboviruses) disease in recent decades
29 [2]. These viruses are principally vectored to humans by the mosquitoes *Aedes (Ae.) aegypti*
30 and *Ae. albopictus* [3]. Because mosquitoes are poikilothermic, almost all their biological
31 activities are influenced by ambient environmental conditions [4], such as temperature.
32 Understanding how mosquitoes respond to changes in this key parameter, over the short and
33 long term, are necessary to improve predictions of arbovirus futures.

34 Recent projections have suggested that climate change may increase the risk of arbovirus
35 transmission, as higher average temperatures are projected to expand the geographic
36 distributions and lengthen active seasons of arthropod vectors [5-9] Temperature is also known
37 to alter the ability of *Aedes* spp. mosquitoes to transmit viruses, with higher temperatures
38 following infection leading to increased viral replication and earlier transmission potential [10,
39 11]. Conversely, lower ambient temperatures lead to decreased viral replication and delayed
40 transmission by mosquitoes [12, 13]. Exactly how ambient temperature influences the
41 physiological, molecular and genetic interactions between virus and mosquito during infection
42 remains poorly elucidated.

43 Mosquitoes possess physical and physiological barriers against pathogen infection. Insect
44 protection relies on the humoral and cellular immune responses, which comprise the innate
45 immune system [14]. Mosquito immune response can be divided into four components:
46 pathogen recognition, activation of immune signalling, immune effector mechanisms [15] and
47 immune modulation by the regulation of mosquito homeostasis. Apart from known (termed
48 ‘classical’) immune genes within these four categories, recent studies have indicated the

49 involvement of additional gene families during arbovirus infection in *Ae. aegypti*. Additional
50 genes included cytoskeleton and cellular trafficking, heat shock response, cytochrome P450,
51 cell proliferation, chitin and small RNAs [15]. Long noncoding RNAs (lncRNAs) are also
52 involved in *Ae. aegypti*-virus interactions, particularly in DENV and ZIKV infections [16, 17].
53 However, it is not well understood how gene expression is modulated in mosquitoes exposed
54 to different ambient temperatures. Even less well understood is how the mosquito immune
55 response may change in response to temperature during prolonged virus infection, and how
56 this may impact on the insect's ability to vector pathogens.

57 CHIKV is an emerging arbovirus, responsible for several recent large outbreaks globally with
58 an estimated 10 million cases [18-20]. Rarely fatal, CHIKV typically causes an acute febrile
59 syndrome and severe, debilitating rheumatic disorders in humans that may persist for months
60 [21]. The main vector of CHIKV is *Ae. aegypti* [22], with *Ae. albopictus* also playing an
61 important role in more recent outbreaks [23]. CHIKV cases were reported from Africa, Asia,
62 Europe, islands of Indian and Pacific oceans until 2013, when the first autochthonous cases
63 were reported in the Americas on islands in the Caribbean. By the end of 2017, more than 2.6
64 million suspected cases of CHIKV had been reported from the Caribbean and the Americas
65 [24]. Since then, the virus has continued to circulate and cause sporadic disease and periodic
66 outbreaks with very high attack rates in many areas of the world [24]. CHIKV is a single-
67 stranded, positive sense RNA virus from the *Togaviridae* family, genus *Alphavirus*. To date,
68 the interactions between emerging alphaviruses, such as CHIKV, and their mosquito hosts
69 under different temperatures have been less characterised than those of flaviviruses, namely
70 DENV and ZIKV. In addition, although mosquitoes remain infected with arboviruses for life
71 [25], the immune responses underlying long term persistence of these pathogens is not well
72 understood.

73 Here, we report how exposure to 3 ambient temperature regimes (18 °C, 28 °C and 32 °C) alter
74 gene expression in mosquitoes infected with CHIKV, sampled at two time points post infection.
75 We found that temperature alters the transcriptome, with the highest number of upregulated
76 genes observed at 28 °C, while lower temperatures were associated with more downregulated
77 genes. Importantly, we observed the absence of *Dicer-2* and low levels of immune gene
78 expression at 32 °C, suggesting heat may impair mosquito immunity and the ability to mount
79 an adequate RNAi response. We also show that mosquito gene expression is not constant over
80 the course of arbovirus infection, with distinct gene expression profiles observed for each
81 temperature and time point sampled.

82

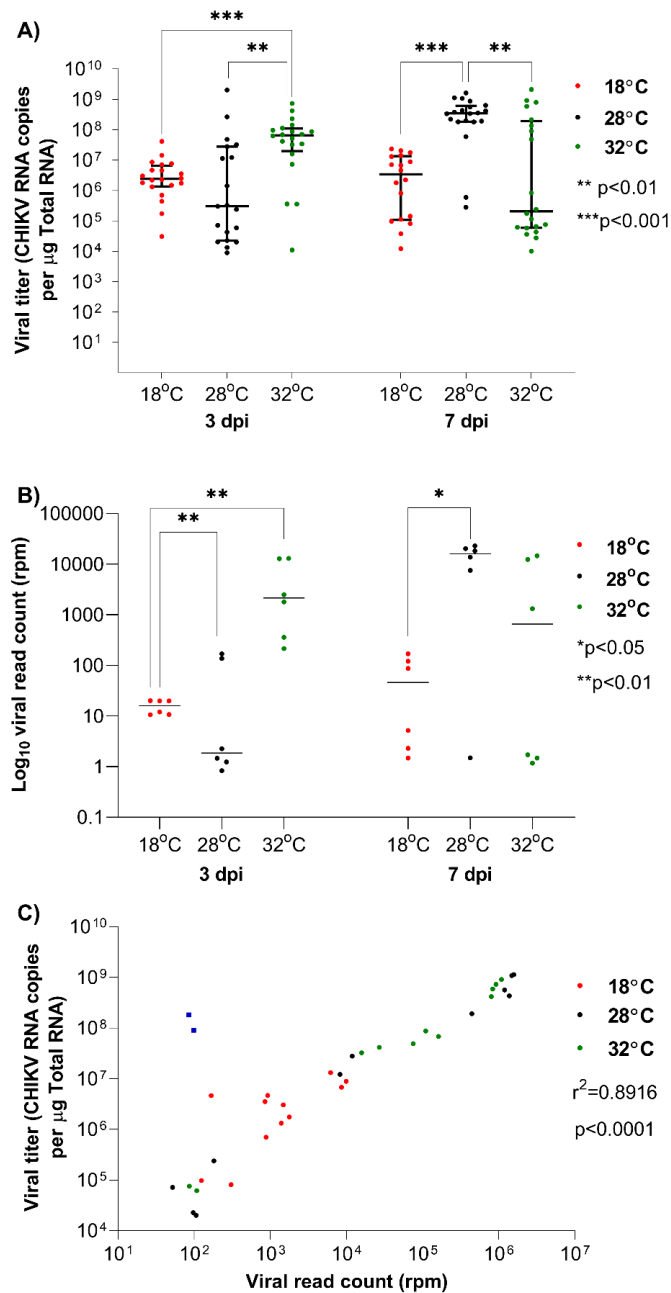

83 **RESULTS**

84 **CHIKV replication varies with ambient temperature and age of mosquitoes**

85 To determine how ambient temperature modulates replication of CHIKV, and how this may
86 vary over the course of infection, *Ae. aegypti* mosquitoes were orally infected with a CHIKV
87 strain from the Asian genotype (GenBank accession MF773560) and held at 18, 28 or 32 °C
88 for either 3- or 7-days post infection (dpi) (n=18-20 mosquitoes per combination of T °C and
89 dpi). Using qRT-PCR (as per [26]), we found that at 3 dpi, the number of virus genome copies
90 in mosquito bodies (including heads but without wings and legs) held at 32 °C was significantly
91 higher than that from mosquitoes held at the other temperatures (**Fig. 1 A**). By contrast, at 7
92 dpi, the highest amount of virus was present in mosquitoes held at 28 °C, with a decline in
93 CHIKV copy number observed at 32 °C (**Fig. 1 B**). Next, we performed RNAseq on a subset
94 of six mosquitoes for each temperature and timepoint (n=72 total). Of the 2,661,279,246
95 Illumina paired end reads generated in this study, 10,155,660 (0.38%) of reads mapped onto
96 the CHIKV genome (MF773560 strain). CHIKV reads obtained from the RNAseq data were

97 largely congruent with qRT-PCR results (**Fig. 1 C**), with the highest read count (normalized
98 reads per million) observed in mosquitoes held at 32 °C and sampled at 3 dpi. Normalized viral
99 read counts were significantly correlated with copy number from qRT-PCR ($r^2=0.8916$,
100 $p<0.001$). Two samples, from a total of 72 submitted for RNAseq, were removed from
101 downstream analyses of differential gene expression. These samples were identified as outliers
102 in the correlation between virus titer and normalised read counts (**Fig. 1 C**).

103

104

105 **Fig. 1. Effect of temperature and day post infection (dpi) on CHIKV replication in *Ae. aegypti***

106 **mosquitoes. A)** CHIKV RNA copy numbers detected using qRT-PCR in whole mosquito bodies, 18

107 °C (n=20 and n=18), 28 °C (n=19 and n=20) and 32 °C (n=20 in each timepoint), sampled at 3 and 7

108 dpi. Statistical significance was assessed using Mann Whitney tests. **B)** CHIKV read counts obtained

109 from RNAseq of *Ae. aegypti* samples (6 mosquito bodies per each temperature/dpi combination).

110 Log₁₀ normalised reads per million (rpm) counts shown. **C)** Pearson correlation between body

111 CHIKV titer from qRT-PCR and virus read counts, across all temperatures and both time points. Each

112 point on the plots represents an individual mosquito. The dark blue squares in C) indicate two outlier

113 samples that were removed from downstream analyses of the mosquito transcriptome.

114 Temperature alters differential gene expression during CHIKV infection

115 A total of 2,511,065,774 (94.36%) reads from 70 samples were mapped to the reference
116 genome of *Ae. aegypti*, version AaegL5.2 (**Supplementary Table 1**). For each temperature
117 and time regime, differentially expressed genes (DEGs) in response to CHIKV infection were
118 identified using DESeq2 by comparison to uninfected control mosquitoes. DEGs were
119 considered statistically significant if the adjusted p-value <0.05 and absolute fold change (FC)
120 > ± 1.5 . At 3 dpi, we detected 715 DEGs across all temperature regimes. We observed a large
121 number of upregulated genes (n=374) in mosquitoes held at 28 °C, but a dramatically lower
122 number at 32 °C, with classical immune gene expression generally following the same pattern
123 (**Fig 2 A**; **Supplementary Table 2** for a list of genes). At 7 dpi, we found a similar number of
124 DEGs (n=726) in response to CHIKV infection to that observed at 3 dpi (**Fig 2 B**). The highest
125 number of DEGs was observed in mosquitoes held at 28 °C, including classical immune
126 response genes, a pattern similar to 3 dpi (**Supplementary Table 3**). By contrast, at 7 dpi we
127 observed a substantial decrease in DEGs at 18 °C but a marked increase in upregulated DEGs
128 at 32 °C.

129
130 **Fig 2.** Differentially expressed genes (DEGs) in response to CHIKV infection in *Ae. aegypti*.
131 Mosquitoes were held at 3 ambient temperatures and sampled at **A)** 3 dpi and **B)** 7 dpi. DEGs were
132 identified using DESeq2, with a Fold Change (FC) > ± 1.5 and adjusted p-value < 0.05. The number
133 of DEGs involved in the classical immune response is shown in yellow.

134 Across all temperatures and time points, the top 10 upregulated (in terms of fold-change) DEGs
135 were predominantly genes known to be involved in thermoregulatory responses, such as heat
136 shock proteins (particularly *hsp70*) and lethal (2) essential for life protein (*l2efl*) (**Table 1**). By
137 contrast, the top 10 downregulated DEGs were more heterogeneous across all temperatures and
138 both time points. At 3 dpi, proteolysis, intracellular signal transduction, protein-binding and
139 oxidation-reduction process related genes were among the top 10 downregulated genes at 18
140 °C. At 28 °C, downregulated genes were predominantly involved in oxidation-reduction, cell
141 division, zinc ion binding, nucleic acid binding and integral component of membrane (**Table**
142 **1**). Four genes downregulated at 32 °C were related to oxidation-reduction and protein binding.
143 At 7 dpi, RNA binding, pigment binding, lipid binding and transport, proteolysis and integral
144 component of membrane gene were among the top 10 downregulated genes at 18 °C (**Table**
145 **1**). Microtubule binding, catalytic activity, odorant binding, membrane and ionotropic
146 glutamate receptor activity genes were among the most downregulated DEGs at 28 °C, while
147 odorant binding, nucleotide binding, ATP binding, phototransduction and transferase genes
148 were downregulated at 32 °C. Across all temperature regimes and dpi, we observed 11
149 lncRNAs being among the top 10 downregulated, but no lncRNAs were present among the top
150 10 upregulated genes (**Table 1**). At 3 dpi, 14 genes were upregulated under all three
151 temperature regimes in response to CHIKV infection, and comprised 10 HSPs, nucleic acid
152 binding and genes involved in regulation of cell cycle (**Table 2**). By 7 dpi, 22 genes that were
153 upregulated across all temperature regimes (**Table 2**) with a similar pattern observed in the
154 categories of genes involved. There were no downregulated DEGs in common across the three
155 temperatures, for either time points. Overall, the results indicate similar categories of
156 upregulated genes, but far greater heterogeneity of downregulated DEGs, among the
157 temperature regimes in response to CHIKV infection.

158 **Table 1.** Top 10 differentially expressed genes (DEGs) ranked by fold change in CHIKV-infected *Ae. aegypti* versus uninfected controls, held at three
 159 different temperatures (T°C) and sampled at two time points post infection (dpi).

164

165 **Identification of *Ae. aegypti* genes involved in classical and non-classical immune**
 166 **response and updating annotations of AegL5.2**

167 To determine how the expression of known mosquito immune genes changes with temperature
 168 in response to CHIKV infection, we first identified from ImmunoDB database 445 genes listed
 169 under 27 families that were similarly annotated in AegL1 and AegL5.2. This indicated that
 170 166 genes were no longer available with the same gene ID in the latest genome annotation

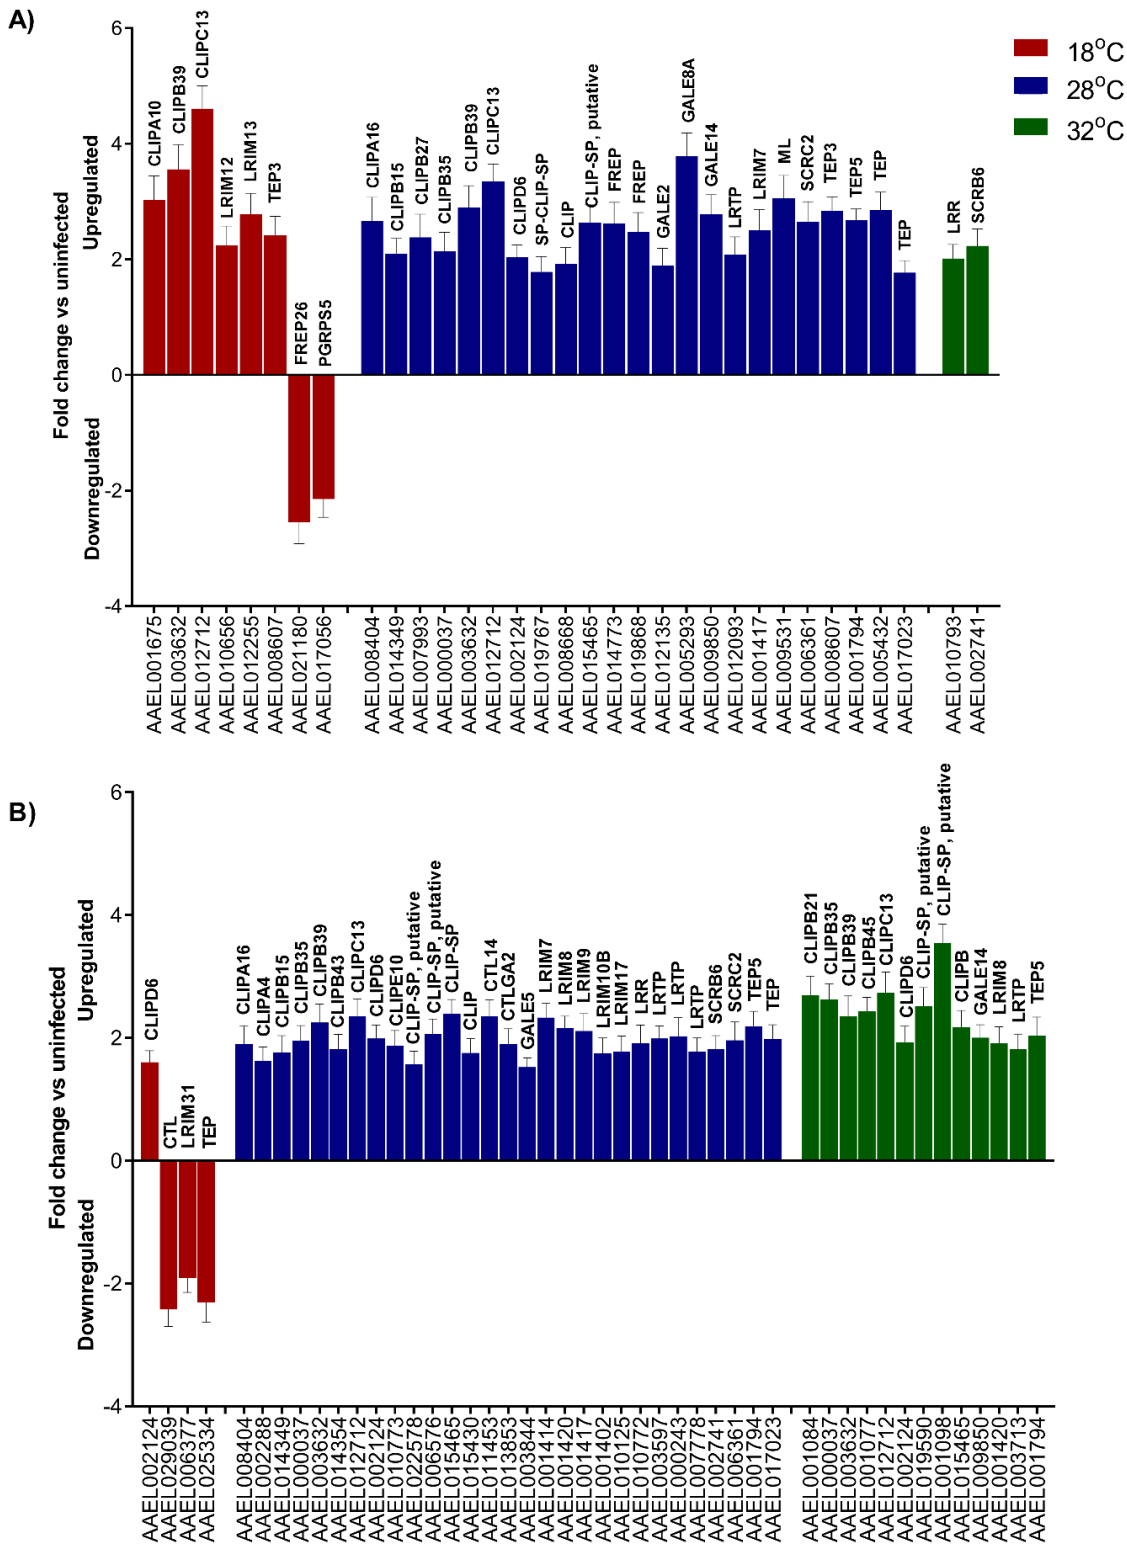

171 release AaegL5.2. Since the release of AaegL1, a number of additional genes have been
172 identified to be involved in mosquito immune response. Using a literature review, we identified
173 10 additional gene families, resulting in a total of 37 gene families implicated in mosquito
174 immunity (**Supplementary Table 4**), producing a final list of 998 genes. The list was divided
175 into classical or non-classical components (**Supplementary Tables 5 and 6**) [4, 27-34]. Genes
176 already identified and directly involved in humoral and cellular immune response were
177 considered as classical immune genes [35]. Genes outside of these classical immune pathways
178 that are transcriptionally altered in response to arboviral infections in *Ae. aegypti* were
179 considered as non-classical immune genes [36]. We next considered DEG patterns in classical
180 immune genes, categorised under the four main processes of immune response: pathogen
181 recognition, immune signalling, pathogen destruction and immune gene modulation.

182

183 **Pathogen recognition receptor (PRR) genes**

184 At both time points sampled post CHIKV infection, the majority of PRR DEGs were observed
185 in mosquitoes held at 28 °C (n DEGs=24; **Fig. 3**), with only a handful detected at the other
186 temperatures. The number of PRR DEGs observed at 28 °C stayed largely similar at both time
187 points (3 dpi n=24; 7 dpi n=30). Strikingly, only two PRRs were found to be differentially
188 expressed at 32 °C at 3 dpi (**Fig. 3A**), although by 7 dpi that number had increased 6-fold (**Fig.**
189 **3B**). By contrast, the number of PRRs differentially expressed at 18 °C (n=8) was halved by 7
190 dpi. PRR DEGs were predominantly CLIP domain serine proteases, leucine-rich immune
191 receptors (LRIM) and leucine-rich repeat-containing proteins (LRR), galectins, fibrinogen
192 related proteins (FREP), ML/Niemann-pick receptors, peptidoglycan recognition proteins
193 (PGRP), scavenger receptors (SCR), and thioester proteins (TEP). At 3 dpi, two CLIPs
194 (AAEL003632: *CLIPB39*, AAEL012712: *CLIPC13*) and one TEP (AAEL008607: *TEP3*) were

195 found in common to mosquitoes held at 18 °C and at 28 °C. At 7 dpi, we observed *CLIPD6*
196 (AAEL002124) to be upregulated under all temperatures.

197 **Fig. 3.** Differentially expressed genes (DEGs) related to pathogen recognition at **A)** 3 dpi and **B)** 7
 198 dpi, in CHIKV-infected *Ae. aegypti* versus uninfected controls. CTL: C-type lectin; LRIM: leucine-
 199 rich immune receptors; LRR: leucine-rich repeat-containing proteins; LRTP: leucine-rich
 200 transmembrane protein; FREP: fibrinogen related proteins; ML: Niemann-Pick receptors; GALE:
 201 galectin; PGRP: peptidoglycan recognition proteins; SCR: scavenger receptors; TEP: thioester
 202 proteins.

203 Immune signalling genes

204 We found a complete absence of immune signalling DEGs at 32 °C at the 3 dpi, with only two
 205 DEGs detected by 7 dpi (**Fig. 4**). Upregulation of *Cactus* (AAEL000709), *Toll 5A*
 206 (AAEL007619) and downregulation of *TRAF6* (AAEL028236) were only found at 18 °C (**Fig.**
 207 **4**). *Kayak* (AAEL008953) and *AP-1* (AAEL003505) were expressed at both time points at 18
 208 °C and 28 °C, but only *AP-1* was observed at 32 °C at 7 dpi. The repertoire of immune signalling
 209 genes was stable across the two time points at 28 °C and included two *Spätzle* genes
 210 (AAEL001929 and AAEL013434), *Relish 2* (AAEL007624) gene and a hypothetical protein
 211 from JAK-STAT pathway (AAEL009645).

212

213 **Fig. 4.** Differentially expressed genes (DEGs) related to immune signalling at A) 3 dpi and B) 7 dpi,
 214 in CHIKV-infected *Ae. aegypti* versus uninfected controls. HP indicates hypothetical protein.

215

216 Pathogen destruction and immune modulation genes

217 There were no pathogen destruction or related effector DEGs in mosquitoes held at 32 °C at 3
218 dpi, although *Caspase 8* (AAEL014348) was upregulated at 7 dpi (**Fig. 5A**). *Caspase 8* and
219 *Dicer-2* (AAEL006794) were upregulated at 18 °C at 3 dpi but were not differentially
220 expressed at 7 dpi. Upregulation of *Dicer-2* expression in response to CHIKV was only
221 observed at 18 °C and 28 °C. In contrast, the mosquitoes kept at 28 °C differentially expressed
222 most of the previously identified pathogen destruction mechanisms including antimicrobial
223 peptide (*AMP*) genes (*Attacin*, *Defensin* and *Cecropin*) and apoptosis genes (*Caspase 8* and
224 *IAP 1*). By 7 dpi, most expression of DEGs was suppressed at 18 °C and reduced at 28 °C. We
225 did not observe any immune modulation genes significantly upregulated at 32 °C at 3 dpi,
226 although by 7 dpi two serpins were observed (**Fig. 5 B**). Conversely, we observed three immune
227 modulation DEGs (AAEL003182: *SRPN26*; AAEL010235: allergen; AAEL006347: *apyrase*)
228 downregulated at 18 °C at 3 dpi but none at 7 dpi.

229

232 **Gene ontology (GO) mapping differs across temperature and time**

233 The lists of DEGs identified for each temperature and time point sampled were submitted to
234 the DAVID bioinformatics (V6.8) functional annotation tool. The resulting Gene Ontology
235 (GO) terms were classified using WEGO 2.0 web gene ontology annotation plotting. Gene
236 ontologies in the three major categories of Cellular Location, Molecular Function and
237 Biological Processes differed according to temperature and time of sampling post infection
238 (**Fig. 6**). At 3 dpi, a total of 14 cellular location terms were obtained from the DEGs identified
239 (**Fig. 6A** left panel) with the majority being present at 18 °C. Consistent with the low number
240 of DEGs found at 32 °C, only very few cellular location terms were mapped for this
241 temperature. Only five GO terms pertaining to cellular locations were mapped at all three
242 temperatures. At 7 dpi, a similar number of cellular locations related to DEGs was mapped as
243 for 3 dpi (n locations = 13, **Fig. 6A** right panel). The highest number of cellular locations was
244 observed for mosquitoes held at 28 °C. At 18 °C, almost all (8/9) cellular locations comprised
245 upregulated DEGs. Both 28 °C and 32 °C were similar with respect to DEG expression. Cell
246 junction, supramolecular complex, synapse and synapse part related genes were upregulated
247 only at 28 °C.

248

249 **Fig 6.** Gene Ontology analysis of differentially expressed genes (DEGs) in CHIKV-infected *Ae.*
 250 *aegypti* mosquitoes, held at three temperatures and sampled at two time points post infection (dpi). **A)**
 251 Cellular locations; **B)** Molecular functions; **C)** Biological processes.

252

253 At 3 dpi, DEGs were related to a total of 10 molecular functions (**Fig. 6B** left panel), with
 254 catalytic activity significantly differentially expressed at all temperatures. Five, 10 and 3
 255 molecular functions were differentially expressed at 18 °C, 28 °C and 32 °C respectively. Five
 256 out of six molecular functions identified in mosquitoes held at 18 °C post infection had
 257 significant DEGs (both up and downregulated) while the remaining category, behaviour, was

258 downregulated. Binding was downregulated only at 32 °C, but transporter activity was
259 upregulated. Cargo receptor activity, molecular function regulator, nutrient reservoir activity
260 and structural molecular activity were functions observed only at 28 °C. Mosquitoes held at the
261 other two temperatures had no DEGs related to these molecular functions. At 7 dpi, six out of
262 nine molecular functions were found in common across all temperatures (**Fig 6B** right panel).
263 Cargo receptor activity was only significantly upregulated at 28 °C. Molecular transducer
264 activity was observed to be upregulated at 18 °C and 28 °C, whereas nutrient reservoir activity
265 was upregulated at 28 °C and 32 °C.

266 DEGs in CHIKV-infected mosquitoes versus controls sampled at 3 dpi related 17 biological
267 processes, across the three different temperatures (**Fig 6C** left). Mosquitoes from 28 °C
268 displayed the highest number (15/17) of differentially expressed biological processes, whereas
269 those kept at 32 °C displayed the lowest (5/21). Downregulation of behaviour was unique for
270 mosquitoes held at 18 °C. On the other hand, downregulation of cell proliferation and
271 upregulation of cellular component organisation of biogenesis and development process were
272 exclusively found at 28 °C. Immune system and multicellular organismal processes were
273 downregulated at 18 °C but upregulated at 28 °C. At 7 dpi, 19 biological functions were
274 identified from DEGs across all temperatures (**Fig 6C** right), with the highest number (n=18)
275 identified at 28 °C. Upregulation of immune system process and negative regulation of
276 reproduction were exclusively found at 28 °C. The majority (6/9) of the biological processes
277 found at 18 °C consisted of upregulated DEGs. Further, 62% (8/13) of the biological processes
278 at 32 °C were significantly altered through up- and downregulation.

279

280 **Impact of temperature on functional pathway enrichment**

281 KEGG pathways obtained from the DAVID Bioinformatics analysis above were manually
282 categorised into KEGG orthologies (groups of pathways) to determine functional enrichment.

283 The vast majority of pathways altered by temperature, at both time points, were involved in
284 metabolism (**Fig. 7**, top panels denoted by **A**). At 3 dpi, 36 metabolic pathways differed
285 significantly between CHIKV-infected and control mosquitoes across all temperatures. The
286 majority of pathways found at 18 °C were downregulated, suggesting some degree of metabolic
287 shutdown in infected mosquitoes. Downregulated pathways were mostly related to
288 carbohydrate, amino acid and glycan metabolism (**Fig. 7**, top panels denoted by **A**). At 32 °C,
289 all three enriched pathways were downregulated and categorised under metabolic pathways
290 and carbohydrate metabolism. By day 7 post infection, 44 metabolic pathways differed
291 between CHIKV-infected and control mosquitoes. Unlike for 3 dpi, there was no difference in
292 enrichment of metabolic pathways at 18 °C between the two mosquito groups. By contrast, 21
293 pathways were upregulated at 32 °C at this timepoint compared to only three at 3 dpi. A greater
294 number of enriched metabolic pathways was also observed in mosquitoes at 28 °C at 7 dpi
295 versus 3 dpi. Ascorbate and aldarate metabolism (aag00053), glycerophospholipid metabolism
296 (aag00564) and ether lipid metabolism (aag00565) DEGs were only observed at 32 °C.

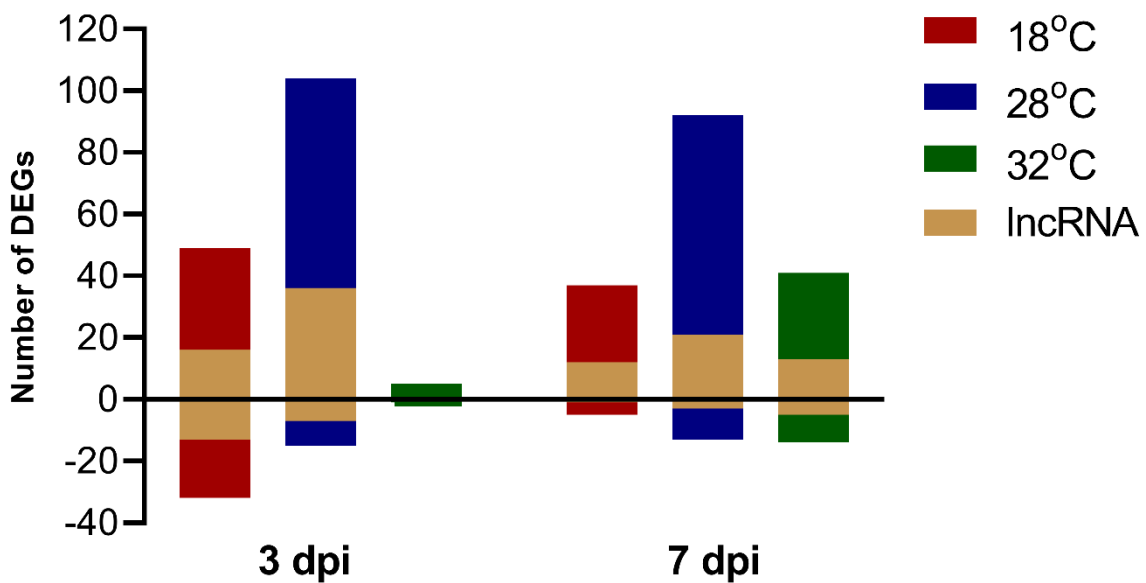

297 **Fig 7.** KEGG pathway analysis for DEGs found at 3dpi and 7dpi. **A)** metabolic pathways;
 298 **B)** genetic information processing; **C)** environmental information processing; **D)** cellular
 299 processes; **E)** organismal systems; **F)** human diseases; ‘aag’ followed by numbers indicate
 300 the KEGG pathway identification number. *Denotes both upregulated and downregulated
 301 components to the pathway.

302 Pathways involved in genetic and environmental information processing and cellular processes
303 also showed enrichment in CHIKV-infected mosquitoes compared with uninfected controls.
304 At 3 dpi, involvement of pathways in these categories was observed only at 18 °C and 28 °C,
305 with only FoxO signalling present at 32 °C. Almost half of the 15 non-metabolic pathways
306 enriched at 18 °C were downregulated (**Fig. 7B-F**). Pathways involved in response to RNA
307 virus infection such as lysosome, phagosome, peroxisome, RNA transport and RNA
308 degradation were significantly downregulated at 18 °C but upregulated at 28 °C (**Fig. 7C-D**).
309 Some pathways were exclusively differentially expressed at 28 °C, including DNA replication,
310 spliceosome, base excision repair, nucleotide excision repair, ABC transporters, Hedgehog
311 pathway, TGF-beta signalling pathway, dorso-ventral axis formation and phototransduction-
312 fly (**Fig. 7B- C**). At 7 dpi, the majority of pathways detected were upregulated (9/10, 10/13
313 and 9/12 at 18 °C, 28 °C and 32 °C, respectively; **Fig. 7**). Upregulation of phagosome and
314 downregulation of endocytosis (aag04144) were exclusively found at 18 °C whilst upregulation
315 of RNA transport and ECM receptor interaction were unique to 28 °C. On the other hand,
316 upregulation of mRNA surveillance pathway and regulation of autophagy (aag04140), but
317 downregulation of aminoacyl tRNA biosynthesis and ubiquitin-mediated proteolysis were
318 distinctly seen at 32 °C. Most mosquito groups, except those held at 32 °C for 3dpi, showed
319 enrichment of insulin resistance pathway.

320

321 **Unmapped genes in gene enrichment analysis and long non-coding RNA (lncRNA)**

322 We found 266 upregulated genes and 80 downregulated genes that could not be mapped with
323 DAVID bioinformatics cloud map (**Fig. 8; Supplementary Table 7**). Among these, 123
324 upregulated and 40 downregulated lncRNA genes were found (**Supplementary Table 8**). That
325 is, on average, nearly 50% of unmapped genes were found to comprise lncRNAs. Overall,
326 10.32% of all upregulated and 16.06% of all downregulated DEGs were lncRNAs.

327

328 **Fig 8.** Number of differentially-expressed genes (DEGs) that could not be mapped with DAVID
329 bioinformatics cloud map. The number of lncRNA genes is shown within the total DEGs.

330

331 DISCUSSION

332 Ambient temperature influences the ability of mosquitoes to transmit viruses but the molecular
333 mechanisms underpinning this are not well understood. Consistent with previous reports,
334 mosquitoes in our experiment that were held at relatively low ambient temperatures showed
335 reduced CHIKV replication. Correspondingly, we observed increased replication at 3 dpi at the
336 highest temperature used here. Distinct mosquito gene expression profiles underpinned
337 infection response at different ambient temperatures, both in the absolute number of DEGs but
338 also their gene identities. Similar to our findings for 28 °C, a recent study of mosquitoes held
339 at 30 °C found a larger number of DEGs expressed at 3 dpi in response to CHIKV [37].
340 However, exposure to 32 °C in our study elicited a surprisingly low number of genes being
341 expressed in response to CHIKV compared to control uninfected mosquitoes, particularly at
342 the earlier time point. This suppressed response is consistent with increased CHIKV replication

343 at this temperature and suggests that, at high temperatures, mosquitoes are unable to mount an
344 effective defence soon after virus infection.

345 We observed that the repertoire of immune genes differentially expressed in response to
346 CHIKV infection differed across all temperatures at each time point, contrary to what might
347 have been expected [38, 39]. The first step in eliciting an immune response is the recognition
348 of pathogens by pattern recognition receptors [40]. Similar to previous studies [37-39, 41], we
349 identified diverse PRR genes being differentially expressed in our study, including CLIP-
350 domain serine protease family B, FREP, LRR, leucine-rich transmembrane proteins, CTLs,
351 TEP and Galectins. However, we did not find any PRR DEGs common across all temperature
352 treatments at 3 dpi, while at 7 dpi only *CLIPD6* was shared. There were no immune signalling
353 or pathogen destruction-related genes found at the higher temperature (32 °C), in contrast to
354 the mosquitoes held at 28 °C at both time points, which showed extensive upregulation of genes
355 in both categories. Mosquitoes held at 18 °C and 28 °C showed significant upregulation of
356 *Dicer-2*, critical in antiviral defence in *Aedes* spp. mosquitoes [42], but there was no differential
357 expression of this at 32 °C. We observed additional immune genes become expressed at 32 °C
358 at 7 dpi as compared to 3 dpi, however this involved far fewer genes than at 28 °C and *Dicer-*
359 *2* was not differentially expressed. A limitation of our study is that we cannot rule out the
360 presence of increased RNAi (*Dicer-2*) response immediately post infection (i.e. within 24
361 hours), since our earliest time point was 3 dpi. Taken together, overall, our data suggest that
362 the immune response to CHIKV is robust at 28 °C, but key components fail to be activated at
363 higher temperatures.

364 Complementing the strong immune response observed at 28 °C, comprising Toll, IMD and
365 JAK-STAT pathway components and *Dicer-2* activity, analysis on non-classical components
366 of immunity revealed the doubling of Cytochrome P450 and serine protease gene numbers
367 from 3 to 7 dpi in response to CHIKV infection. Cytochromes are generally involved in cellular

368 functions including oxidative stress, respiration, apoptosis and xenobiotic metabolism [43].
369 The involvement of Cytochrome P450 in midguts of *Ae. aegypti* in response to DENV has been
370 previously reported [44]. Increases in number of genes coding for serine proteases have also
371 been reported for *Ae. aegypti* during DENV infection [45], thought to activate immune
372 pathways through the triggering of serine protease cascades [46]. However, serine proteases
373 may also aid arbovirus infection through proteolysis of extracellular matrix proteins,
374 facilitating viral attachment [47]. Despite these strong immune defences at 28 °C, we still
375 observed an increase in CHIKV replication over time.

376 In our study, the highest number of downregulated genes was found at 18 °C at 3 dpi.
377 Experiments on *Drosophila* indicate that exposure to non-optimal/ stressful low or high
378 temperatures causes a significant reduction of lipid storage [48]. At low temperatures, there are
379 reduced energy reserves owing to the slow accumulation of fat triggered by impaired of
380 biochemical activities. The lowering of metabolic rates may lead to a slowdown in the
381 biosynthesis of key host resources necessary to the virus lifecycle, resulting in reduced CHIKV
382 replication. Consistent with this, we also observed downregulation of genes responsible for
383 nucleic acid binding, indicating disturbance to gene regulation [49].

384 Mosquitoes have evolved various strategies to cope with different thermal conditions such as
385 acclimation, adjusting behavioural activity and synthesis of heat shock proteins [50-52]. The
386 downregulation at 32 °C and 7 dpi of two sensory genes, namely odorant binding protein and
387 long wavelength opsin, suggest a possible effect on mediators of behavioural activity. Insect
388 long wavelength opsins have previously been implicated in insect thermoregulatory responses
389 [53]. Production of HSP proteins such as HSP70 and small HSPs [54] can result in more robust
390 activation of insect defence mechanisms, and insect cells against mechanical and chemical
391 stresses caused by damage to host tissue by invading pathogens [55]. Accordingly, we found
392 significantly upregulated *hsp70* gene expression in response to CHIKV infection across all

393 temperatures in our study. Acclimation to cold temperatures also leads to elevation in HSP
394 production [56]. Consistent with this, we found that the highest number of *hsp70* genes
395 expressed at 18 °C, particularly at 3 dpi. It is worth noting that a member (*l2efl*) of the small
396 heat shock protein *hsp20* family, which has been suggested to suppress virus entry and/ interact
397 with viral proteins [57], was in the top 10 upregulated genes across all temperatures and time
398 points in our study. This is the first time, to our knowledge, that *hsp20* involvement has been
399 identified in *Ae. aegypti* in response to CHIKV infection and may be specific to this interaction,
400 as it has not been reportedly widely during arbovirus infection of mosquitoes.

401 We provide an updated list of genes involved in immune response, based on the most recent
402 genome annotation of *Ae. aegypti*. Previous studies of transcriptomic changes may be
403 hampered by limited annotation and minimal literature on how immune genes/gene
404 nomenclatures have changed from the *Ae. aegypti* reference genome [58] assembly version
405 AaegL1 released in 2007 [59] to the AaegL5.2 [60, 61] version published in 2019. A limitation
406 of our experiment is that we cannot rule out the influence of blood meal digestion in DEG
407 patterns observed at 3 dpi. Although digestion may be completed by 3 dpi at the higher
408 temperatures, at 18 °C it may take longer than three days due to a slowdown in metabolism.
409 Consistent with this, we observed significant downregulation of a zinc carboxypeptidase
410 (AAEL008609) involved in blood meal digestion [62].

411 Overall, our data suggest that temperature strongly influences the ability of mosquitoes to
412 transmit viruses and the immune response during infection. At lower temperatures,
413 downregulation of genes and conservation of resources may drive the viral replication observed
414 despite the activation of many classical and non-classical immune components. In contrast, at
415 high temperatures, the impairment of immune responses may result in shorter virus extrinsic
416 incubation periods and higher virus titers. Impaired mosquito defences may result in a greater
417 propensity for viruses to emerge in a warming climate. Conversely, impairment may also

418 impose additional strong selection pressure on mosquitoes at high temperatures, resulting in
419 altered behaviour and geographic ranges.

420 A final important observation is that time matters when dissecting response to infection, as
421 varying repertoires of genes may be expressed at different points. Our data challenge the
422 assumption that immune response to infection is constant through time in persistently infected
423 mosquitoes. There was a 10-fold decrease from 3 dpi to 7 dpi in the number of downregulated
424 genes in the number of DEGs observed at 18 °C. Conversely, a 6.5-fold increase in the number
425 of upregulated DEGs was observed at 32 °C. The number of DEGs at 28 °C remained more or
426 less constant across time points but different repertoires of genes were expressed. In parallel,
427 gene ontologies identified, and pathways enriched at these temperatures also differed.

428 In conclusion, we show that ambient temperature influences overall gene expression in
429 response to CHIKV infection and suggest that high temperatures may impair mosquito immune
430 response. Impaired mosquito responses may accelerate transmission of arboviruses and,
431 potentially, pathogen emergence. The presence of a considerable number of lncRNA,
432 pseudogenes and uncharacterised genes significantly differentially expressed in infected
433 mosquitoes highlights the need for further functional studies and annotation of *Ae. aegypti*
434 genome.

435

436 **METHODS**

437 **Mosquitoes and virus infection**

438 Five to 7-day old *Ae. aegypti* were orally challenged with virus-infected or sheep blood alone
439 (control), using methods previously described [26]. A CHIKV strain from the Asian Genotype
440 (GenBank ID: MF773560) was prepared as described in [26] and delivered in oral feeds at a
441 final pfu of 1×10^7 per ml of virus stock. Post oral challenge, mosquitoes observed to have

442 taken a blood meal were randomly allocated to three different temperatures (18 °C, 28 °C and
443 32 °C) in environmental chambers, with 70% humidity at a 12h:12h day/ night cycle.
444 Mosquitoes were then sampled at 3 and 7 post-infection. Mosquitoes were tested for the
445 presence of CHIKV in whole bodies (minus wings and legs) using qRT-PCR as previously
446 described [26].

447 **RNA extraction and NGS sequencing**

448 RNA was extracted from individual mosquito bodies using TRIzol™ reagent (Invitrogen™,
449 Thermo Fisher Scientific, USA). Samples were homogenised for 90 seconds with the addition
450 of silica glass beads (Daintree Scientific, St Helens, TAS, Australia) in a MiniBeadbeater-96
451 (Biospec Products, Bartlesville, Oklahoma, USA). Total RNA was extracted from the
452 homogenate according to the Trizol protocol. RNA was dissolved in Ultrapure™ water
453 (Invitrogen™, Thermo Fisher Scientific, USA) to make a final volume of 40 µL, and frozen at
454 -80 °C until further analysis.

455 **Sample selection and RNAseq**

456 Six mosquito bodies in which we detected the presence of CHIKV were selected from each
457 time point, for each temperature. The samples were checked for RNA quality >1.8 of A260/280
458 ratio and quantity by NanoDrop Lite (Thermo Fisher Scientific Inc.). RNA integrity was
459 checked using RIN score analysis performed in an Agilent 2100 Bioanalyzer (Agilent
460 Technologies, Palo Alto, CA, USA). Similarly, RNA extracted from uninfected control
461 mosquitoes was subjected to quality and quantity checking. A total of 72 RNA samples,
462 comprising 36 infected blood-fed and 36 uninfected blood-fed controls were subjected to
463 RNAseq, with six per each combination of time point (3 dpi and 7 dpi), and temperature (18
464 °C, 28 °C and 32 °C). Samples were sequenced on the Illumina HiSeq platform at Genewiz,
465 China. Illumina raw data generated for all samples were deposited at the Short Read Archive
466 (SRA) database under the BioProject accession number PRJNA630779.

467 **RNAseq data analysis**

468 Sequencing data obtained from Genewiz, China were subjected to quality control and mapping.
469 Raw sequences in fastq format were subjected to adapter removal and quality trimming using
470 Trim Galore (<https://github.com/FelixKrueger/TrimGalore>). Poor quality bases/reads with a
471 quality score lower than 30 and sequences with a read length shorter than 50 nucleotides were
472 removed to obtain high-quality clean data. To map the sequences, we first downloaded the
473 reference genome sequences and annotations of AegL5.2 from VectorBase (AegL5) [38],
474 the most recent annotation release of *Ae. aegypti* [51] genome. Second, RNA STAR two-pass
475 mapping approach was used to align clean reads onto the AegL5 reference genome sequence
476 and obtain gene read counts [41]. The RSEM tool was then used to quantify the expression of
477 gene isoforms [63].

478

479 **DEG identification, GO mapping and KEGG pathway analysis**

480 Differential expression analysis was performed using the DESeq2 Bioconductor package [64].
481 The comparison between the mapped read counts of the virus-infected mosquitoes vs the read
482 counts of uninfected blood-fed mosquitoes identified differentially expressed genes (DEGs).
483 Genes were significantly differentially expressed if the adjusted p-value (false discovery rate)
484 was <0.05 and showed an absolute fold change of ± 1.5 . For all DEGs, gene annotation was
485 done using the Biomart tool provided by the VectorBase database. DEG lists were further used
486 for GO, pathway enrichment and immune response analysis. DAVID bioinformatics (V6.8)
487 was used to assign GO terms and KEGG pathways information to differentially expressed
488 genes [65]. WEGO 2.0 was then used to compare and plot GO annotation results at user-
489 specified hierarchical level 2 [65]. The KEGG pathways enriched by DAVID bioinformatics
490 were manually categorized under six main categories and subcategories as defined by the
491 KEGG pathway database [36]. There were some pathways/GO terms with the presence of both

492 up and downregulated genes. This is expected when pathways encode both positive and
493 negative regulators [66]. Thus, if the upregulated gene group contains "positive" regulators and
494 downregulated one includes "negative" regulators, in general, the pathway can be considered
495 as regulated [67]. We used this approach in our descriptions of GO analysis and KEGG
496 pathway analysis. For gene IDs for which functional information could not be assigned via
497 DAVID bioinformatics (v6.8) gene enrichment analysis tool, then such genes were subjected
498 to annotation using VectorBase search and BLAST sequence similarity
499 (<https://blast.ncbi.nlm.nih.gov/Blast.cgi>).

500 **Identification of classical and non-classical immune genes**

501 We downloaded the peptide sequences of all the immune genes listed at the database
502 ImmunoDB (<http://cegg.unige.ch/Insecta/immunodb>), which possesses information on insect
503 immune-related genes and gene families [39]. We performed a similarity search using blastp
504 with the peptides given in VectorBase (<https://www.vectorbase.org/>) under the annotation
505 release AaegL5. Using an in-house script, we obtained the 10 best hits for each peptide and
506 then selected the top hit with the largest bit score, % identity and lowest E-value. Next, we
507 further searched the literature for articles using the search terms "*Aedes aegypti*" and "immune"
508 published after 2007 to ensure that we identify novel gene families/ genes, that is, the genes
509 recently discovered to link with immune response and thereby not covered in 2007 annotation
510 of *Ae. aegypti*. In addition, a manual search for immune-related gene families/ genes identified
511 VectorBase annotated genes using previously identified gene family names. Genes that were
512 related to four main categories of immune response process were considered classical immune
513 genes while the genes directly or indirectly supplementing the above four processes are
514 regarded as non-classical immune genes. The list of DEGs were compared against the list of
515 immune genes identified through both literature review and similarity screening using Venny
516 2.1. Additionally, a list of lncRNA was identified comparing conserved ID sets between

517 AaegL3.1 and AaegL5.1 gene annotation, and by including lncRNAs reported in AaegL5.2
518 [63].

519 **CHIKV read count analysis**

520 Estimation of chikungunya virus replication in infected and control *Ae. aegypti* was also
521 performed by mapping high-quality adaptor-clipped Illumina pair-end reads onto the
522 chikungunya virus genome, Asian genotype (GenBank accession no. MF773560) using
523 Burrows-Wheeler Aligner (BWA) mem (<https://arxiv.org/abs/1303.3997>). Read counts of
524 aligned reads were obtained using samtools idxstats [68]. Normalised Reads Per Million (RPM)
525 counts were calculated to quantify viral read counts. Two samples (RY-74 and RY-75) were
526 identified as outliers on the correlation plot between virus titer and normalized reads per million
527 counts and were removed from further analysis. The Mann-Whitney test was used to find
528 differences between virus read counts of any two mosquito groups. The Kruskal-Wallis test
529 was used for comparison of viral reads of multiple groups. A p-value <0.05 was considered
530 statistically significant. Statistical analyses were performed using SPSS 25 (IBM Statistics).
531 Graphs were prepared using GraphPad Prism version 8.3.0.

532

533 **ACKNOWLEDGEMENTS**

534 We thank Mr Henry Simila for technical assistance. The research presented here was funded
535 by the National Health and Medical Research Council (NHMRC) of Australia project grant
536 APP1125317 and the Royal Society of Tropical Medicine and Hygiene small grants program.
537 BMC Randika Wimalasiri-Yapa was funded by the University Grants Commission Sri Lanka,
538 The Open University of Sri Lanka and Queensland University of Technology, Brisbane,
539 Australia.
