15

16 **Abstract:**

17 Human induced pluripotent stem cells (iPSCs) have great potential for disease modeling. However, generating
18 iPSC-derived models to study brain diseases remains a challenge. In particular, the ability to recapitulate cerebellar
19 development *in vitro* is still limited. We presented a reproducible and scalable production of cerebellar organoids
20 by using the novel Vertical-Wheel single-use bioreactors, in which functional cerebellar neurons were obtained.
21 Here, we evaluate the global gene expression profiles by RNA sequencing (RNA-seq) across cerebellar
22 differentiation, demonstrating a faster cerebellar commitment in this novel dynamic differentiation protocol.
23 Furthermore, transcriptomic profiles suggest a significant enrichment of extracellular matrix (ECM) in dynamic-
24 derived cerebellar organoids, which can better mimic the neural microenvironment and support a consistent
25 neuronal network. Thus, an efficient generation of organoids with cerebellar identity was achieved for the first time
26 in a continuous process using a dynamic system without the need of organoids encapsulation in ECM-based
27 hydrogels, allowing the possibility of large-scale production and application in high-throughput processes. The
28 presence of factors that favors angiogenesis onset was also detected in dynamic condition, which can enhance
29 functional maturation of cerebellar organoids. We anticipate that large-scale production of cerebellar organoids may
30 help developing models for drug screening, toxicological tests and studying pathological pathways involved in
31 cerebellar degeneration.

32

33 **Keywords:** organoids, human pluripotent stem cells, cerebellum, large-scale production, dynamic conditions

34

35 **Introduction:**

36   The human brain represents a complex structure formed by a great diversity of neurons, astrocytes,
37 oligodendrocytes and microglia. Endogenous human brain tissue is not easily available for studying
38 neurodevelopment and neurodegenerative diseases, and it is a subject of ethical concerns. Since the discovery of
39 human pluripotent stem cells (PSCs), including embryonic and induced pluripotent stem cells (ESCs and iPSCs)
40 (Takahashi et al., 2007; Thomson, 1998), distinct approaches have emerged to differentiate them into a variety of

41 glial and neuronal cell types to model human development and neurodegenerative disorders (Ishida et al., 2016;
42 Kim et al., 2019; Liu and Zhang, 2010; Ponroy Bally et al., 2020). However, the reproducible differentiation of a
43 desired neuronal type for disease modeling under defined conditions remains a challenge, aggravated by culture
44 and cell line variability. Engineered 3D cultures resembling complex brain regions, usually called organoids, have
45 been reported (Bagley et al., 2017; Lancaster et al., 2013; Matsumoto et al., 2020; Muguruma et al., 2015; Qian et
46 al., 2018; Xiang et al., 2019). To promote PSC aggregation and generate controlled size and shape PSC aggregates,
47 scaffold-free approaches have been used, including low-cell-adhesion 96-well culture plates (Bagley et al., 2017;
48 Lancaster et al., 2013; Matsumoto et al., 2020; Muguruma et al., 2015; Xiang et al., 2019), conical tubes (Qian et
49 al., 2018) or microwell culture plates (Silva et al., 2020a), which are difficult to adapt for large scale production.
50 Furthermore, it is essential to produce organoids large enough to recapitulate tissue morphogenesis and cellular
51 organization without the limitation of oxygen, nutrients and morphogen diffusion to the cells (McMurtrey, 2016).
52 To help address this critical issue, cerebral organoids were already cultured in dynamic systems. Usually, reported
53 protocols rely on the initial neural commitment of PSCs in static conditions, followed by encapsulation of the
54 organoids in extracellular matrix (ECM)-based hydrogels and their transfer to dynamic culture conditions
55 (Lancaster et al., 2012; Qian et al., 2018). Such approach, however, may limit the potential scale-up of organoid
56 production, which is important for drug screening applications.
57   We described a new approach for the reproducible and scalable generation of organoids that adopt cerebellar
58 identity and further mature into cerebellar neurons under chemically defined and feeder-free 3D dynamic
59 conditions. Indeed, morphological structures similar to human embryonic cerebellum were firstly generated by
60 Muguruma and colleagues in static conditions (Muguruma et al., 2015). However, these organoids only recapitulate
61 the embryonic structure of cerebellar tissue and the differentiation of functional cerebellar neurons was only
62 achieved in 2D culture after organoid dissociation, using either co-culturing with animal (Muguruma et al., 2015;
63 Tao et al., 2010) and human-derived feeder cells (Wang et al., 2015), or in a co-culture free system (Silva et al.,
64 2020a). By using the novel single-use Vertical-Wheel^{TM} bioreactors (VWBRs, PBS Biotech), we are able to mimic
65 later stages of human cerebellar development *in vitro*, by easily generating high numbers of human iPSC-derived
66 aggregates and efficiently differentiating them into mature cerebellar organoids, which contain diverse types of
67 cerebellar neurons including Purkinje cells and granule cells. VWBRs were already successfully used for human
68 iPSC (Borys et al., 2020; Nogueira et al., 2019; Rodrigues et al., 2018) and mesenchymal stem cell expansion
69 (Sousa et al., 2015; de Sousa Pinto et al., 2019). The VWBRs combine a large vertical impeller and a U-shaped
70 bottom to provide a more homogeneous shear distribution inside the bioreactor, allowing a gentle and uniform
71 mixing and particle suspension with reduced power input and agitation speeds (Croughan et al., 2016). Here,
72 expression profiles from RNA sequencing (RNA-seq) of cerebellar organoids generated under static or dynamic
73 conditions were evaluated, revealing a more efficient cerebellar commitment in the latter protocol. Furthermore,
74 RNA-seq data analysis suggests a significant enrichment of ECM in dynamic conditions, avoiding the encapsulation
75 of organoids in ECM-based hydrogels and thus facilitating the large-scale production and their applicability in high-
76 throughput processes. The presence of a microenvironment that favors angiogenesis onset was also observed in
77 dynamic conditions, which can support a more complex environment sustaining a functional maturation of
78 cerebellar organoids.
79

Materials and Methods

81

Maintenance of human iPSCs. In this study, three distinct human iPSC lines, F002.1A.13 (Silva et al., 2020a), Gibco Human Episomal iPSC line (iPSC6.2, Thermo Fisher Scientific) (Burridge et al., 2011) and iPS-DF6-9-9T.B (WiCell Bank)(Junying et al., 2009) were used. All human iPSCs were cultured on Matrigel (Corning)-coated 6-

85 well plates with mTeSR™1 medium (StemCell Technologies). Full-volume medium replacement with mTESR1
86 was performed daily. Cells were passaged when the colonies covered approximately 85% of the surface area of the
87 culture dish at a split ration of 1:3, using 0.5mM EDTA dissociation buffer (Thermo Fisher Scientific)(Beers et al.,
88 2012). Two to three passages were performed before starting the differentiation protocol.
89
90 **Generation, differentiation and maturation of human iPSC-derived aggregates using Vertical-Wheel**
91 **Bioreactors.** In this work, PBS MINI 0.1 MAG VWBRs (PBS Biotech, USA) were used, which hold a maximum
92 volume of 100mL. The working volume selected was 60mL, which allows a complete covering of the impeller
93 wheel with culture medium. The protocols for seeding, operation of the vessel, and cerebellar differentiation of
94 human iPSCs are described in detail elsewhere (Silva et al., 2020a; Silva et al., 2020b). Briefly, for single-cell
95 seeding, cells grown in a culture dish were incubated with ROCK inhibitor (Y-27632, 10μM, StemCell
96 Technologies) for 1 h at 37ºC prior to harvesting with Accutase. Then, cells were treated with accutase (Sigma) for
97 7 min at 37ºC. After dissociation, single-cells were seeded in the bioreactor at a density of 250 000 cells/mL in
98 60mL of mTeSR™1 supplemented with 10μM Y-27632. To promote cell aggregation an agitation speed of 27 rpm
99 was used. After 24 hours, 80% of the medium was replaced and aggregates were maintained in mTeSR™1 without
100 Y-27632 for another 24 hours at an agitation speed of 25 rpm. From day 2 to day 21 after seeding, gfCDM was
101 used as basal medium for the differentiation (Muguruma et al., 2015; Silva et al., 2020a). Recombinant human basic
102 FGF (FGF2, 50ng/ml, PeproTech) and SB431542 (10μM, Sigma) were added to culture on day 2. Full-volume
103 medium replacement with gfCDM (supplemented with insulin, FGF2 and SB431542) was performed on day 5,
104 letting the organoids settle at the bottom of the bioreactor. On day 7, the agitation speed was changed to 30 rpm,
105 medium was fully replaced and two-thirds of initial amounts of FGF2 and SB were added. Recombinant human
106 FGF19 (100ng/ml, PeproTech) was added to culture on day 14 post-seeding, and full-volume replacement was
107 performed on day 18. From day 21, the aggregates were cultured in Neurobasal medium (Thermo Fisher Scientific)
108 supplemented with GlutaMax I (Thermo Fisher Scientific), N2 supplement (Thermo Fisher Scientific), and 50U/ml
109 penicillin/50μg/ml streptomycin (PS, Thermo Fisher Scientific). Full-volume replacement was performed every 7
110 days. Recombinant human SDF1 (300ng/ml, PeproTech) was added to culture on day 28. After 35 days of
111 differentiation, neuronal maturation was promoted by using BrainPhys Neuronal Medium (StemCell Technologies),
112 supplemented with NeuroCult SM1 Neuronal Supplement (StemCell Technologies), N2 Supplement-A (StemCell
113 Technologies), Recombinant Human Brain Derived Neurotrophic Factor (BDNF, PeproTech, 20ng/mL),
114 Recombinant Human Glial-Derived Neurotrophic Factor (GDNF, PeproTech, 20ng/mL), dibutyryl cAMP (1mM,
115 Sigma), and ascorbic acid (200nM, Sigma). One-third of total volume was replaced every 3 days.
116
117 **Aggregate size and biomass analysis**. To monitor aggregate sizes throughout time in culture, several images were
118 acquired at different time points using a Leica DMI 3000B microscope with a Nikon DXM 1200F digital camera.
119 The aggregate area was measured using ImageJ Software. Considering the aggregates as spheroids, diameters were
120 calculated based on determined area according to the equation: $d = 2 \times \sqrt{\frac{A}{\pi}}$, in which d represents the diameter
121 and A represents the area. To analyze the volume of biomass, the volume was calculated based on the determined
122 average diameter according to the equation: $V = \frac{4}{3} \times \pi \left(\frac{d}{2}\right)^3$. The total increase of biomass was calculated
123 multiplying the volume of an aggregate in average by the total number of organoids and normalized to the biomass
124 measured on day 1. The number of aggregates were manually quantified using 1mL-sample collected from the
125 bioreactor.
126

127   **Expression profiling with RNA sequencing. 1) Sample collection and RNA extraction**. F002.1A.13 iPSC line-
128   derived aggregates were collected at different time-points of cerebellar differentiation from VWBRs and static
129   conditions. For RNA extraction, aggregates were dissociated with accutase at 37ºC for 7 min. After enzymatic
130   neutralization, the cell pellet was washed with phosphate buffered saline (PBS, 0.1M) and then stored at -80ºC.
131   Total RNA was extracted from samples using High Pure RNA Isolation Kit (Roche, Cat. 11828665001), according
132   to the manufacturer instructions. **2) RNA-seq sample preparation and sequencing.** RNA libraries were prepared
133   for sequencing using Lexogen QuantSeq 3'mRNA-Seq Library Prep Kit FWD for Illumina using standard protocols.
134   Briefly, 500ng of total RNA were primed with the oligo dT primer containing Illumina-compatible linker sequences.
135   After first strand synthesis, the RNA was removed, and second strand synthesized with Illumina-compatible random
136   primers. After magnetic bead-based purification, the libraries were PCR amplified introducing the sequences
137   required for cluster generation. Sequencing was performed using NextSeq (75 cycles protocol) platforms. Base
138   calling of samples processed in NextSeq Sequencer was performed with the Real-Time Analysis (RTA) v2. **3)**
139   **Transcriptome analyses.** Quality control of raw Illumina reads was performed using FastQC v0.11.5 tool.
140   TrimGalore v0.4.4 was employed to trim read adaptors in paired-end mode, removing reads with less than 10 bases
141   and/or low-quality ends (20 Phred score cut-off). The resultant reads were aligned against the reference human
142   genome (GRCh38) using STAR v2.7.0 software, requiring uniquely mapped reads (--outFilterMultimapNmax 1)
143   and minimum alignment score (--outFilterScoreMin) of 10. BAM files with aligned reads were run through
144   featureCounts v2.2.6 (strandSpecific = 1) to produce estimated gene expression values, which were then gathered
145   in a non-normalized count matrix. Normalization of gene's read counts comparison between static and dynamic
146   protocols as well as different timepoints were done using DESeq2 v1.28.1 rlog function. PCA plot was performed
147   using plotPCA function from the same package. Heatmaps were built using pheatmap package. Significant
148   differentially expressed genes were detected with DESeq2 package and R v4.0.2. A double cut-off of 0.05 for
149   adjusted p-value and 2 for | log2(FoldChange) | was applied over DESeq2's own two-sided statistical test results.
150   Gene set enrichment analyses was performed with topGO v2.40.0, which allowed to revel the overrepresented GO
151   terms between conditions. **4) Accession numbers.** RNA-seq data for this study are available through Gene
152   Expression Omnibus (GEO) Accession Number GSE161549
153
154   **Quantitative Real-time PCR (qRT-PCR).** Total RNA was extracted at different time-points of cerebellar
155   differentiation using High Pure RNA Isolation Kit (Roche) and converted into complementary cDNA with
156   Transcriptor High Fidelity cDNA Synthesis Kit (Roche). Gene expression was analyzed using SYBR® green
157   chemistry (**Table 1**). All PCR reactions were run in triplicate, using the ViiA™7 RT-PCR System (Applied
158   BioSystems). Quantification was performed by calculating the ΔCt value using GAPDH as a reference and results
159   are shown as mRNA expression levels (2-ΔCt) relative to GAPDH.
160
161   **Tissue preparation and Immunohistochemistry.** Aggregates were fixed in 4% paraformaldehyde (PFA, Sigma)
162   for 45 min at 4ºC followed by washing in PBS and overnight incubation in 15% (v/v) sucrose at 4ºC. Aggregates
163   were embedded in 7.5%/15% (v/v) gelatin/sucrose and frozen in isopenthane at -80ºC. Twelve-μm sections were
164   cut on a cryostat-microtome (Leica CM3050S, Leica Microsystems), collected on Superfrost™ Microscope Slides
165   (Thermo Scientific) and stored at -20ºC. For immunostaining, sections were de-gelatinized for 45 min in PBS at
166   37ºC, incubated in 0.1 M Glycine (Millipore) for 10 min at room temperature (RT), permeabilized with 0.1% (v/v)
167   Triton X-100 (Sigma) for 10 min at RT and blocked with 10% (v/v) fetal bovine serum (FBS, Gibco) in TBST (20
168   mM Tris-HCl pH 8.0, 150 mM NaCl, 0.05 % v/v Tween-20, Sigma) for 30 min at RT. Sections were then incubated
169   overnight at 4ºC with the primary antibodies diluted in blocking solution (**Table 2**). Secondary antibodies were
170   added to sections for 30 min (goat anti-mouse or goat anti-rabbit IgG, Alexa Fluor®–488 or –546, 1:400 v/v dilution,

171 Molecular Probes) at RT and nuclear counterstaining was performed using 4',6-diamidino-2-phenylindole (DAPI,
172 1.5 µg/mL; Sigma). After brief drying, sections were mounted in Mowiol (Sigma). Fluorescence images were
173 acquired with Zeiss LSM 710 Confocal Laser Point-Scanning Microscopes.
174
175 **Single cell calcium imaging.** Functional maturation was evaluated by single cell calcium imaging (SCCI) to
176 analyze the intracellular variations of Ca^{2+} following stimulation with 50mM KCl and 100µM histamine (Sigma).
177 2-5 days before evaluation, aggregates were re-plated on Glass Bottom Cell Culture Dish (Nest) previously coated
178 with poly-L-ornithine (15µg/mL, Sigma) and laminin (20µg/mL, Sigma). At different time points of differentiation,
179 neurons were loaded with Fura-2 AM (5 µM, in normal Krebs solution with the following composition: NaCl
180 (132mM), KCl (4mM), $MgCl_2$ (1.4mM), $CaCl_2$ (2.5mM), D-(+)-glucose (6mM) and HEPES (10mM) - pH 7.4
181 adjusted with NaOH - and incubated at 37ºC for 45 min. Fura-2 AM loaded cells were sequentially excited both at
182 340nm and 380nm, for 250ms at each wavelength, using an inverted microscope with epifluorescent optics and
183 equipped with a high speed multiple excitation fluorimetric system (Lambda DG4, with a 175W Xenon arc lamp).
184 The emission fluorescence was recorded at 510nm by a CDD camera. Cells were stimulated using 100µM histamine
185 or high potassium Krebs solution (containing 50mM KCl, isosmotic substitution with NaCl), as reported elsewhere
186 (Rodrigues et al., 2017; Xapelli et al., 2014).
187
188 **Patch Electrophysiology.** For electrophysiological evaluation, 2-5 days before the analysis aggregates were gently
189 dissociated using accutase (Sigma) and re-plated on coverslips coated with poly-L-ornithine (15µg/mL, Sigma) and
190 Laminin (20µg/mL, Sigma). Whole cell patch-clamp recordings were obtained from generated neurons using an
191 upright microscope (Zeiss Axioskop 2FS) equipped with differential interference contrast optics using a Zeiss
192 AxioCam MRm camera and a 40x IR-Achroplan objective. During recordings, cells were continuously perfused
193 with artificial cerebrospinal fluid containing: 124mM NaCl, 3mM KCl, 1.2mM NaH_2PO_4, 25mM $NaHCO_3$, 2mM
194 $CaCl_2$, 1mM $MgSO_4$ and 10mM glucose, which was continuously gassed with $95\%O_2/5\%$ CO_2. Recordings were
195 performed at room temperature in current-clamp [holding potential (Vh) = −70 mV] with an Axopatch 200B (Axon
196 Instruments) amplifier, as performed in (Felix-Oliveira et al., 2014). Briefly, patch pipettes with 4 to 7 MΩ
197 resistance when filled with an internal solution containing: 125mM K-gluconate, 11mM KCl, 0.1mM $CaCl_2$, 2mM
198 $MgCl_2$, 1mM EGTA, 10mM HEPES, 2mM MgATP, 0.3mM NaGTP, and 10mM phosphocreatine, pH 7.3, adjusted
199 with NaOH. 280-290 mOsm were used to record action potential activity. Acquired signals were filtered using an
200 in-built, 2-kHz, three-pole Bessel filter, and data were digitized at 5 kHz under control of the pCLAMP 10 software
201 program. The junction potential was not compensated for, and offset potentials were nulled before gigaseal
202 formation. The resting membrane potential was measured immediately upon establishing whole-cell configuration.
203 Firing patterns of cerebellar neurons were determined in current-clamp mode immediately after achieving whole-
204 cell configuration by a series of hyperpolarizing and depolarizing steps of current injection (500ms). Firing potential
205 were also determined through the application of two depolarizing steps of current injection of 10ms, separated by
206 80ms.
207

208

209 **Results**
210
211 **Production of size-controlled human iPSC-derived aggregates leads to an efficient neural commitment.**
212 The generation of human iPSC-derived organoids starts by cell aggregation to mimic the 3D structure and
213 recapitulate both organization and functionality of human organs. The aggregation process is a critical step to obtain
214 a homogeneous outcome in the efficiency of differentiation with high yield of viable organoids and increased

215 reproducibility of the protocol (Xie et al., 2017). We initiated the protocol by promoting cell aggregation using
216 VWBRs (**Supplementary Fig. 1a**), in which single-cell seeding was performed at 250 000 cells/mL in 60 mL of
217 medium and with an agitation speed of 27 rpm (**Fig. 1a**). After 24 hours, cells were able to efficiently aggregate
218 (**Supplementary Fig. 1b**) and homogeneously shaped aggregates were obtained (day 1, **Fig. 1b**). Distribution of
219 diameters showed that aggregate size continues to increase from day 1 to 5, achieving similar size between different
220 iPSC lines. Furthermore, homogeneous size and shape aggregates were observed when differentiation was initiated
221 at day 2 and their spheroid-like structure was maintained during this initial neural commitment and differentiation
222 (**Fig. 1b**). Further analysis of aggregate diameters revealed that organoids were able to grow in size until day 35
223 (**Fig. 1c**)**,** with exception of iPSC6.2 cell line that presented no differences between day 21 and 35. A large number
224 of iPSC-derived organoids can be generated with the bioreactor using a straightforward methodology, achieving
225 about 350 ± 52 (mean $\pm$ SEM) aggregates/mL 24 hours after seeding. This number decreased at day 2 but remained
226 constant until the end of the cerebellar commitment, achieving 3201 ± 123 (mean $\pm$ SEM) organoids in a VWBR
227 with a working volume of 60 mL (**Fig. 1d** and **Supplementary Fig. 1c**). Probably, the merging of individual
228 aggregates was promoted by the decrease in the agitation speed from 27 to 25 rpm, since biomass analysis
229 demonstrated that the total volume of biomass increased up to ~4-fold until day 7, achieving a ~6-fold increase on
230 day 35 of differentiation (**Fig. 1e** and **Supplementary Fig. 1d**).
231 To induce neural commitment, aggregates were cultured in neural medium supplemented with SB431542, fibroblast
232 growth factor 2 (FGF2) and insulin, which are sufficient to promote neural differentiation with moderate
233 caudalization of the neuroepithelium that is essential to mid-hindbrain patterning. Subsequently, fibroblast growth
234 factor 19 (FGF19) and stromal cell-derived factor 1 (SDF1) were sequentially introduced in the culture to promote
235 tissue polarity and generate different cerebellar progenitors. The pluripotency and self-renewal transcript *OCT4* was
236 detected in human iPSCs on day 0 and upon neural induction its mRNA levels were down-regulated to almost
237 undetectable levels by day 7 (**Fig. 1f**). Consistent with this significant downregulation of the pluripotency gene, the
238 mRNA levels of *PAX6*, which is a transcription factor driving neurogenesis and important for neural stem cell
239 proliferation (Sansom et al., 2009; Thakurela et al., 2016), significantly increased, showing that an efficient neural
240 commitment was already reached by day 7 (**Fig. 1f**). Immunofluorescence analysis further supports that an efficient
241 neural commitment of the iPSC-derived aggregates is achieved by day 7 of differentiation, with most of cells within
242 the aggregates expressing the neural progenitor marker NESTIN (**Fig. 1g**). The cryosections of organoids also
243 revealed many structures reminiscent of the neural tube, expressing the neural markers PAX6 and SOX2 (**Fig. 1g**).
244 Furthermore, these neural tube-like structures showed apico-basal polarity with PAX6 and SOX2 co-stained
245 progenitors found at the luminal (apical) side marked by strong expression of apical marker N-cadherin (NCAD,
246 **Fig. 1g**).
247
248 **Induction of cerebellar identity in 3D dynamic culture conditions.**
249 During human development, the territory that gives rise to the cerebellum is located in one of the hindbrain
250 segments, which comprises the most anterior zone of the hindbrain caudally to the mid-hindbrain boundary (MHB),
251 the isthmic organizer (IsO)(Zervas et al., 2004), and is established by differential expression of several transcription
252 factors (Watson et al., 2015). The expression levels of *OTX2* and *GBX2* transcripts (**Fig. 2a**), that define the
253 molecular limits of MHB, were significantly upregulated by day 7, together with those of *FGF8*, *EN2* and *PAX2*,
254 which are crucial transcription factors involved in IsO specification (Chi et al., 2003; Joyner, 1996; Martinez et al.,
255 1999) (**Fig. 2a**). Immunostaining analysis of organoids supports the efficient self-formation of IsO tissue, staining
256 for OTX2 and EN2 by day 14 (**Fig. 2b, *i and ii***). Therefore, signals from this organizer center, including FGF8
257 (**Fig. 2a**), were able to stimulate the generation of cerebellar territory (Sasai, 2013), supported by expression of
258 PAX2 (**Fig. 2b, *iii***), a marker for GABAergic interneuron precursors in the developing cerebellum (Maricich and

259   Herrup, 1999), and BARHL1 (**Fig. 2b,** *iv*), a marker for glutamatergic progenitors during cerebellar development
260   (Li, 2004). The validation of efficient neuronal differentiation was performed by transcriptomic analysis and
261   supported by gene ontology (GO) analysis for upregulated genes on day 14 compared with day 0 (**Supplementary**
262   **Fig. 1e-f**). The differential expression analysis between days 14 and 0 demonstrated an enrichment of genes on day
263   14 that are crucial for metencephalon development, the tissue that differentiates into pons and cerebellum, and
264   further cerebellar differentiation (**Fig. 2c**), including *EN2*, *PAX2* and *BARLH1*, supporting an effective cerebellar
265   commitment in human iPSC-derived organoids already by day 14. By day 21, human iPSC-derived organoids
266   displayed continuous neuroepithelial layer with PAX6$^+$ neural progenitors on the surface with few TUJ1$^+$ newborn
267   neurons within the organoid (**Fig. 2d,** *i*). Furthermore, consistent with cerebellar identity, BARHL1$^+$ progenitors
268   self-organized into continuous layers (**Fig. 2d,** *ii*) basally located to proliferating SOX2$^+$ progenitors (**Fig. 2d,** *iii*).
269   Other types of cerebellar progenitors were found by day 21. These cells were positive for OLIG2, a marker of
270   neurogenic progenitors of Purkinje cells (Seto et al., 2014), and were dispersed within the organoids (**Fig. 2d,** *iv*).
271   On day 35, after treatment with chemokine that regulates cerebellar migration (Bagri et al., 2002), SDF1, GO
272   analysis of significantly upregulated genes (compared to day 0) revealed enrichment of neurological processes,
273   including neuron migration and synaptic processes (**Supplementary Fig. 1g-h**), supporting the reorganization of
274   the neuroepithelium and initiation of neuronal maturation. Human-iPSC derived organoids were polarized by day
275   35, with staining for ZO1 (**Fig. 2e,** *i*), an apical marker, on the presumably apical side of the tissue. Two different
276   structures can be observed, neural tube-like structures enclosed within the organoid with apical side towards the
277   lumen (**Fig. 2e,** *i,* asterisk), and a continuous neuroepithelium that contains the apical side on the outer surface of
278   the organoid (**Fig. 2e,** *i,* arrowheads), probably resulting from merging of neural tube-like structures promoted by
279   SDF1 addition (Muguruma et al., 2015). In both cases the internal layer organization maintained the same pattern,
280   with a layer of proliferating progenitors SOX2$^+$ (**Fig. 2e,** *ii*) and PAX6$^+$ always found on the apical side (**Fig. 2e,**
281   *iii*), and TUJ1$^+$ neuronal cells disposed basally to PAX6$^+$ neural progenitors within the organoids (**Fig. 2e,** *iii*).
282   Consistent with this organization, post-mitotic BARHL1$^+$ glutamatergic cerebellar progenitors were located basally
283   within the organoid (**Fig. 2e,** *iv*). Other cerebellar progenitor populations were detected by day 35, including cells
284   expressing PAX2 (**Fig. 2e,** *v*) and few dispersed cells expressing CORL2 (**Fig. 2e,** *vi*), a marker for precursors of
285   Purkinje cells (Nakatani et al., 2014). The differential expression analysis between days 35 and 0 supported an
286   efficient cerebellar commitment and differentiation (**Fig. 2f**), which was validated by qRT-PCR, with significant
287   expression of transcripts encoding specific markers for different types of cerebellar progenitors (**Fig. 2g**). These
288   markers included GABAergic cerebellar progenitors: *KIRREL2* (essential regulator of GABAergic neuron
289   development(Mizuhara et al., 2010)), *PAX2*, *OLIG2* and *CORL2*, and glutamatergic precursors: *PAX6*, *ATOH*1
290   (essential for genesis of granule cells (Ben-Arie et al., 1997) and *BARLH1*.
291
292   **Identification of different functional cerebellar neurons in dynamic culture of cerebellar organoids.**
293   Further maturation of cerebellar organoids was promoted by culturing them in BrainPhys^{TM} medium supplemented
294   with BDNF and GDNF. Gene expression analysis showed, by day 56, the expression of *GAD67* and *VGLUT1*
295   transcripts (**Supplementary Fig. 2a**), which are present in GABAergic and glutamatergic neurons, respectively,
296   and this was maintained until day 80, suggesting the presence of these two major neuronal subtypes in the organoids.
297   Immunostaining analysis further revealed the presence of specific markers for distinct types of cerebellar neurons.
298   The major glutamatergic cerebellar neurons, the granule cells, were detected by co-staining for PAX6 and MAP2
299   (**Fig. 3a**). Interestingly, immunofluorescence using antibodies to PAX6, expressed early in neural progenitors and
300   later in cerebellar granule cells (Swanson et al., 2005), and MAP2, a neuron-specific microtubule associated protein,
301   revealed a robust organization within organoids. A dense layer of PAX6$^+$/MAP2$^-$ precursors was detected, whereas
302   MAP2$^+$ fibers were distinguished basally to the progenitor's layer by day 56 of differentiation (**Fig. 3a,** *i*), and the

303   co-localization of PAX6$^+$ cells with MAP2$^+$ neuronal network (**Fig. 3a, *ii***), indicated the presence of mature granule
304   cells. Along the maturation, the initially large PAX6$^+$ neuroepithelium became smaller while, simultaneously, the
305   MAP2$^+$ region was extended (**Fig. 3a**). In some organoids a mature neuronal network was formed, without the
306   presence of neural progenitors (**Fig. 3a, *iv***), whereas in other cases a niche of PAX6$^+$ progenitors remained until
307   day 80 (**Fig. 3a, *v***). Also, other types of glutamatergic cerebellar cells seem to be found, including unipolar brush
308   cells staining for TBR2 and MAP2 (**Fig. 3b**) and deep cerebellar projection neurons expressing TBR1 and MAP2
309   (**Fig. 3c**). Purkinje cells, the class of GABAergic neurons within the cerebellum with a most elaborated dendritic
310   arbor, expressing the calcium-binding protein calbindin (CALB), were detected within a compact meshwork along
311   the surface of organoids (**Fig. 3d**). Some of the CALB$^+$ cells were also positive for Purkinje cell-specific glutamate
312   receptor GRID2 (**Fig. 3e**), indicating the presence of mature Purkinje cells. Within the neuronal network, cells
313   expressing parvalbumin (PVALB) were also found, and their non-overlapping expression with CALB identifies
314   them as GABAergic interneurons (**Fig. 3f**). Golgi cells, another GABAergic cerebellar cell type, were also detected
315   by staining for neurogranin (NRGN) and PAX2 (**Fig. 3g**). In agreement with immunofluorescence analysis, the
316   quantification of transcripts encoding for markers of distinct cerebellar neurons also demonstrated their robust
317   expression during the maturation protocol (**Fig. 3h**). Significant levels of mRNA encoding for specific markers of
318   Purkinje cells were detected by qRT-PCR analysis (**Fig. 3i**), including *L7/PCP2* (Purkinje cell protein 2), *GRID2*,
319   *CBLN1* (Cerebellin 1 Precursor), *LHX5* (LIM-homeodomain transcription factor) and *ALDOC* (aldolase C, a brain
320   type isozyme of a glycolysis enzyme).
321   To evaluate the maturation in cerebellar organoids, we performed single-cell calcium imaging. For that, organoids
322   were gently dissociated, and single cells were stimulated with 50 mM KCl and 100 µM histamine. KCl treatment
323   leads to neuron depolarization increasing intracellular calcium concentration, whereas histamine stimulation
324   increases calcium concentration in progenitor cells. Thus, we quantified the percentage of KCl responsive cells,
325   presenting a histamine/KCl ratio below 0.8. Quantification of the percentage of neurons in different human iPSC
326   lines demonstrated that this percentage varied between 37.5% and 82.4% within the organoids by day 50 (**Fig. 3j**).
327   Nevertheless, the organoids from all cell lines presented a gradual and time-dependent neuronal differentiation,
328   achieving 69% to 87% of neurons at the end of the differentiation protocol (**Fig. 3j**). These results were consistent
329   with the presence of cell niches containing KI67$^+$, SOX2$^+$ and PAX6$^+$ neural progenitors during all maturation
330   process (**Supplementary Fig. 2b-g**), retained until day 80 of differentiation. Furthermore, the electrophysiological
331   properties of differentiated neurons were evaluated by patch-clamp recordings after organoid dissociation and re-
332   plating. The differentiated neurons within organoids on day 80 exhibited fire action potential after a continuous
333   current injection (**Fig. 3l**) and were able to respond to two different current injections separated by 10ms (**Fig. 3k**),
334   demonstrating their capability for depolarizing, repolarizing and recovering. Thus, organoids in this dynamic
335   condition were maintained viable for up to 80 days (**Supplementary Fig. 2h**), containing different types of
336   functional cerebellar neurons.
337
338   **Dynamic culturing condition allows more efficient mid-hindbrain commitment and faster cerebellar**
339   **differentiation.**
340   A robust cerebellar commitment and differentiation was previously demonstrated using a static culture system(Silva
341   et al., 2020a). However, in static condition we found that organoids tend to coalesce starting from day 21 of
342   differentiation, forming large macroscopic structures with a dense cell mass (**Supplementary Fig. 3a**), which might
343   resist to diffusion of oxygen, nutrients and morphogens. Differently, in VWBRs, organoids exhibited a pronounced
344   epithelization similar to neural tube structures with luminal space (**Supplementary Fig. 3a**). The analysis of
345   diameter distributions reveled a more homogeneous aggregate size during cerebellar differentiation in dynamic
346   condition when compared with static culture (**Supplementary Fig. 3b**). Likewise, at the end of cerebellar

347 commitment, much larger aggregates were present in static condition, reaching more than 1000 μm in some cases
348 (**Supplementary Fig. 3b**).
349 To determine the impact of dynamic culturing condition on cerebellar commitment and differentiation, a
350 transcriptomic analysis of organoids derived from static and dynamic differentiations was performed. Principal
351 component analysis (PCA) demonstrated considerable transcriptomic differences between organoids obtained in
352 static and dynamic conditions at different timepoints (**Fig. 4a**). The global gene expression profiles showed a
353 significant clustering of samples by conditions and differentiation stage, in which PC1 represents 54% of variance
354 (**Fig. 4a**), probably related with differentiation progress, followed by 27% of variance captured by PC2 (**Fig. 4a**),
355 suggesting differences between static and dynamic conditions. By day 14, GO analysis of significantly upregulated
356 genes in the dynamic protocol (**Fig. 4b-c**) when compared with static conditions showed enrichment of
357 regionalization (GO:0021871; GO:0021978) and pattern specification processes (GO:0009952, **Fig. 4c**), related
358 with the self-organization and patterning of cells. Interestingly, midbrain development processes were enriched in
359 dynamic conditions, confirmed by higher number of normalized read counts of transcripts of representative genes
360 annotated in the midbrain development (**Supplementary Fig. 3c**). Nevertheless, when we evaluated the top 20
361 genes that contributed for this difference in the normalized read counts, some of the transcripts that were upregulated
362 in dynamic protocol by day 14 are also annotated and reported to be involved in hindbrain development (4/8 genes,
363 **Supplementary Fig. 3d**), suggesting a possible more efficient mid-hindbrain patterning in the dynamic protocol
364 by day 14. In addition, the analysis of transcripts annotated in cerebellar development showed a higher expression
365 in dynamic conditions by day 14 and achieved similar levels at day 35 (**Fig. 4d**), suggesting a faster cerebellar
366 differentiation in the dynamic protocol when compared with static. By qRT-PCR analysis, the mRNA levels of
367 transcripts critical for cerebellar development, including *OTX2*, *EN2*, *PAX2*, *PAX6* and *KIRREL2*, and those
368 expressed in cerebellar progenitors, such as *ATOH1*, *BARHL1*, *OLIG2* and *CORL2*, were found up-regulated in
369 dynamic conditions (**Fig. 4e**), supporting an accelerated cerebellar commitment and further differentiation. On the
370 other hand, by day 35 no significant differences were observed in the expression of mRNA levels for *ATOH1*,
371 *BARLH1*, *OLIG2* and *CORL2* by qRT-PCR between different culture conditions (**Supplementary Fig. 3e**), as
372 expected and demonstrated in **Fig. 4d**.
373
374 **Shear forces promote a significant enrichment of extracellular matrix during cerebellar differentiation.**
375 Mechano-transduction and hemodynamic forces represent essential regulators of early differentiation events during
376 embryonic development(Culver and Dickinson, 2010). Therefore, hydrodynamic shear induced by fluid flow may
377 promote stem cell differentiation toward a specific germinal layer, depending on its magnitude and duration(Wolfe
378 et al., 2012). To determine the impact of shear stress on cerebellar organoids, the transcriptome adaptations to
379 dynamic conditions during cerebellar differentiation were analyzed. Gene set enrichment analysis (GSEA) of
380 significantly upregulated genes (Log2 FC > 2 and adjusted p-value < 0.05, **Supplementary Fig. 4a**) during
381 cerebellar differentiation revealed enrichment in pattern specification (GO:0009952), regionalization
382 (GO:0021978) and morphogenesis processes (GO:0048562; GO:0048646) in dynamic culture versus the static
383 counterpart (**Fig. 5a**), as well as biological processes involved in axon guidance and neuron migration (**Fig. 5a**).
384 Extracellular matrix (ECM) organization was detected in dynamic conditions by GSEA, supported by higher
385 number of normalized read counts of transcripts of representative genes annotated to the ECM organization in
386 dynamic condition by days 14 and 35 (**Supplementary Fig. 4b**). Analysis of differentially expressed transcripts
387 responsible for ECM organization in dynamic conditions revealed high levels of the proteoglycan *ACAN* and the
388 link protein *TNC* (**Fig. 5b**), both of which are reported to be highly expressed in the neural ECM(Soleman et al.,
389 2013). *SULF1*, which encodes for sulfatase 1 playing an important role in the neurite outgrowth during postnatal
390 cerebellar development(Kalus et al., 2015), was found upregulated in the dynamic protocol. *LAMA2B*, the only

391 laminin subunit identified to be enriched in the dynamic protocol (**Fig. 5b**), has been demonstrated to be needed for
392 proper synapse assembly(Sann et al., 2008). In addition to this laminin subunit, different genes involved in integrin
393 cell surface interactions (HSA-216083) were found enriched in dynamic culture, including *FBN1, ITGA2, ITGA8*
394 and *ITGB5* (**Fig. 5b**). Furthermore, dynamic cultures of cerebellar organoids presented a collagen-rich ECM, with
395 increased expression of *COL4A5, COL6A3* and *COL9A1* transcripts (**Fig. 5b**), involved in NCAM signaling for
396 neurite out-growth (HSA-375165) and axon guidance (HSA-422475) processes. Genes belonging to ECM
397 (GO:0030198; GO:0031012; **Supplementary Fig. 4c**) and extracellular region (GO:0005576) components GO
398 terms were particularly upregulated at day 35 for dynamic conditions (**Supplementary Fig. 4c**). The presence of
399 extracellular components was further evaluated by immunostaining on day 35, revealing the expression of
400 LAMININ (**Fig. 5c, *i***), FIBRONECTIN (**Fig. 5c, *ii and iv***) and COLLAGEN I (**Fig. 5c, *iii and iv***), which was
401 maintained until the end of differentiation (**Supplementary Fig. 4d**). Furthermore, AGGRECAN (**Fig. 5c, *v***) and
402 VERSICAN (**Fig. 5c, *vi***), which are heparin sulfate proteoglycans highly expressed in neural ECM(Howell and
403 Gottschall, 2012), were also observed by immunostaining on day 35 along with SYNAPSIN (**Fig. 5c, *v and vi***), a
404 presynaptic phosphoprotein fundamental for the regulation of synaptic transmission. This demonstrates a possible
405 connection between synaptic processes and some elements of the ECM(De Luca et al., 2020). In addition to ECM
406 organization, cerebellar differentiation in dynamic conditions also appeared to enhance cell adhesion processes
407 when compared with static culturing (**Fig. 5a**). The differentially expressed genes annotated in cell adhesion process
408 that were found upregulated in dynamic culture include *ALCAM*, *BCL2*, *EPHA7, FLRT2, LAMB2, LRRN2,*
409 *PLXNA4, RELN, TNC* and *UNC5D* transcripts (**Fig. 5d**), which are also involved in axon (GO:0061564) and neuron
410 projection development (GO:0031175), supporting an efficient neuronal differentiation. Interestingly, in addition
411 to neuronal transcripts, cell adhesion genes involved in circulatory system development (GO:0072359), including
412 *ACVR1, ADAMTS9, ANGPT2, BMP2, BMP4, COL1A1, DSP, EPHA2, FBN1, FLRT2, FOXJ1, PPARA, CD36* (**Fig.**
413 **5d**), and regulation of vasculature development (GO:1901342), like *ADAMTS9, ANGPT2, BMP4, EPHA2, WNT4*
414 (**Fig. 5d**), were found differentially expressed in organoids derived from dynamic culture when compared with
415 static. Thus, fluid flow established by agitation in the dynamic protocol may activate additional transcriptional
416 regulation of genes involved in angiogenesis(Wolfe and Ahsan, 2013). Some significantly downregulated genes
417 (Log2 FC < -2 and adjusted p-value < 0.05) in dynamic culture versus the static counterpart during cerebellar
418 differentiation were detected, however none biological processes associated with these genes were strongly
419 enriched.
420
421 **Transcriptional modulation of genes involved in angiogenic processes by dynamic condition.**
422 Neurogenesis and angiogenesis are two different processes that seem to be tightly coupled during embryonic neural
423 development. Nascent blood vessels were reported to actively contact dividing neural stem cells and have a function
424 in their behavior, impacting proper brain development (Di Marco et al., 2020). To further understand how culturing
425 cerebellar organoids in dynamic condition impacts on angiogenic transcriptional profiles, we analyzed the number
426 of normalized read counts of representative genes annotated in the sprouting angiogenesis process (GO:0002040).
427 An increased expression of these transcripts was detected in dynamic condition by day 35 (**Fig. 6a**). Among the
428 top 20 genes that contributed the most to the observed differences, *BMP4, ESM1, EPHA2* and *ADAMST9* transcripts
429 were detected at high levels in dynamic cultures by day 35 (**Supplementary Fig. 5a**). While *ESM1* and *EPHA2*
430 are essential regulators of angiogenesis, modulating endothelial cell behavior and migration (Brantley-Sieders et
431 al., 2004; Rocha et al., 2014), *ADAMST9* is expressed by microvascular endothelial cells (Koo et al., 2010), being
432 abundantly present in the central nervous system (CNS, Gottschall and Howell, 2015). The expression of these key
433 genes was confirmed by qRT-PCR, showing a significantly higher mRNA levels in dynamic condition in
434 comparison with static culture at day 35 of differentiation (**Fig. 6b**), which were maintained at high levels until day

435 80 in 3D cerebellar organoids when compared with day 0 (**Supplementary Fig. 5b**). The proteins encoded by these
436 transcripts have been reported to act by binding directly to the ECM (Rocha et al., 2014). Thus, we next assessed
437 the transcriptional modulation of ECM organization and sprouting angiogenesis processes across cerebellar
438 differentiation using static and dynamic protocols. Interestingly, the expression variation of transcripts annotated in
439 these two processes was very similar, with an increased expression from day 0 to 14 in both conditions (**Fig. 6c**).
440 Thereafter, expression dropped in static conditions and increased until day 35 in the dynamic protocol (**Fig. 6c**).
441 Immunostaining also confirmed the presence of CD31$^+$ cells among LAMININ$^+$ ECM (**Fig. 6d**), suggesting a
442 possible interaction between ECM enrichment and angiogenesis onset. Additionally, this dynamic condition was
443 significantly enriched for collagen trimer and blood vessel development-specific gene signature (**Supplementary
444 Fig. 5c**), confirmed by staining for CD34 and COLLAGEN I (**Supplementary Fig. 5d**). Sprouting angiogenesis is
445 reported to be usually initiated by hypoxia and afterwards the maturation and stabilization of capillaries requires
446 ECM deposition, as well as shear stress and other mechanical signals (Chien, 2007). Therefore, we evaluated the
447 enrichment of transcripts involved in response to mechanical stimulus (GO:0009612) and cellular response to
448 hypoxia (GO:0071456). In contrast to cellular response to hypoxia, where no substantial differences were identified
449 between static and dynamic condition (**Fig. 6e**), genes annotated in response to mechanical stimulus were essentially
450 enriched in the dynamic protocol (**Fig. 6e**). Interestingly, HIF1α transcriptional activation was found downregulated
451 in the dynamic protocol in comparison with static conditions, based on top 100 genes (**Supplementary Fig. 5e**),
452 ruling out the contribution of hypoxia to activate the angiogenic process in the dynamic system. Based on these
453 results, the onset of angiogenesis in the dynamic condition might be triggered by two different signaling pathways,
454 either by ECM or mechanical stimulus (**Fig. 6f**). In the CNS, angiogenesis seems to be promoted by ECM signaling
455 supported by NRP1 expression, which interacts with ABL1 and CDC42, triggering the angiogenic process in a
456 VEGF-independent manner (Fantin et al., 2015; Raimondi et al., 2014) (**Fig. 6f**). On the other hand, shear stress
457 was reported to stimulate the expression of VEGFR2 mediated by induction of KLF2 (dela Paz et al., 2012; Renz
458 et al., 2015) (**Fig. 6f**). Thus, we quantified the mRNA levels of these two candidates, *NRP1* and *KLF2*, as well as
459 *VEGFA*, to evaluate the contribution of ECM and shear stress to the increased angiogenic pathway expression
460 observed in dynamic cerebellar organoid cultures. *NRP1* and *KLF2* transcripts show a marked increase throughout
461 the dynamic differentiation protocol, achieving significantly higher levels in dynamic condition in comparison with
462 static by day 35 (**Fig. 6g**). Despite significant differences in *KLF2* mRNA levels between static and dynamic
463 protocols, no differences in the expression of *VEGF2A* mRNA was observed by day 35 (**Fig. 6g**). From day 35,
464 while *NPR1* mRNA levels were maintained constant until the end of the cerebellar differentiation (**Fig. 6h**), *KLF2*
465 transcript expression continued to increase significantly until day 80 (**Fig. 6h**), which was accompanied by a slight
466 but statistically significant increase of *VEGFA* levels from day 14 until day 80 of differentiation (**Fig. 6h**).
467 Therefore, a possible combination of ECM and mechano-transduction pathways may contribute for the onset of the
468 angiogenic fate, which leads to a significant expression of CD31 and CD34 until day 80 of cerebellar differentiation
469 (**Supplementary Fig. 5f-g**). Human protein-protein interactome network for genes responsible for the modulation
470 of angiogenic processes observed during differentiation confirmed that transcripts annotated in integrin-mediated
471 signaling and response to stress play an active role in the regulation of angiogenesis, however, they also have an
472 important function in neuronal processes such as, for example, neuron projection morphogenesis (**Fig. 6i**).
473 Interaction between different gene clusters demonstrated that a common activation of neuronal and angiogenic fate
474 may be achieved throughout the cerebellar differentiation protocol, and we hypothesize that this may be important
475 for the higher degree of neuronal differentiation observed in dynamic condition.
476
477
478

Discussion

We reported a dynamic culture system able to generate human iPSC-derived cerebellar organoids, which matured into functional cerebellar neurons, using the novel VWBRs. The large-scale production of cerebellar organoids represents an important advance for automated high-throughput drug screening, as well as in regenerative medicine applications for neurodegenerative diseases that affect the cerebellum. Previous studies have mainly reported the scalable differentiation of PSC into neural progenitors and functional neurons (Bardy et al., 2013; Miranda et al., 2016; Rigamonti et al., 2016), lacking the recapitulation of structural cell organization seen during human embryonic development, as well as the ability to maintain these 3D structures containing functional neurons for long periods of time.

Dynamic condition allows a reproducible and large-scale generation of organoids.

By using the VWBRs, we applied a novel mixing mechanism generated by a large vertical wheel that rotates around the horizontal axis, and allows gentle and uniform fluid mixing (Croughan et al., 2016). Therefore, we ensured that uniform exposure of neural organoids to signaling molecules was reached. Moreover, the operation time and complexity, as well as the risk of contaminations, is reduced by using these single-use vessels, which facilitate the adoption of GMP conditions (Croughan et al., 2016). With this dynamic culture system, we were able to address several critical issues. First, it allows to easily generate a high number of organoids, which is important for high-throughput applications, attaining around 350 ± 52 (mean $\pm$ SEM) aggregates/mL in the first 24 hours after iPSC seeding at 250 000 cells/mL (**Fig. 1d** and **Supplementary Fig. 1b**). Beyond that, it is important to ensure that the seeding process leads to maximum cell survival and homogeneous aggregate production, since the aggregate size has a critical role in inducing differentiation towards a specific cell lineage (Bauwens et al., 2008). Indeed, a high percentage of cell survival was observed after the single cell seeding, once $54.1 \pm 9.3\%$, $80.7 \pm 2.4\%$ and $88.2 \pm 11.8\%$ of live cells were able to aggregate using three independent human iPSC lines (**Supplementary Fig. 1b**). Moreover, aggregates formed in VWBRs were uniform in size and shape, achieving the optimal diameter (Miranda et al., 2015; Miranda et al., 2016; Silva et al., 2020a) to initiate neural induction at 48 hours after cell seeding (**Fig. 1b-c**). In comparison to static condition, organoids retained a more homogeneous diameter in VWBRs during the differentiation protocol (**Supplementary Fig. 3a-b**), which is useful to reduce variability between multiple experiments.

Cerebellar organoids differentiated in dynamic conditions recapitulate human cerebellar structure.

Using size-controlled human iPSC-derived aggregates and a chemically defined medium, we were able to recapitulate sequential steps of human cerebellar development in a continuous differentiation process, starting with an efficient cerebellar commitment (**Fig. 2**), and further differentiation into different types of cerebellar neurons (**Fig. 3**). By immunostaining and gene expression analysis, we successfully and readily identified distinct types of cerebellar Glutamatergic and GABAergic neurons (**Supplementary Fig. 2a**), as seen in layers of human cerebellar cortex and in cerebellar nuclei. Specifically, the following cell types can be produced in our dynamic culture system: Granule neurons (Pax6$^+$/MAP2$^+$), Unipolar Brush cells (TBR2$^+$/MAP2$^+$), DCN projection neurons (TBR1$^+$/MAP2$^+$), Purkinje cells (Calbindin$^+$/GRID2$^+$), non-Golgi GABAergic interneurons (Calbindin$^-$/Parvalbumin$^+$) and Golgi cells (Neurogranin$^+$/PAX2$^+$) (**Fig. 3a-g**). Furthermore, calcium imaging and electrophysiological evaluation indicate that cerebellar precursors have achieved an efficient maturation in our dynamic cultures (**Fig. 3j-k**). Interestingly, in addition to the functional establishment of neuronal network connectivity, several pools of neural progenitors were maintained until day 80 in culture during the maturation process. The maintenance of a neural progenitor niche during CNS development is an important biological process achieved by the microenvironmental cues, as well as cell-cell interactions, which are capable to balance stem cell

523 quiescence with proliferation and to direct neurogenesis versus gliogenesis (Conover and Notti, 2008). Also, during
524 cerebellar development, different niches of cerebellar progenitor cells are observed, the first in the ventricular zone
525 and the second in the external granule layer (ten Donkelaar et al., 2003; Wingate, 2001). SOX2$^+$ progenitor niche
526 is present in the ventricular zone, where this protein is highly expressed from gestation weeks 20 to 24, being
527 downregulated in the developing human cerebellum, with undetectable expression by week 38 (Pibiri et al., 2016).
528 On the other hand, an external granular layer expressing PAX6 is observed from weeks 20 to 38 of gestation (Pibiri
529 et al., 2016). Therefore, our 3D culture system seems to recreate the *in vivo* microenvironment observed between
530 gestation weeks 20 and 24, supported by the presence of SOX2$^+$ and PAX6$^+$ progenitor niches (**Supplementary**
531 **Fig. 2b-f**).
532
533 **Faster and efficient cerebellar differentiation is promoted by dynamic culture.**
534 The VWBRs allowed us to establish a scalable and efficient system for human iPSC cerebellar commitment, with
535 a homogeneous culture environment inside the vessel and complete suspension of cell aggregates. However, despite
536 the particularly gentle mixing mechanism of the VWBRs, in bioreactor cultures cells are exposed to hydrodynamic
537 shear stress inherent to the suspension culture.
538 As it was already reported that shear stress is an important regulator of germinal specification (Kumar et al., 2017;
539 Wolfe et al., 2012), we analyzed the transcriptional changes occurring during cerebellar differentiation using
540 dynamic conditions and compared with the static control. Evaluating the transcriptomic profiles in the initial steps
541 of cerebellar induction, we detected a more efficient mid-hindbrain commitment, as well as a faster cerebellar
542 differentiation in dynamic conditions (**Fig. 4** and **Supplementary Fig. 3**). The initial mid-hindbrain patterning and
543 further cerebellar induction was achieved by using moderate caudalizing factors, like FGF2 and insulin, which were
544 reported to induce the expression of FGF8 and EN2, crucial transcription factors involved in the isthmic organizer
545 (Chi et al., 2003; Martinez et al., 1999) and mid-hindbrain boundary maintenance (Joyner, 1996). Yoshiki Sasai
546 proposed that this combination can efficiently promote the self-formation of isthmic organizer tissue
547 (OTX2$^+$/EN2$^+$), representing a small area within the organoid (Sasai, 2013). Afterwards, the self-production of
548 signals from this organizer center, like FGF8, stimulate the generation of cerebellar territory (Sasai, 2013). In our
549 dynamic culture, design features of VWBRs (Croughan et al., 2016) provide efficient fluid mixing and enhanced
550 mass transfer within the organoids, promoting a uniform diffusion of signaling molecules, either exogenously
551 provided morphogens or endogenous signals emanating from neighboring cells. A possible explanation for
552 enhanced cerebellar tissue patterning in dynamic conditions may be that iPSC-derived aggregates were exposed to
553 an efficient and uniform diffusion of FGF2 signaling that could result in a larger area of isthmic organizer tissue
554 (OTX2$^+$/EN2$^+$). On the other hand, the maintenance of this organizer tissue is also dependent on the self-production
555 of FGF and WNT signaling, as well as their suppression by inhibitors, in a reaction-diffusion model (Kondo and
556 Miura, 2010; Turing, 1952). Thus, dynamic culture conditions, with more efficient fluid mixing, can lead to uniform
557 exposure to signaling cues and enhance the feedback loops that operate in this self-organized system.
558
559 **Dynamic cerebellar differentiation induces ECM enrichment.**
560 In our time-course data, comparing dynamic and static conditions, we detected that significant ECM enrichment
561 was promoted by using VWBRs for cerebellar differentiation, diverging from the transcriptomic profiles of static
562 condition (**Fig. 5**). Indeed, ECM components are not only highly expressed within neural tissues, but also have a
563 great impact in some aspects of neural development (Jain et al., 2020; Long and Huttner, 2019). With this significant
564 enrichment of ECM in our dynamic cultures, we created a system that avoids the use of exogenous ECM, for
565 instance encapsulation with Matrigel, that is commonly used to support the maintenance of brain organoids in
566 spinner flaks (Lancaster et al., 2012; Qian et al., 2018), being a source of a significant heterogeneity between

567   organoids (Nayler et al., 2020). In our dynamic system, self-derived ECM was enriched in proteoglycans, including
568   aggrecan and versican, as well as a link protein (tenascin C), all of which are highly expressed in neural ECM.
569   Besides that, transcriptomic data analysis of dynamic cultures shows a significant expression of *SULF1* , which
570   supports neurite outgrowth during cerebellar development (Kalus et al., 2015). Other ECM components involved
571   in synaptic processes, neurite outgrowth and axon guidance were highly enriched in dynamic cultures when
572   compared with static, sustaining an efficient neuronal differentiation. In fact, significant changes in ECM during
573   3D differentiation when compared with 2D were already reported, using perfusion stirred-tank bioreactors for iPSC-
574   derived neural progenitor cells (Simão et al., 2018), confirming that 3D culture associated with dynamic conditions
575   may better mimic protein composition as well as the neural microenvironment.
576
577   **Angiogenic process is activated by dynamic culture in cerebellar organoids.**
578   In addition to ECM organization, the analysis of global transcriptional modulation across the differentiation protocol
579   also exposed a significant enrichment of transcripts involved in cell adhesion processes (**Fig. 5**). As expected, most
580   of them were involved in neuronal processes, including axon and neuron projection development. Unexpectedly,
581   not only cell adhesion transcripts involved in neuronal development were enriched in dynamic conditions, but also
582   regulators of circulatory system and vascular development. In fact, previous studies have already shown that shear
583   stress employed early in ESC differentiation favored hematopoietic and endothelial fates (Wolfe and Ahsan, 2013).
584   Besides that, the application of shear stress to endothelial cells stimulates the expression of VEGFR2, resulting in
585   increased endothelial cell survival (dela Paz et al., 2012). This may explain the presence of transcripts associated
586   with angiogenic fate upon mechanical stimulation. ECM plays a crucial role in the regulation of the angiogenic
587   process, and the proangiogenic effect of some ECM molecules and fragments (Neve et al., 2014; Stupack and
588   Cheresh, 2002), including Collagen and laminin subtypes, fibronectin and tenascin-C, have been shown.
589   Interestingly, our transcriptomic analysis revealed that the increased expression of ECM components during
590   cerebellar differentiation was complemented by higher expression of transcripts involved in sprouting angiogenic
591   processes (**Fig. 6c**), which was confirmed by co-localization of ECM components and CD31[+]/CD34[+] endothelial
592   cells (**Fig. 6d**). To investigate a possible origin of this angiogenic process in our dynamic cultures, we analyzed
593   three different mechanisms that could activate angiogenesis: ECM signaling, response to mechanical stimulus and
594   cellular response to hypoxia (Pugh and Ratcliffe, 2003). Hypoxia-based is unlikely, since no differences were found
595   in the expression of transcripts involved in the cellular response to hypoxia between static and dynamic
596   differentiations (**Fig. 6e**). Moreover, HIF1α pathway transcripts were included in the top 100 genes downregulated
597   in dynamic conditions comparatively to the static ones (**Supplementary Fig. 5e**). Therefore, two different
598   mechanisms may be responsible for promoting the angiogenic process in our dynamic cultures: one related with
599   ECM organization and the other with cellular response to mechanical stimulus (**Fig. 6f**). In the CNS, angiogenesis
600   is promoted by VEGF-independent signaling, activated by the expression of NPR1 (Tata et al., 2015). NPR1,
601   neuropilin-1, is a non-catalytic transmembrane protein, which was originally identified as an adhesion molecule in
602   the CNS (Takagi et al., 1995) and seems to have an essential role in the vascularization of the hindbrain (Gerhardt
603   et al., 2004). NPR1 was reported to enforce ECM signaling (Raimondi, 2014), in which the extracellular protein
604   domain complexes with integrins, promotes the recruitment of ABL1 and enables CDC42-actin rearrangement
605   independently of VEGF stimulation (**Fig. 6f**), promoting angiogenesis (Fantin et al., 2015; Raimondi et al., 2014).
606   On the other hand, mechano-transduction signaling is also responsible for mediating the angiogenic process in a
607   VEGF-dependent manner (**Fig. 6f**). KLF2 is one of many vasoactive endothelial genes that suffer transcriptional
608   modulation during embryonic development after the establishment of fluid flow (Lee et al., 2006). Moreover, it was
609   demonstrated that shear-stress-induced VEGF expression is mediated by KLF2 expression (dela Paz et al., 2012)
610   and its expression mirrors the rise of fluid shear stress across development *in vivo* (Lee et al., 2006). Overexpression

611 of KFL2 was reported to promote angiogenesis through the upregulation of EGFL7 (Renz et al., 2015), which was
612 found expressed in the vasculature (Parker et al., 2004). Thus, we analyzed the expression of these two different
613 angiogenic inductors, NFR1 and KLF2, to unveil the contribution of ECM remodeling and mechano-transduction
614 signaling, in addition to VEGFA, to confirm whether angiogenesis was promoted by either an independent or
615 dependent-VEGF signaling. Our data show that a possible combination of these two different signaling pathways
616 could contribute for the angiogenesis enhancement observed in our dynamic culture. Significant differences of
617 *NFR1* and *KLF2* transcript expression were found between static and dynamic conditions, with higher mRNA levels
618 presented in dynamic conditions until day 35 (**Fig. 6g**), along with a significant expression of *VEGFA* in dynamic
619 culture-derived organoids from day 14 to 80 of differentiation (**Fig. 6h**). We hypothesize that this combined effect
620 observed in dynamic conditions may be important for the higher degree of neuronal maturation present in our
621 cerebellar organoids (**Fig. 6i**).

Conclusion

624 In conclusion, we have reported here the successful and efficient scalable generation of cerebellar organoids,
625 demonstrated by the transcriptomic profile during differentiation. The transcriptomic signatures under dynamic
626 culture conditions revealed significant ECM organization that can better mimic the neural microenvironment and
627 maintain the organoids healthy for at least 80 days of differentiation. One current limitation for the generation of
628 brain organoids has been the recapitulation of a complex microenvironment that involves interaction between
629 different cell types, including vascular cells, neurons, astrocytes, oligodendrocytes and microglia. Here, we
630 demonstrated that dynamic culture can activate signaling pathways important to induce the angiogenic process
631 during neural commitment, introducing significant cues for the recapitulation of a more complex tissue, comprising
632 different cell types. Additionally, this dynamic system allows increased reproducibility between experiments and
633 the possibility of further upscaling the production of cerebellar organoids. Bioreactor technology also has the
634 potential to allow further improvements to the system here described, namely automated monitoring and control of
635 the culture environment (eg. pH or dissolved oxygen concentration) or the use of alternative culture medium feeding
636 strategies such as perfusion (Kropp et al., 2016). We expect that the methodologies developed here will widen the
637 applicability of cerebellar organoids in high-throughput screening, including drug and toxicological testing, as well
638 as in the study of important aspects of pathological pathways involved in cerebellar dysfunction.

Figure 1. Neural commitment in human iPSC-derived aggregates using VWBRs. a, Schematic for cerebellar differentiation of human iPSC-derived aggregates using VWBR (see also Methods for details). **b,** Distribution of floating aggregates diameters and representative bright field photomicrographs at days 1, 2 and 5 of differentiation, demonstrating that homogeneous size and shape aggregates were obtained from different human iPSC lines using VWBRs. **c,** Diameter of iPSC-derived aggregates along the cerebellar differentiation using different human iPSC lines. **d,** Number of iPSC-derived aggregates from day 1 to day 35 of cerebellar differentiation. Points show the mean of 3 independent differentiation experiments using 3 different iPSC lines and the area fill represents SEM (see also Supplementary Fig. 1 for more details). **e,** Total volume of biomass relative to day 1. Points show the mean of 3 independent differentiation experiments using 3 different iPSC lines and the area fill represents SEM (see also Supplementary Fig. 1 for more details). **f,** qRT-PCR analyses of aggregates derived from different iPSC lines at the indicated time-points. Box-plots diagrams depict mRNA expression levels ($2^{-\Delta CT}$) relative to *GAPDH*. Each color and shape-coded dot represents data from one experiment. One-way ANOVA (Kruskal-Wallis test), *p<0.05, **p<0.01, ***p<0.001; error bars represent SEM. **g,** Immunofluorescence for NESTIN, PAX6, NCAD and SOX2 on days 7 and 14 of differentiation. Scale bars, 50μm.

932
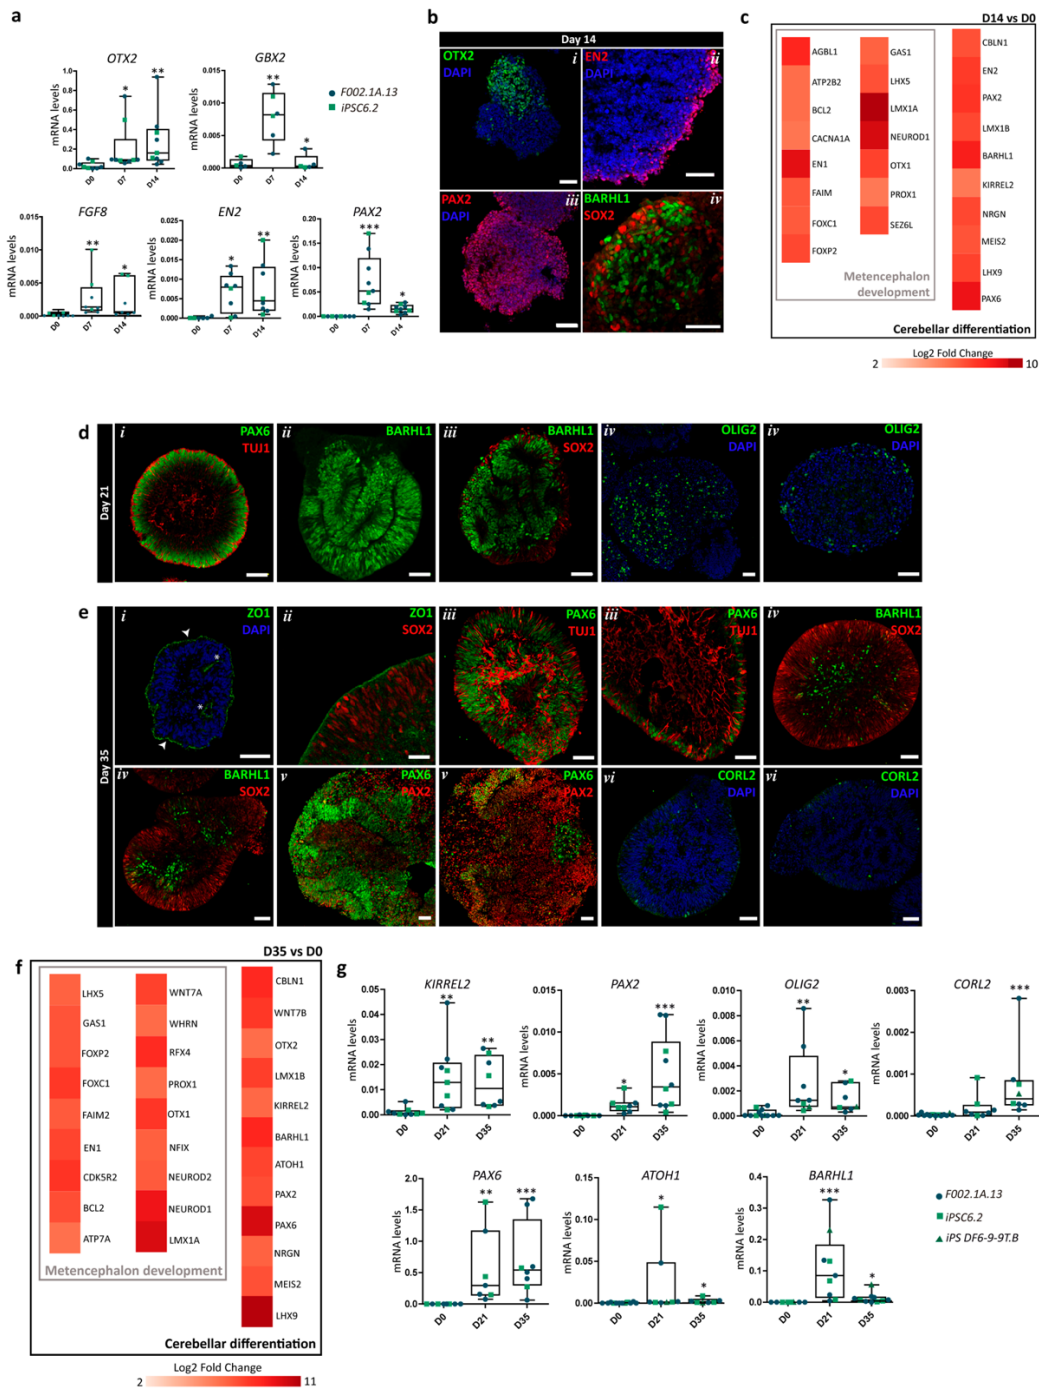

933
934 **Figure 2. Efficient cerebellar commitment and differentiation in human iPSC-derived aggregates using VWBRs. a,** qRT-PCR analysis
935 of aggregates derived from different human iPSC lines at the indicated time-points. Box-plots diagrams depict mRNA expression levels ($2^{-\Delta CT}$)
936 relative to *GAPDH*. Each color and shape-coded dot represents data from one differentiation experiment. One-way ANOVA (Kruskal-
937 Wallis test), *p<0.05, **p<0.01, ***p<0.001; error bars represent SEM. **b,** Immunofluorescence analysis on day 14 of differentiation for
938 OTX2, EN2, PAX2, BARHL1 and SOX2. Scale bars, 50μm. **c,** Heatmap highlighting genes differentially expressed (Log2 FC > 2 and
939 adjusted p-value < 0.05) related with metencephalon development and cerebellar differentiation for day 14 vs day 0 of differentiation. **d and
940 e,** Immunostaining analysis on days 21 and 35 of differentiation for the indicated markers. Scale bars, 50μm. **f,** Heatmap highlighting genes
941 differentially expressed (Log2 FC > 2 and adjusted p-value < 0.05) related with metencephalon development and cerebellar differentiation
942 for day 35 vs day 0 of differentiation. **g,** qRT-PCR analysis of 3D cultures derived from different human iPSC lines at the indicated time-
943 points. Box-plots diagrams depict mRNA expression levels ($2^{-\Delta CT}$) relative to *GAPDH*. Each color and shape-coded dot represents data from
944 one differentiation experiment. One-way ANOVA (Kruskal-Wallis test), *p<0.05, **p<0.01, ***p<0.001; error bars represent SEM.
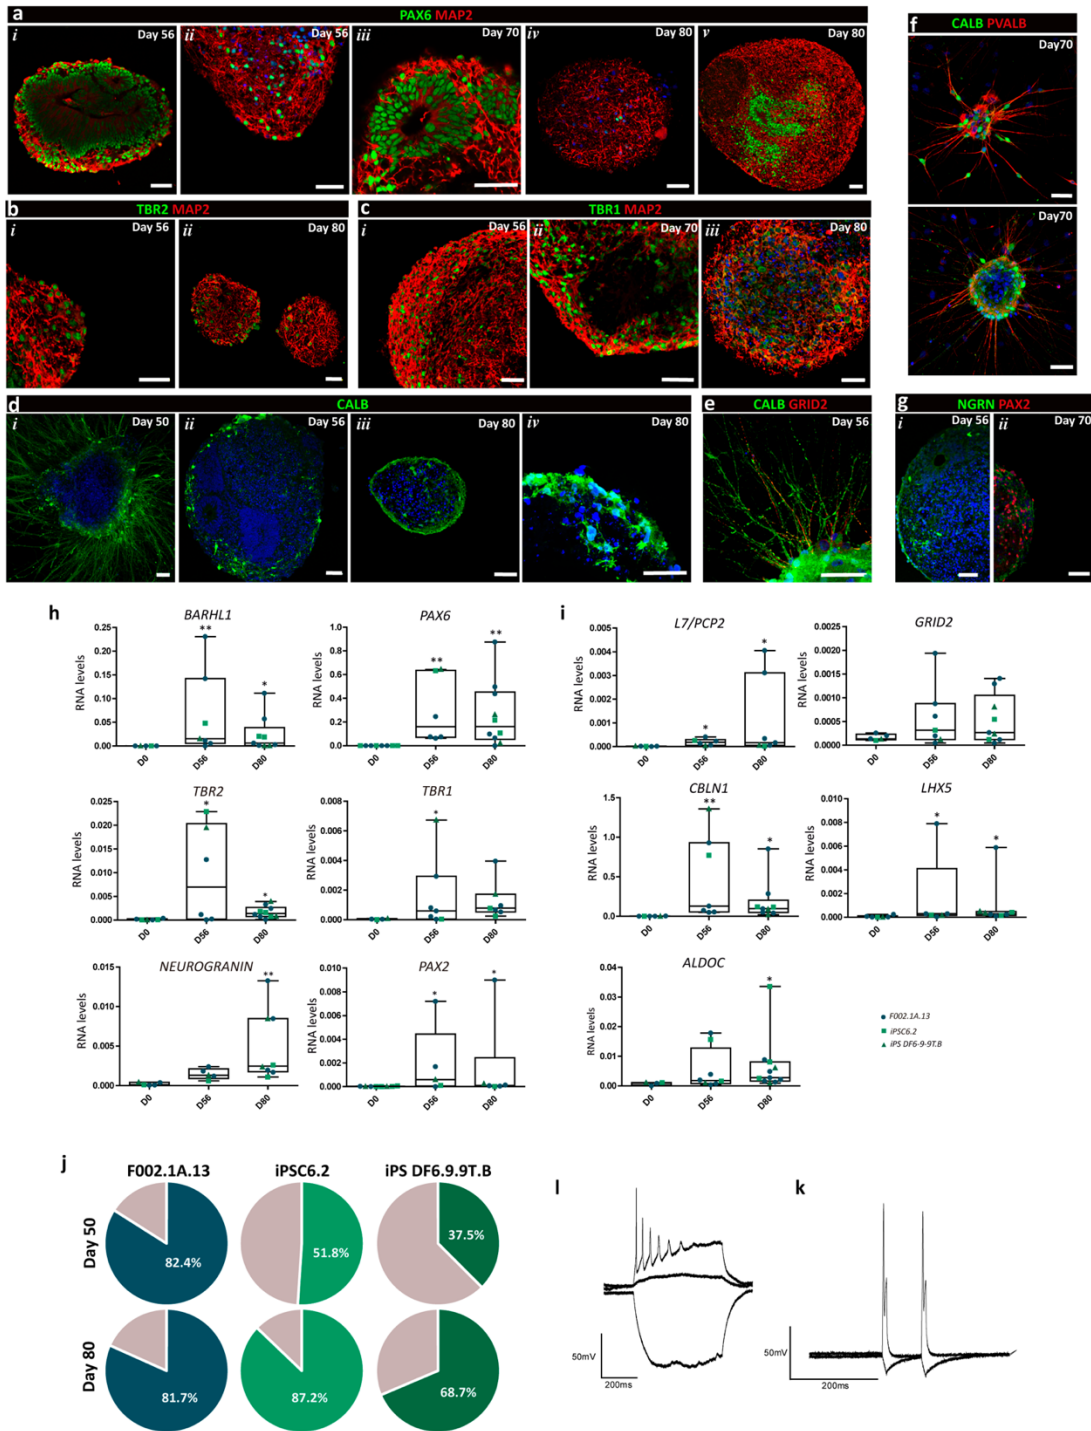

945

Figure 3. Different types of functional cerebellar neurons in human iPSC-derived aggregates. a-g, Immunofluorescence of distinct proteins (as indicated at the bottom of each image) on indicated time-points of differentiation. Scale bars, 50μm. **h-i,** qRT-PCR analysis of aggregates derived from different human iPSC lines at the indicated time-points for markers of different types of cerebellar neurons, including Purkinje cell markers (i). Box-plots diagrams depict mRNA expression levels ($2^{-\Delta CT}$) relative to *GAPDH*. Each color and shape-coded dot represents data from one differentiation experiment. One-way ANOVA (Kruskal-Wallis test), *p<0.05, **p<0.01, ***p<0.001; error bars represent SEM. **j,** Percentage of neurons, displaying a histamine/KCl response ratio below 0.8, is shown in colored slices. **l-k,** Whole path-clamp recording on day 80 of differentiation. Representative traces of firing response evoked by a 500 ms current pulse (l) and firing responses to two independent current injections (10 ms) separated by 80 ms (k).

983 **conditions when compared with static protocol. a,** Top gene ontology (GO) biological processes terms identified for the differentially up-
984 regulated genes (Log2 FC > 2 and adjusted p-value < 0.05) of dynamic versus static conditions in cerebellar differentiation. **b,** Volcano Plot
985 of differentially expressed genes between dynamic and static conditions showing significantly up-regulated transcripts in dynamic conditions
986 (Log2 FC > 2 and adjusted p-value < 0.05) annotated in the ECM organization process (GO:0030198). **c,** Immunostaining analysis on days
987 35 of differentiation in dynamic conditions for the indicated ECM markers. Scale bars, 50µm. **d,** Volcano Plot of differentially expressed
988 genes between dynamic and static conditions showing significantly up-regulated genes in dynamic conditions (Log2 FC > 2 and adjusted p-
989 value < 0.05) annotated in the cell adhesion process (GO:0007155).
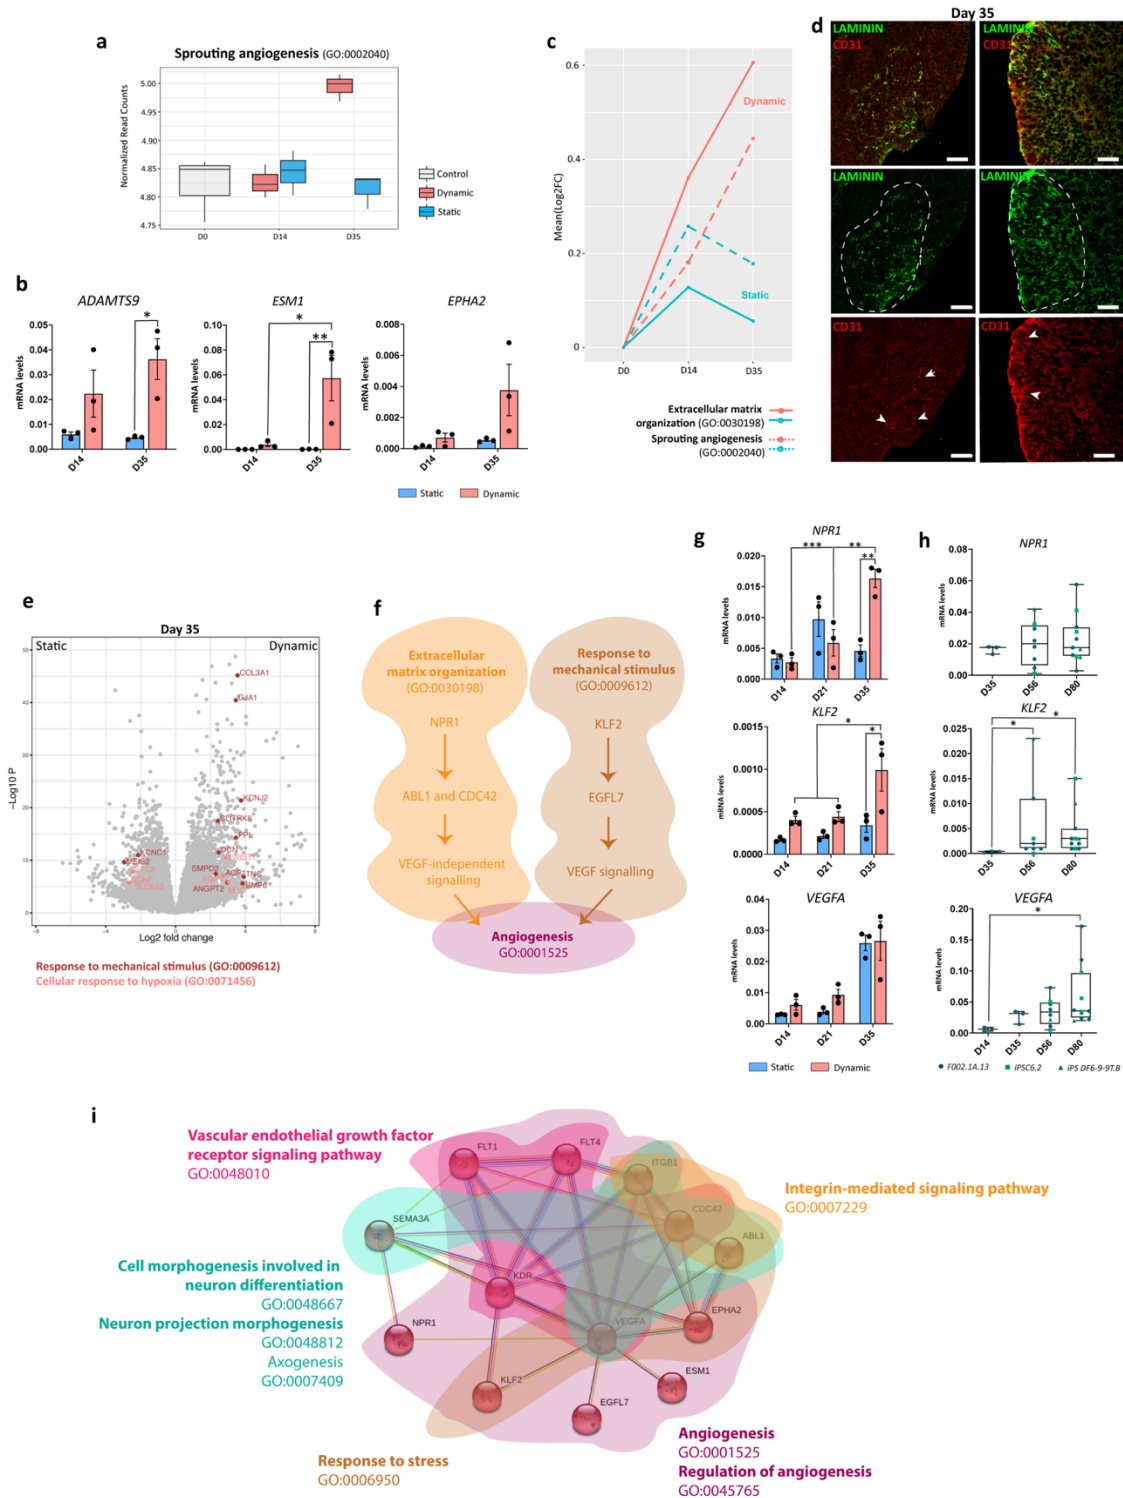

Figure 6. Dynamic condition modulates the expression levels of genes that favor the angiogenesis onset. a, Box-plot representing RNA-seq normalized read counts of representative genes annotated in the sprouting angiogenesis process (GO:0002040, n=125 genes) for control (day 0), dynamic and static conditions at indicated time-points of differentiation. **b,** qRT-PCR analyses of organoids derived from F002.1A.13 iPSC line for genes involved in angiogenesis process. Diagrams depict mRNA expression levels ($2^{-\Delta CT}$) relative to GAPDH based on three independent differentiation experiments for each condition. Two-way ANOVA (Tukey's multiple comparisons test), *p<0.05, **p<0.01; error bars represent SEM. **c,** Line plot representing the expression of representative transcripts annotated in ECM organization (GO:0030198,

998   n=240 genes) and sprouting angiogenesis (GO:0002040 n=125 genes) processes for static and dynamic conditions relative to day 0. **d,**
999   Immunofluorescence for LAMININ and CD31 on day 35 of dynamic differentiation. Scale bars, 50μm. **e,** Volcano Plot of differentially
1000   expressed genes between dynamic and static conditions showing significantly down- and up-regulated transcripts in dynamic conditions
1001   (|Log2 FC| > 2 and adjusted p-value < 0.05) related with response to mechanical stimulus (GO:0009612, n=180 genes) and cellular response
1002   to hypoxia (GO:0071456, n=180 genes) processes. **f,** Schemes illustrating the proposed networks that may be involved in the modulation of
1003   angiogenic process by either independent or dependent-VEGF signaling pathway. **g,** qRT-PCR analyses of organoids derived from
1004   F002.1A.13 iPSC line. Diagrams depict mRNA expression levels ($2^{-\Delta CT}$) relative to GAPDH based on three independent differentiation
1005   experiments for each condition. Two-way ANOVA (Tukey's multiple comparisons test), *p<0.05, **p<0.01; error bars represent SEM. **h,**
1006   qRT-PCR analysis of organoids derived from different human iPSC lines at the indicated time-points. Box-plots diagrams depict mRNA
1007   expression levels ($2^{-\Delta CT}$) relative to GAPDH. Each color and shape-coded dot represents data from one differentiation experiment. One-way
1008   ANOVA (Kruskal-Wallis test), *p<0.05; error bars represent SEM. **i,** Protein-protein interaction network prediction based on protein
1009   encoding genes involved in angiogenic process. Interaction networks were obtained from STRING database, in which nodes were clustered
1010   using Markov Cluster Algorithm (MLC) with an inflation parameter = 3. Biological processes (FDR < 0.05) annotating the analyzed proteins
1011   are highlighted.

Table 2. List of primary antibodies and dilutions used for immunostaining

Antibody	Host species	Company	Dilution
AGGRECAN	Mouse	Invitrogen	1:200
BARHL1	Rabbit	Atlas	1:500
CALBINDIN	Rabbit	Rabbit	1:500
CD31	Mouse	DAKO	1:100
CD34	Mouse	BD Pharmingen	1:100
COLLAGEN I	Rabbit	Abcam	1:200
CORL2	Rabbit	Novus Biological	1:100
EN2	Mouse	Sigma	1:200
FIBRONECTIN	Mouse	Abcam	1:1000
GRID2	Mouse	Santa Cruz	1:100
KI67	Rabbit	Abcam	1:100

LAMININ	Rabbit	Abcam	1:200
MAP2	Mouse	Sigma	1:500
NCAD	Mouse	BD Transduction	1:500
NESTIN	Mouse	R&D Systems	1:400
NRGN	Rabbit	Millipore	1:200
OLIG2	Rabbit	Millipore	1:500
OTX2	Rabbit	Abcam	1:200
PAX2	Mouse	Abnova	1:400
PAX6	Rabbit	Covance	1:400
PVALB	Mouse	Sigma	1:200
SOX2	Mouse	R&D Systems	1:200
SYNAPSIN	Rabbit	Abcam	1:200
TBR1	Rabbit	Millipore	1:200
TBR2	Rabbit	Abcam	1:200
TUJ1	Mouse	Biolegend	1:500
VERSICAN	Mouse	Invitrogen	1:100
ZO1	Rabbit	Novex	1:100
