1 Abstract

2 DNA barcodes are a useful tool for discovering, understanding, and monitoring biodiversity 3 which are critical at a time when biodiversity loss is a major problem for many countries. 4 However, widespread adoption of barcodes requires cost-effective and simple barcoding 5 methods. We here present a workflow that satisfies these conditions. It was developed via 6 "innovation through subtraction" and thus requires minimal lab equipment, can be learned 7 within days, reduces the barcode sequencing cost to <10 cents, and allows fast turnaround 8 from specimen to sequence by using the real-time sequencer MinION. We first describe 9 cost-effective and rapid procedures for obtaining tagged amplicons. We then demonstrate 10 how a portable MinION device can be used for real-time sequencing of tagged amplicons in 11 many settings (field stations, biodiversity labs, citizen science labs, schools). Small projects 12 can use the flow cell dongle ("Flongle") while large projects can rely on MinION flow cells 13 that can be stopped and re-used after collecting sufficient data for a given project. We also 14 provide amplicon coverage recommendations that are based on several runs of MinION flow 15 cells (R10.3) which suggest that each run can generate >10,000 barcodes. Next, we present 16 a novel software, ONTbarcoder, which overcomes the bioinformatics challenges posed by 17 the sequencing errors of MinION reads. This software is compatible with Windows10, 18 Macintosh, and Linux, has a graphical user interface (GUI), and can generate thousands of 19 barcodes on a standard laptop within hours based on two input files (FASTQ, demultiplexing 20 file). We document that MinION barcodes are virtually identical to Sanger and Illumina 21 barcodes for the same specimens (>99.99%). Lastly, we demonstrate how rapidly MinION 22 data have improved by comparing the performance of sequential flow cell generations. We 23 overall assert that barcoding with MinION is the way forward for government agencies, 24 universities, museums, and schools because it combines low consumable and capital cost 25 with scalability. Biodiversity loss is threatening the planet and the use of MinION barcodes 26 will help with enabling an army of researchers and citizen scientists, which is necessary for 27 effective biodiversity discovery and monitoring.

28

29 **1. Background**

30 DNA sequences have been used for identification and taxonomic purposes for decades 31 (Hebert, Cywinska et al. 2003, Tautz, Arctander et al. 2003, Meier 2008), but for most of this 32 time been akin to mobile phones in the 1990s: of limited value due to sparse signal coverage 33 and high cost. Obtaining barcodes was problematic due largely to the complicated and 34 expensive procedures on which it relied. Some of these problems have since been 35 addressed by, for example, developing effective DNA extraction protocols and optimizing 36 Sanger sequencing procedures (Ivanova, Dewaard et al. 2006, Ivanova, Borisenko et al. 37 2009). These improvements enabled the establishment of a centralized barcoding facility in 38 2006. After 15 years and the investment of >200 million USD, ca. 8 million animal barcodes 39 are available for searches on BOLD Systems, but only ca. 6 million are in the public domain 40 (http://boldsystems.org/index.php/IDS_OpenIdEngine). Combined with barcodes from NCBI 41 GenBank, they are now a valuable resource to the global biodiversity community. However, the cost of barcodes has remained high (http://ccdb.ca/pricing/) and the prevalent approach 42 43 for sizeable projects is sending specimens from all over the world to one center and then 44 only some back to the country of origin. This interferes with real-time biodiversity monitoring 45 and specimen accessibility. We therefore argue that access to barcodes has to be 46 democratized through decentralization. We here show that this achievable because the 47 application of a technique that is known as "innovation through subtraction" in engineering 48 readily yields simplified and cost-effective solutions for DNA barcoding and the amplification 49 and sequencing of a short mitochondrial COI fragment can be efficiently performed 50 anywhere and by biologists and citizen scientists alike.

51

A decentralized model for monitoring the world's biodiversity is necessary given the scale, urgency, and importance of the task at hand. For example, even if there were only 10 million species of metazoan animals on the planet (Stork, McBroom et al. 2015) and a new species is discovered with every 50th specimen that is processed, species discovery with barcodes will require the sequencing of 500 million specimens (Yeo, Srivathsan et al. 2020). Yet,

species discovery is only a small part of the biodiversity challenge in the 21st century. 57 58 Biodiversity loss is now considered by the World Economic Forum as one of the top three 59 global risks based on likelihood and impact for the next 10 years (World Economic Forum 60 2020) and Swiss Re estimates that 20% of all countries face ecosystem collapse as 61 biodiversity declines (Swiss Re 2020). Biodiversity loss is no longer just an academic 62 concern; it is now a major threat to human communities and the health of the planet. This 63 also implies that biodiversity discovery and monitoring require completely different scales 64 than in the past. The old approaches thus need rethinking because all countries need real-65 time distributional and abundance information to develop effective conservation strategies 66 and policies. In addition, they need information on how species interact with each other and 67 the environment (Abrego, Roslin et al. 2021). Many of these biodiversity monitoring and 68 environmental management activities have to focus on terrestrial invertebrates, whose 69 biomass surpasses that of all terrestrial vertebrates combined (Bar-On, Phillips et al. 2018) 70 and who occupy a broad range of ecological guilds. The main obstacles are high numbers of 71 specimens and species and the rapid decline of many of these taxa (Bell, Blumgart et al. 72 2020, Eisenhauer, Bonn et al. 2019, Hallman, Sorg et al. 2017, Hallman, Ssymank et al. 73 2021, Stepanian, Entrekin et al. 2020, Wagner, Grames et al. 2021) which means that 74 monitoring should be locally conducted to allow for rapid turnaround. This requires simple 75 and cost-effective procedures that can be implemented anywhere by stakeholders with very 76 different scientific and skill backgrounds.

77

DNA barcoding was proposed at a time when biodiversity loss was not on the radar of
economists. Instead, barcodes were initially intended as an identification tool for biologists
(Hebert, Cywinska et al. 2003). Thus, most projects focused on taxa with a large following in
biology (e.g., birds, fish, butterflies) (Kwong, Srivathsan et al. 2012). However, this also
meant that these projects only covered a small proportion of the terrestrial animal biomass
(Bar-On, Phillips et al. 2018) and species-level diversity (Groombridge 1992). Yet, despite
targeting taxa with well-understood diversity, the projects struggled with covering >75% of

85 the described species in these groups (Kwong, Srivathsan et al. 2012). When the pilot 86 barcoding projects ran out of material from identified specimens, they started targeting 87 unidentified specimens; i.e., DNA barcoding morphed into a technique that was used for 88 biodiversity discovery ("dark taxa": Page 2011, Kwong, Srivathsan et al. 2012). This shift 89 towards biodiversity discovery was gradual and incomplete because the projects used a 90 "hybrid approach" that started with subsampling or sorting specimens to "morphospecies" 91 before barcoding representatives of each morphospecies/sample (e.g., Barrett and Hebert 92 2005, Hendrich, Pons et al. 2010, Hebert, DeWaard et al. 2013, Ng'endo, Osiemo et al. 93 2013, Hebert, Ratnasingham et al. 2016, Thormann, Ahrens et al. 2016, Knox, Hogg et al. 94 2020). This is problematic, as morphospecies sorting is known to be labour-intensive and of 95 unpredictable quality because it is heavily dependent on the taxonomic expertise of the 96 sorters (Krell 2004, Stribling, Pavlik et al. 2008). Thus, such hybrid approaches are of limited 97 value for obtaining reliable quantitative data on biodiversity, but were adopted as a 98 compromise owing to the prohibitive cost of barcoding. The logical alternative is to barcode 99 all specimens and then group them into putative species based on sequence information. 100 Such a "reverse workflow" (Wang, Srivathsan et al. 2018), where every specimen is 101 barcoded as the initial pre-sorting step, yields quantitative data and corroborated species-102 level units. However, the reverse workflow requires efficient and low-cost barcoding methods 103 that are also suitable for biodiverse countries with limited science funding.

104

105 Fortunately, such cost-effective barcoding methods are now becoming available. This is 106 partially due to the replacement of Sanger sequencing with second- and third-generation 107 sequencing technologies that have lowered sequencing costs dramatically (Shokralla, Spall 108 et al. 2012, Shokralla, Porter et al. 2015, Meier, Wong et al. 2016, Hebert, Braukmann et al. 109 2018, Krehenwinkel, Kennedy et al. 2018, Srivathsan, Baloglu et al. 2018, Wang, Srivathsan 110 et al. 2018, Srivathsan, Hartop et al. 2019, Yeo, Srivathsan et al. 2020). Such changes mean 111 that the reverse workflow is now available for tackling the species-level diversity of those 112 metazoan clades that are so specimen- and species-rich that they have been neglected in

113 the past (Ponder and Lunney 1999, Srivathsan, Hartop et al. 2019). Many of these clades 114 have high spatial species turnover, requiring many localities in each country to be sampled 115 and massive numbers of specimens to be processed (Yeo, Srivathsan et al. 2020). Such 116 intensive processing is best achieved close to the collecting locality to avoid the 117 unnecessary risks, delays and costs from shipping biodiversity samples across continents. 118 This is now feasible because biodiversity discovery can be readily pursued in decentralized 119 facilities at varied scales. Indeed, accelerated biodiversity discovery is a rare example of a 120 big science initiative that allows for meaningful engagement of students and citizen scientists 121 and can in turn significantly enhance biodiversity education and appreciation (Pomerantz, 122 Peñafiel et al. 2018, Watsa, Erkenswick et al. 2020). This is especially so when stakeholders 123 not only barcode, but also image specimens, determine species abundances, and map 124 distributions of newly discovered species. All of which can be based on specimens collected 125 in their own backyard.

126

127 But can such decentralized biodiversity discovery really be effective? Within the last five 128 years, the students and interns in the laboratory of the corresponding author at the National 129 University of Singapore barcoded >330,000 specimens. After analyzing the first >140,000 130 barcoded specimens for selected taxa representing different ecological guilds, the alpha and 131 beta diversity of Singapore's arthropod fauna was analyzed based on ~8,000 putative 132 species which revealed that some habitats were unexpectedly species-rich and harboured very unique faunas (e.g., mangroves, freshwater swamp: Yeo, Srivathsan et al. 2020; 133 134 Baloğlu, Clews et al. 2018). Barcodes even helped with the conservation of charismatic taxa 135 when they were used to identify the larval habitats for more than half of Singapore's damsel-136 and dragonfly species (Yeo, Puniamoorthy et al. 2018) and facilitated species interaction 137 research and biodiversity surveys based on eDNA (Lim, Tay et al. 2016, Srivathsan, 138 Nagarajan et al. 2019). Biodiversity appreciation by the public was fostered by featuring 139 newly discovered species and their species interactions on "Biodiversity of Singapore" (BOS 140 >15,000 species: <u>https://singapore.biodiversity.online/</u>) and dozens of new species have

141	been described and the descriptions of another 150 species are being finalized (Grootaert
142	2018, Tang, Grootaert et al. 2018, Tang, Yang et al. 2018, Wang, Yamada et al. 2018,
143	Wang, Yong et al. 2018, Grootaert 2019, Ismay and Ang 2019, Samoh, Satasook et al.
144	2019, Wang, Yamada et al. 2020).
145	
146	2. Methods for the democratization of DNA barcoding through simplification
147	Barcoding a metazoan specimen requires the successful completion of three steps: (1)
148	obtaining DNA template, (2) amplifying COI via PCR, and (3) sequencing the COI amplicon.
149	Many biologists learn these techniques in university for a range of different genes – from
150	those that are easy to amplify (short fragments of ribosomal and mitochondrial genes with
151	well-established primers) to those are difficult (long, single-copy nuclear genes with few
152	known primers). Fortunately, amplification of short mitochondrial markers like COI does not
153	require the same level of care as nuclear markers. Learning how to barcode efficiently is
154	hence an exercise of unlearning by applying "innovation through subtraction". Note that this
155	unlearning is of critical importance for the democratization of biodiversity discovery with DNA
156	barcodes and is particularly vital for boosting biodiversity research where it is most needed:
157	in biodiverse countries with limited science funding.
158	
159	In this section, we first briefly summarize commonly used procedures for DNA extraction,
160	PCR, and sequencing. For each step we then describe how the procedures can be
161	simplified. In addition to the description, we provide videos for the described procedures
162	which are available from the YouTube channel "Integrative Biodiversity Discovery"

163 (https://www.youtube.com/channel/UC1WowokomhQJRc71FmsUAcg). Note that all

techniques have been extensively tested in our lab, primarily on invertebrates preserved in

165 ethanol. Regarding sequencing, we briefly introduce four methods, but our focus is on

166 MinION sequencing because this device is particularly suitable as the default sequencing

167 option for decentralized biodiversity discovery.

168

169 Methods for step 1: Obtaining DNA template

170	Most biologists learn that DNA extraction requires tissue digestion, DNA purification, and
171	DNA elution. This approach is slow and expensive because it frequently involves kits and
172	consumables that are designed for obtaining the kind of high-quality DNA that is needed for
173	amplifying "difficult" genes (e.g., long, single-copy nuclear markers). However COI is a
174	mitochondrial gene and thus naturally enriched. Indeed, the tiny mitochondrial genome (16
175	kbp) usually contributes 0.5-5% of the DNA in a genomic extraction (Arribas, Andújar et al.
176	2016, Crampton-Platt, Yu et al. 2016). Furthermore, barcoding requires only the
177	amplification of one short marker (<700 bp) so that not much DNA template is needed. This
178	allows for using the following simplified procedures that are designed for specimens
179	containing DNA template of reasonable quality (e.g., Malaise trap specimens collected within
180	the last 20 years).
181	
182	Simplified DNA "extraction": Obtaining template for DNA barcoding need not take more than

183 20 minutes, does not require DNA purification, and costs essentially nothing. The cheapest, 184 but not necessarily fastest, method is "directPCR"; i.e., deliberately "contaminating" a PCR 185 reaction with the DNA of the target organism by adding the entire specimen or a tissue 186 sample into the PCR reagent mix (Wong, Tay et al. 2014). This method is very fast and 187 effective for small specimens lacking thick cuticle or skin (Wong, Tay et al. 2014) and works 188 particularly well for many abundant aquatic invertebrates such as chironomid midges and 189 larvae. Larger specimens require the use of body parts [leg or antenna: Wong, Tay et al. 190 (2014)]. Such dissections tend to be labour-intensive if large numbers of specimens must be 191 processed, but it is a good method for small numbers of samples or in barcoding 192 experiments that are carried out in poorly equipped labs. Note that the whole body or body 193 part that is used for directPCR can be recovered after amplification, although soft-bodied 194 animals may become transparent.

195

196 An alternative to directPCR is buffer-based DNA extraction. This method is also essentially 197 cost-free because it involves alkaline buffers that are inexpensive, usually available in 198 molecular labs (e.g., PBS), or can be prepared easily (HotSHOT) (Truett, Heeger et al. 2000, Thongjued, Chotigeat et al. 2019)). Our preferred method is extraction with HotSHOT, which 199 200 we have used for barcoding >50,000 arthropods (Yeo, Srivathsan et al. 2020). We use 10-15 201 µL HotSHOT per specimen. Small specimens are submerged within the well of a microplate 202 while larger specimens are placed head-first into the well. The tissue need not be entirely 203 submerged in HotSHOT. DNA is obtained within 20 minutes in a thermocycler via two 204 heating steps (Truett, Heeger et al. 2000). After neutralization, >20 µl of template is available 205 for amplifying COI and the voucher can be recovered. Note that HotSHOT extraction leaves 206 most of the DNA in the specimen untouched and more high quality DNA can subsequently 207 be extracted from the same specimen. An alternative to obtaining DNA via lab buffers is the 208 use of commercial DNA extraction buffers (Kranzfelder, Ekrem et al. 2016). These buffers 209 have a longer shelf life, and are good alternatives for users who only occasionally barcode 210 moderate numbers of specimens. In the past, we have used QuickExtract (Srivathsan, 211 Hartop et al. 2019) and found that 10 µl is sufficient for obtaining DNA template from most 212 insect specimens. In summary, obtaining DNA templates for barcoding is fast and 213 straightforward and most published barcoding studies greatly overcomplicate this step. It 214 should be noted however, that all DNA extraction methods require the removal of excess 215 ethanol from specimens prior to extraction (e.g., by placing the specimen on tissue paper or 216 replacing ethanol with water prior to specimen processing) and that the DNA extracts 217 obtained with such methods should be stored at -20°C and be used within days. 218

219 <u>Methods for step 2: amplifying *COI* via PCR</u>. Most PCR recipes and reagents are optimized 220 to work for a wide variety of genes and not just for a gene like the *COI* barcode that is 221 naturally enriched, has a large number of known primers, and is fairly short. Standard PCR 222 recipes can therefore be simplified. However, the use of "modern" sequencing technologies 223 such as Illumina, PacBio, or Oxford Nanopore Technologies introduces one complication:

224 The amplicons have to be "tagged" (or "indexed"/"barcoded"). This is necessary because

225 pools of amplicons are sequenced simultaneously instead of processing one amplicon at a

time (as in Sanger sequencing). Tags are specimen identifiers consisting of short DNA

sequences at the 5' ends of the amplicons. They allow for the assignment of each sequence

228 read obtained during sequencing to a specific specimen in the "demultiplexing"

- bioinformatics step. Numerous tagging techniques have been described in the literature, but
- 230 most are too complicated for efficient DNA barcoding.
- 231
- 232 Simplified techniques for obtaining tagged amplicons

233 Published protocols tend to have five issues that increase workload and/or inflate cost, while

- a fifth issue only affects amplicon tagging:
- Issue 1: expensive polymerases or master mixes.

These often utilize high-fidelity polymerases that are designed for amplifying low copy-

237 number nuclear genes based on low-concentration template but rarely make a difference

when amplifying COI. Indeed, even home-made polymerases can be used for barcoding.

239 This is important because high import taxes for consumables interfere with biodiversity

240 discovery in many biodiverse countries.

• Issue 2: indiscriminate use of single-use consumables.

242 Disposable products increase costs and damage the environment. Most biodiversity

samples are obtained under "unclean conditions" that create numerous opportunities for

cross-specimen contamination long before specimens reach the lab (e.g., thousands of

specimens rubbing against each other in sample containers and in the same

246 preservation fluid). Yet numerous studies have shown that the DNA from specimens

- 247 exposed to such conditions will usually outcompete contaminant DNA that is likely to
- occur at much lower concentrations. Similarly, the probability that a washed/flushed and
- 249 autoclaved microplates or pipette tips retain enough viable contaminant DNA to
- successfully outcompete the template DNA is extremely low. Indeed, we have repeatedly
- tried and failed to amplify COI using reused plastic consumables and water as template.

252		That it is safe to reuse some consumables is again good news for biodiversity discovery
253		under severe financial constraints. Note, however, that we do not recommend the re-use
254		of consumables for handling stock chemicals such as primers and sequencing reagents.
255	•	Issue 3: large PCR volumes (25-50 μl).
256		Pools of tagged amplicons comprise hundreds or thousands of products and there is
257		typically more than enough DNA for preparing a library. Accordingly, even small PCR
258		volumes of 10-15 μI are sufficient, thereby reducing consumable costs for PCR to nearly
259		half when compared to standard volumes of 25-50 µl.
260	•	Issue 4: using gel electrophoresis for checking amplification success of each PCR
261		product.

262 This time-consuming step is only justified when Sanger sequencing is used or when 263 high-priority specimens are barcoded. It is not necessary when barcoding large numbers 264 of specimens with modern sequencing technologies, because failed amplicons do not 265 add to the sequencing cost. Furthermore, specimens that failed to yield barcodes during 266 the first sequencing run can be re-sequenced or re-amplified and then added to 267 subsequent sequencing runs (Srivathsan, Hartop et al. 2019). We thus only use gel 268 electrophoresis to check a small number of reactions per microplate (N=8-12, including 269 the negative control) in order to make sure that there was no plate-wide failure.

270

271 The fifth issue requires more elaboration and concerns how to efficiently tag amplicons. We 272 tag via a single PCR reaction (Meier, Wong et al. 2016) using primers including the tag at 273 the 5' end because it is simpler than the dual-PCR tagging strategy dominating the literature. 274 The latter has numerous disadvantages when applied to one gene: it doubles the cost by 275 requiring two rounds of PCR, is more labour intensive, increases the risk for PCR errors by 276 requiring more cycles, and requires clean-up of every PCR product after the first round of 277 amplification. In contrast, tagging via a single PCR is simple and costs the same as any 278 gene amplification. It is here described for a microplate with 96 templates, but the protocol 279 can be adapted to the use of strip tubes or half-plates. What is needed is a 96-well primer

plate where each well contains a differently tagged reverse primer. This "primer plate" can yield 96 unique combinations of primers once the 96 reverse primers are combined with the one forward primer (f-primer x 96 differently tagged r-primers = 96 unique combinations). This also means that if one purchases 105 differently tagged forward primers, one can individually tag 10,800 specimens (105 x 96= 10,800 amplicons). This is the number of amplicons that we consider appropriate for a MinION flow cell (R10.3; see below).

286

287 Assigning tag combinations is also straightforward. For each plate with 96 PCR reactions, 288 add the same f-primer to a tube with the PCR master mix (Taq DNA polymerase, buffer and 289 dNTPs) for the plate. Then dispense the "f-primed" master mix into the 96-wells. Afterwards, 290 use a multichannel pipette to add the DNA template and the tagged r-primers from the r-291 primer plate into the PCR plate. All 96 samples in the plate now have a unique combination 292 of tagged primers because they only share the same tagged forward primer. This makes the 293 tracking of tag combinations simple because each PCR plate has its own tagged f-primer, 294 while the r-primer is consistently tied to well position. Each plate has a negative control to 295 ensure that no widespread contamination has occurred. The tagging information for each 296 plate is recorded in the demultiplexing file that is later used to demultiplex the reads obtained 297 during sequencing.

298

299 Some users may worry that the purchase of many primers is expensive, but one must keep 300 in mind that the amount of primer used in a PCR reaction is constant. Therefore, single

301 PCR-tagging only means a greater upfront investment. Ordering all primers at once,

302 however, does mean that one must be much more careful about avoiding primer

303 degeneration and contamination as the stock will last longer. Primer stock should be stored

at -80°C and the number of freeze-thaw cycles should be kept low (<10). This means that

305 upon receipt of the primer stock, it should be immediately aliquoted into plates/tubes holding

306 only enough primer for rapid use. For fieldwork, one should only bring enough dissolved

307 primer for the necessary experiments, or rely on lyophilised reagents.

508	
309	The choice of tag length is determined by three factors. Longer tags reduce PCR success
310	rates (Srivathsan, Hartop et al. 2019) while they increase the proportion of reads that can be
311	assigned to a specific specimen (demultiplexing rate). Designing tags is not straightforward
312	because they must remain sufficiently distinct (>4bp from each other including
313	insertions/deletions) while avoiding homopolymers. We include a list of 13 bp tags that are
314	suitable in supplementary materials.
315	
316	Methods for step 3: Amplicon sequencing. The use of the PCR techniques described so far
317	should keep the cost for a tagged barcode amplicon to 0.05-0.10 USD as long as the user
318	buys cost-effective consumables. What comes next is the purification of the amplicons via
319	the removal of unused PCR reagents, the adjustment of DNA concentration, and
320	sequencing. Sequencing can be done with Sanger sequencing, Oxford Nanopore
321	Technologies (ONT) (e.g., MinION: Srivathsan, Hartop et al. 2019), Illumina (Wang,
322	Srivathsan et al. 2018), or PacBio (e.g., Sequel: Hebert, Braukmann et al. 2018). Users
323	select the sequencing option that best suit their needs based on five major criteria: (1)
324	Scaling; i.e., ability to accommodate projects of different sizes, (2) turnaround times, (3) cost,
325	(4) amplicon length and (5) sequencing error rate. Sanger sequencing has fast turnaround
326	times but high sequencing cost per amplicon (\$3-4 USD). This is the only method where cost
327	scales linearly with the number of amplicons that need sequencing, while the other
328	sequencing techniques are fundamentally different in that each run has two fixed costs that
329	stay the same regardless of whether only a few or the maximum number of amplicons for the
330	respective flow cells are sequenced. The fixed costs are library preparation (preparing
331	amplicons for sequencing) and flow cell.
332	

The MinION Flongle has the lowest fixed costs (library and flow cell: ca. \$120 USD for a routine run) and we show here that it has sufficient capacity for ca. 250 barcodes. The adapter for flongle can be purchased as part of a package that costs \$1460 USD, which also 336 includes 12 flow cells thus increasing the cost of the first 12 runs to ~\$170 USD. The 337 turnaround time is fast, so the MinION Flongle is arguably the best sequencing option for 338 small barcoding projects with > 50 barcodes. Full MinION flow cells also have fast 339 turnaround times, but the minimum run cost is ca. 1000 USD, so this option only becomes 340 more cost-effective than Flongle when >1800 amplicons are sequenced. As shown later, one 341 regular MinION flow cell can comfortably sequence 10,000 amplicons. This is a similar 342 volume to what has been described for PacBio (Sequel) (Hebert, Braukmann et al. 2018), 343 but the high instrument cost for PacBio means that sequencing usually has to be 344 outsourced, leading to longer wait times. By far the most cost-effective sequencing method 345 for barcodes is Illumina's NovaSeg sequencing. The fixed costs for library and lanes are high 346 (3000-4000 USD), but each flow cell yields 800 million reads which can comfortably 347 sequence 800,000 barcodes at a cost of < \$0.01 USD per barcode. This high capacity 348 means that the 6 million publicly available barcodes in BOLD Systems could have been 349 sequenced on just <8 NovaSeq flow cells for ~50,000 USD. However, Illumina sequencing 350 can only be used for mini-barcodes of up to 420 bp length (using 250bp PE sequencing 351 using SP flow cell). "Full-length" COI barcode (658 bp) can only be obtained by sequencing 352 two amplicons. Note that while Illumina barcodes are shorter than "full-length" barcodes, 353 there is no evidence that mini-barcodes have a negative impact on species delimitation or 354 identification as long as the mini-barcode is >250 bp in length (Yeo, Srivathsan et al. 2020). 355

356 Simplified techniques for sequencing tagged amplicons: Modern sequencing technologies 357 are used to sequence amplicon pools instead of individual amplicons. To obtain such a pool, 358 it is sufficient to combine only 1 µl per PCR product. The pool can be cleaned using several 359 PCR clean-up methods. We generally use SPRI bead-based clean-up, with Ampure 360 (Beckman Coulter) beads but Kapa beads (Roche) or the more cost-effective Sera-Mag 361 beads (GE Healthcare Life Sciences) in PEG (Rohland and Reich 2012) are also viable 362 options (Srivathsan, Hartop et al. 2019). We recommend the use of a 0.5X ratio for Ampure 363 beads for barcodes longer than 300 bp since it removes a larger proportion of primers and

364 primer dimers. However, this ratio is only suitable if yield is not a concern (e.g., pools 365 consisting of many and/or high concentration amplicons). Increasing the ratio to 0.7-1X will 366 improve yield but render the clean-up less effective. Amplicon pools containing large 367 numbers of amplicons usually require multiple rounds of clean-up, but only a small subset of 368 the entire pool needs to be purified because most library preparation kits require only small 369 amounts of DNA. Note that the success of the clean-up procedures should be verified with 370 gel electrophoresis, which should yield only one strong band of expected length. After the 371 clean-up, the pooled DNA concentration is measured in order to use an appropriate amount 372 of DNA for library preparation. Most laboratories use a Qubit, but less precise techniques are 373 probably also suitable.

374

375 Obtaining a cleaned amplicon pool according to the outlined protocol is not time consuming. 376 However, many studies retain "old Sanger sequencing habits". For example, they use gel 377 electrophoresis for each PCR reaction to test whether an amplicon has been obtained and 378 then clean and measure all amplicons one at a time for normalization (often with very 379 expensive techniques: Ampure beads: (Maestri, Cosetino et al. 2019); TapeStation, 380 BioAnalyzer, Qubit: (Seah, Lim et al. 2020)). This is presumably done to obtain a pool of 381 amplicons where each has equal representation. However, reads are cheap while individual 382 clean-ups and measurements for each PCR product are expensive. Furthermore, weak 383 products that failed to yield a barcode can be re-sequenced (Srivathsan, Hartop et al 2019). 384 Another strategy is normalization based on the band strength of a few PCR products per 385 plate as determined by gel electrophoresis. We used this strategy in the current study, but 386 have since determined that pooling without such normalization yields nearly identical 387 success rates based on the same number of reads (>9600 amplicons: 76.8% vs. 77.2%). 388 389 3. MinION barcoding with new flow cells (R10.3, Flongle) and high-accuracy

390 basecalling

391 Oxford Nanopore Technologies (ONT) instruments sequence DNA by passing single-392 stranded DNA through a nanopore. This creates current fluctuations which can be measured 393 and translated into a DNA sequence via basecalling (Wick 2019). The sequencing devices 394 are small and inexpensive, but the read accuracy is only moderate (85% - 95%) (Wick 2019, 395 Silvestre-Ryan and Holmes 2021). This means that data analysis requires specialized 396 bioinformatics pipelines. The nanopores used for sequencing are arranged on flow cells, with 397 new flow cell chemistries and basecalling softwares regularly released. Recently, three 398 significant changes occurred. Firstly, ONT released a cheap flow cell (Flongle) that only has 399 126 pores (126 channels) instead of the customary 2048 pores (512 channels) of a full 400 MinION flow cell. We were interested in Flongle because it looked promising for small 401 barcoding projects that needed quick turnaround times. Secondly, ONT released a new flow 402 cell chemistry for full flowcells (R10.3) where the nanopores have a dual instead of a single 403 reader-head. Dual reading has altered the read error profile by giving better resolution to 404 homopolymers and improving consensus accuracy (Chang, Ip et al. 2020, Vereecke, Bokma 405 et al. 2020). Lastly, ONT released high accuracy (HAC) basecalling. We thus obtained 406 amplicons using techniques described in Section 2 and processed them further as described 407 below.

408

409 Library preparation. Library preparation was based on 200 ng of DNA for the full MinION flow 410 cells and 100 ng for the Flongle and used ligation-based kits(see Table 1 for details). We 411 generally followed kit instructions, but excluded the FFPE DNA repair mix in the end-repair 412 reaction, as this is mostly needed for formalin-fixed, paraffin-embedded samples. The 413 reaction volumes for the R10.3 flow cell libraries consisted of 45 µl of DNA, 7 µl of Ultra II 414 End-prep reaction buffer (New England Biolabs), 3 µl of Ultra II End Prep enzyme mix (New 415 England Biolabs) and 5 µl of molecular grade water. For the Flongle, only half of the 416 reagents were used to obtain a total volume of 30 µl. We further modified the Ampure ratio 417 to 1x for all steps as DNA barcodes are short whereas the recommended ratio in the manual 418 is for longer DNA fragments. The libraries were loaded and sequenced with a MinION Mk

419 1B. Data capture involved a MinIT or a Macintosh computer that meets the IT specifications 420 recommended by ONT. The bases were called using Guppy (versions provided in Table 2), 421 under the high-accuracy model in MinIT taking advantage of its GPU. 422 423 Sequencing. Six amplicon pools were sequenced (Table 1). For two of the pools, Mixed 424 Diptera (N=511) and Afrotropical (N=4,275) Phoridae, we had comparison barcodes that 425 were obtained with Sanger and Illumina sequencing and the same amplicon pools were 426 previously sequenced with earlier versions of MinION flow cells (Srivathsan, Baloglu et al. 427 2018, Srivathsan, Hartop et al. 2019) (Table 1). These two pools were used to assess the 428 accuracy of barcodes generated using R10.3 flow cells. Two additional datasets tested the 429 capacity of R10.3 flowcells for mini- and full length barcodes for the same specimens 430 (Palaearctic Phoridae, 658 and 313 bp for ca. 9,930 specimens). The Mixed Diptera 431 Subsample and Chironomidae datasets test the performance of the Flongle. The Mixed 432 Diptera Subsample (N=257) is a subset of the Mixed Diptera (N=511) amplicon pool for 433 which we have Sanger barcodes for comparison. The Chironomidae dataset contains 434 sequences for 313 bp mini-barcodes for 191 specimens of Chironomidae that were newly 435

436

amplified for this study.

441 Bioinformatics

442	One of the most significant barriers to widespread barcoding with MinION is the high error
443	rates of ONT reads. In 2018, we developed a bioinformatics pipeline for error correction that
444	was too complex for the average user (Srivathsan, Baloglu et al. 2018, Srivathsan, Hartop et
445	al. 2019). After obtaining data with several R10.3 and new R9.4 flow cells, we initially applied
446	this pipeline (Srivathsan et al. 2019), but we noticed major improvements in terms of MinION
447	read quality and the total number of raw and demultiplexed reads produced by each flow
448	cell. This led to the development of a new user-friendly pipeline after considering alternative,
449	published pipelines which faced one or several of the following problems: they required high
450	read coverage, relied on external sequences, were complex, and/or needed several
451	command line steps, and included external dependencies that limit cross platform
452	compatibility (Menegon, Cantaloni et al. 2017, Maestri, Cosetino et al. 2019, Seah, Lim et al.
453	2020, Sahlin, Lim et al. 2021). We here present "ONTbarcoder", which has a graphical user
454	interface (GUI) and is suitable for all major operating systems (Linux, Mac OS, Windows10).
455	Both are requirements for the democratization of barcoding with MinION. In addition, we
456	prepared a simple video tutorial
457	(https://www.youtube.com/channel/UC1WowokomhQJRc71FmsUAcg).
458	
459	ONTbarcoder. ONTbarcoder (available at: https://github.com/asrivathsan/ONTbarcoder) has
460	three modules. (a) The first is a demultiplexing module which assigns reads to specimen-
461	specific bins. (b) The second is a barcode calling module which reconstructs the barcodes
462	based on the reads in each specimen bin. (c) The third is a barcode comparison module that
463	allows for comparing barcodes obtained via different software and software settings.
464	
465	a. Demultiplexing. The user provides three pieces of information and two files: (1) primer
466	sequence, (2) expected fragment length, and (3) demultiplexing information (=tag
467	combination for each specimen). The latter is summarized in a demultiplexing file (see
468	supplementary information for format). The only other required file is the FASTQ file

469 obtained from MinKNOW/Guppy after basecalling. Demultiplexing by ONTbarcoder starts by 470 analyzing the read length distribution in the FASTQ file. Only those reads that meet the read 471 length threshold are demultiplexed (default= 658 bp corresponding to metazoan COI 472 barcode). Technically, the threshold should be the amplicon length plus the length of both 473 tagged primers, but ONT reads have indel errors such that they are occasionally too short 474 and we therefore advise to specify the amplicon length as threshold. Reads that are twice 475 the expected fragment length are split into two parts. Splitting is based on the user given 476 fragment size, primer and tag lengths, and a window size to account for indel errors 477 (default=100 bp).

478

479 Once all reads suitable for demultiplexing have been identified, ONTbarcoder finds the 480 primers via sequence alignment of the primer sequence to the reads (using python library 481 edlib). Up to 10 deviations from the primer sequence are allowed because this step is only 482 needed for determining the primer location and orientation within the read. For 483 demultiplexing, the flanking region of the primer sequence is retrieved whereby the number 484 of retrieved bases is equal to the user-specified tag length. The flanking sequences are then 485 matched against the tags from the user-provided tag combinations (demultiplexing file). In 486 order to account for sequencing errors, not only exact matches are accepted, but also 487 matches to "tag variants" that differ by up to 2 bps from the original tag 488 (substitutions/insertions/deletions). Note that accepting tag variants does not lead to 489 demultiplexing error because all tags differ by >4 bp. All reads thus identified as belonging to 490 the same specimen are pooled into the same bin. To increase efficiency, demultiplexing is 491 parallelized and the search space for primers and tags are restricted to user-specified parts 492 of each read.

493

<u>b. Barcode calling</u>: Barcode calling uses the reads within each specimen-specific bin to
 reconstruct the barcode sequence. The reads are aligned to each other and a consensus
 sequence is called. Barcode calling is done in three phases: "Consensus by Length",

497 "Consensus by Similarity" and "Consensus by barcode comparison". The user can opt to498 only use some of these methods.

499

500 "Consensus by Length" is the main barcode calling mode. Alignment must be efficient in 501 order to obtain high-quality barcodes at reasonable speed for thousands of amplicons. 502 ONTbarcoder delivers speed by using an iterative approach that gradually increases the 503 number of reads ("coverage") that is used during alignment. However, reconstructing 504 barcodes based on few reads could lead to errors which are here weeded out by using four 505 Quality Control (QC) criteria. The first three QC criteria are applied immediately after the 506 consensus sequence has been called: (1) the barcode must be translatable, (2) it has to 507 match the user-specified barcode length, and (3) the barcode has to be free of ambiguous 508 bases ("N"). To increase the chance of finding a barcode that meets all three criteria, we 509 subsample the reads in each bin by read length (thus the name "Consensus by Length"); 510 i.e., initially only those reads closest to the expected length of the barcode are used. For 511 example, if the user specified coverage=25x for a 658 bp barcode, ONTbarcoder would only 512 use the 25 reads that have the closest match to 658 bp. The fourth QC measure is only 513 applied to barcodes that have already met the first three QC criteria. A multiple sequence 514 alignment (MSA) is built for the barcodes obtained from the amplicon pool, and any barcode 515 that causes the insertion of gaps in the MSA is rejected. Note that if the user suspects that 516 barcodes of different length are in the amplicon pool, the initial analysis should use the 517 dominant barcode length. The remaining barcodes can then be recovered by re-analyzing all 518 data or only the failed read bins ("remaining", see below) and bins that yielded barcodes that 519 had to be "fixed". These bins can be reanalyzed using a different pre-set barcode length.

520

"Consensus by Similarity". The barcodes that failed the QC during the "Consensus by
Length" stage are often close to the expected length and have few ambiguous bases, and/or
cause few gaps in the MSA. These "preliminary barcodes" can be improved through
"Consensus by Similarity". This method eliminates outlier reads from the read alignments.

525 Such reads often differ considerably from the signal of the consensus barcode and 526 ONTbarcoder identifies them by sorting all reads by similarity to the preliminary barcode. 527 Only the top 100 reads (this default can be changed) that differ by <10% from the 528 preliminary barcode are retained and used for calling the barcodes again using the same 529 techniques described previously (including the same QC criteria). This distance threshold 530 accounts for errors generated by MinION but excludes highly erroneous or contaminating 531 reads. This improvement step converts many preliminary barcodes found during "Consensus" 532 by Length" into barcodes that pass all four QC criteria by filling/removing indels or resolving 533 an ambiguous base.

534

535 "Consensus by barcode comparison". The remaining preliminary barcodes that still failed to 536 convert into QC-compliant barcodes tend to be based on read bins with low coverage, but 537 some can yield good barcodes after subjecting them to a further improvement step that fixes 538 the remaining errors. ONTbarcoder identifies these errors by finding the 20 most similar QC-539 compliant barcodes that have already been reconstructed for the other amplicons. The 21 540 sequences are aligned and ONTbarcoder finds the errors because they cause insertions and 541 deletions in the MSA. Insertions are deleted, gaps are filled with ambiguous bases ("N"), but 542 mismatches are retained. The number and kinds of "fixes" are recorded and added to the 543 FASTA header of the barcode.

544

545 Output. ONTbarcoder extensively documents the barcoding results so that users can check 546 the output and potentially modify the barcode calling parameters. For example, it produces a 547 summary table (Outputtable.csv) and FASTA files that contain the different classes of 548 barcodes. Each barcode header contains information on coverage used for barcode calling, 549 coverage of the specimen bin, length of the barcode, number of ambiguities and number of 550 indels fixed. Five sets of barcodes are provided, here discussed in the order of barcode 551 quality: (1) "QC_compliant": The barcodes in this set satisfy all four QC criteria without 552 correction and are the highest quality barcodes. (2) "Filtered barcodes": this file contains the 553 barcodes that are translatable, have <1% ambiguities and have up to 5 indels fixed during 554 the last step of the bioinformatics pipeline. These filtering thresholds were calibrated based 555 on two datasets for which we have Sanger/Illumina barcodes and the resulting barcodes are 556 found to be highly accurate. Note that the file with filtered barcodes also includes the 557 QC_compliant barcodes and that all results discussed in this manuscript are based on 558 filtered barcodes given that they are of much higher quality than the average barcode in 559 BOLDSystems (assessment in Srivathsan, Baloğlu et al 2018). 560 561 The remaining files include barcodes of lesser and/or suspect quality. (3) 562 "Fixed barcodes XtoY": these files contain barcodes that had indel errors fixed and are 563 grouped by the number of errors fixed. Only the barcodes with 1-5 errors overlap with 564 Filtered barcodes file, if they have <1% ambiguities. (4) "Allbarcodes": this file contains all 565 barcodes in sets (1)-(3). (5) "Remaining": these are barcodes that fail to either translate or 566 are not of predicted length. Note that all barcodes should be checked via BLAST against 567 comprehensive databases in order to detect contamination. There are several online tools 568 available for this and we recommend the use of GBIF sequence ID tool 569 (https://www.gbif.org/tools/sequence-id) which gives straightforward output including a 570 taxonomic summary. 571 572 The output folder also includes the FASTA files that were used for alignment and barcode 573 calling. The raw read bins are in the "demultiplexed" folder, while the resampled bins (by

574 length, coverage, and similarity) are in their respective subfolders named after the search

step. Note that the raw reads are encoded to contain information on the orientation of the

- sequence and thus cannot be directly used in other software without modifications (see
- 577 ONTbarcoder manual on Github). Lastly, for each barcode FASTA file (1-5), there are
- 578 folders with the files that were used to call the barcodes. This means that the user can, for
- 579 example, reanalyze those bins that yielded barcodes with high numbers of ambiguous

580 bases. Lastly a "runsummary.xlsx" document allows the user to explore the details of the

581 barcodes obtained at every step of the pipeline.

582 Algorithms. ONTbarcoder uses the following published algorithms. All alignments utilize 583 MAFFTv7 (Katoh and Standley 2013). The MSAs that use MinION reads to form a 584 consensus barcode are constructed in an approach similar to lamassemble (Frith, 585 Mitsuhashi et al. 2020), using parameters optimized for nanopore data by "last-train" 586 (Hamada, Ono et al. 2017) which accounts for strand specific error biases. The MAFFT 587 parameters can be modified in the "parfile" supplied with the software which will help with 588 adjusting the values given the rapidly changing nanopore technology. All remaining MSAs in 589 the pipeline (e.g., of preliminary barcodes) use MAFFT's default settings. All read and 590 sequence similarities are determined with the *edlib* python library under the Needle-Wunsch 591 ("NW") setting, while primer search is using the infix options ("HW"). All consensus 592 sequences are called from within the software. This is initially done based on a minimum 593 frequency of 0.3 for each position. This threshold was empirically determined based on 594 datasets where MinION barcodes can be compared to Sanger/Illumina barcodes. The 595 threshold is applied as follows. All sites where >70% of the reads have a gap are deleted. 596 For the remaining sites, ONTbarcoder accepts those consensus bases that are found in at 597 least >30% of the reads. If no base/multiple bases reach this threshold, an "N" is inserted. 598 To avoid reliance on a single threshold, ONTbarcoder allows the user to change the 599 consensus calling threshold from 0.2 to 0.5 for all barcodes that fail the QC criteria at 0.3 600 frequency. However, barcodes called at different frequencies are only accepted if they pass 601 the first three QC criteria and are identical. If no such barcode is found, the 0.3 frequency 602 consensus barcode is used for further processing.

603

604 <u>c. Barcode comparison</u>. Many users may want to call their barcodes under different settings 605 and then compare barcode sets. The ONTbarcoder GUI simplifies such comparisons. A set 606 of barcodes is dragged into the window and the user can select a barcode set as the 607 reference. The barcode comparisons are conducted using *edlib* library. The barcodes in the 608 sets are compared and classified into three categories: "identical" where sequences are a 609 perfect match and lack ambiguities, "compatible" where the sequences only differ by 610 ambiguities, and "incorrect" where the sequences differ by at least one base pair. Several 611 output files are provided. A summary sheet, a FASTA file each for "identical", "compatible", 612 and the sequences only found in one dataset. Lastly, there is a folder with FASTA files 613 containing the different barcodes for each incompatible set of sequences. This module can 614 be used for either comparing set(s) of barcodes to reference sequences, or for comparing 615 barcode sets against each other. It furthermore allows for pairwise comparisons and 616 comparisons of multiple sets in an all-vs-all manner. This module was used here to get the 617 final accuracy values presented in Table 3. 618 619 4. Performance of flow cells (R10.3, Flongle) and high-accuracy basecalling The pools used to test the new ONT products contained amplicons for 191 - 9,932 620 621 specimens and were run for 15-49 hours (Table 2). The fast5 files were basecalled using 622 Guppy in MinIT under the high accuracy (HAC) model. Basecalling large datasets under 623 HAC is currently still very slow and took 12 days in MinIT for the Palaearctic Phoridae (658 624 bp) dataset (Table 2) but the reads yielded high demultiplexing rates for three of the four

- R10.3 MinION datasets (= 30-49%). The exception was the *Palaearctic Phoridae (313 bp)*
- dataset (15.5%). Flongle datasets showed overall also lower demultiplexing rates (17-21%).

627

628 **Table 2**. Datasets generated in this study and the results of barcoding using ONTbarcoder at

- 200X coverage (Consensus by Length) and 100X coverage (Consensus by Similarity).

⁶³¹

632 We used ONTbarcoder to analyze the MinION data for all six datasets by analyzing all

633 specimen-specific read bins at different coverages (5-200x in steps of 5x). This means that

the barcodes for a bin with 27 reads were called five times at 5x, 10x, 15x, 20x, and 25x

635 coverages while bins with >200x were analyzed 40 times at 5x increments. Instead of using

636 conventional rarefaction via random subsampling reads, we used the first reads provided by

the flow cell because this accurately reflects how the data accumulated during the
sequencing run and how many barcodes would have been obtained if the run had been
stopped early. This rarefaction approach also allowed for mapping the barcode success
rates against either coverage or time.

641

642 In order to obtain a "best" estimate for how many barcodes can be obtained, we also carried 643 out one analysis at 200x coverage with the maximum number of "Comparison by Similarity" 644 reads set to 100. This means that ONTbarcoder selected up to 200 reads from the 645 specimen-specific read bin that had the closest match to the length of the target barcode 646 (i.e., 313 or 658 bp), then produced an MSA and consensus barcode using MAFFT. If the 647 resulting consensus barcode did not satisfy all four QC criteria, ONTbarcoder would select 648 up to 100 reads that had at least a 90% match to the preliminary barcode. These reads 649 would then be used to call another barcode with MAFFT. Only if this also failed to produce a 650 QC-compliant barcode, ONTbarcoder would "fix" the preliminary barcode using its 20 closest 651 matches in the dataset. All analyses produced a "filtered" set of barcodes (barcodes with 652 <1% Ns and up to 5 fixes) that were used for assessing the accuracy and quality via 653 comparison with Sanger and Illumina barcodes for Mixed Diptera (MinION R10.3), 654 Afrotropical Phoridae (MinION R10.3), and Mixed Diptera Subsample (Flongle R9.4). For the 655 comparisons of the barcode sets obtained at the various coverages, we used MAFFT and 656 the assess_corrected_barcode.py script in miniBarcoder (Srivathsan et al., 2019). 657

We investigated barcode accuracy (Figure 1) by directly aligning the MinION barcodes with the corresponding Sanger and Illumina barcodes. We find that MinION barcodes are virtually identical to Sanger and Illumina barcodes (>99.99% identity, Table 3). We then established that the number of ambiguous bases ("N") is also very low for barcodes obtained with R10.3 (<0.01%). Indeed, more than 90% of all barcodes are entirely free of ambiguous bases. In comparison, Flongle barcodes have a slightly higher proportion of ambiguous bases (<0.06%). They are concentrated in ~20% of all sequences so that 80% of all barcodes

again lack Ns. This means that MinION barcodes more than just match the Consortium for
the Barcode of Life (CBOL) criteria for "barcode" designation with regard to length, accuracy,
and ambiguity.

668

669 Rarefaction at different read coverage levels reveals that 80-90% of high-quality barcodes 670 are obtained within a few hours of sequencing. In addition, the number of barcodes 671 generated by MinION exceeded or was comparable to what could be obtained with Sanger 672 or Illumina sequencing (Figure 1). We then determined the coverage needed for obtaining 673 reliable barcodes. For this purpose, we plotted the number of barcodes obtained against 674 coverage (Figure 2). This revealed that the vast majority of specimen bins yield high-quality 675 barcodes at coverages between 25x and 50x when R10.3 reads are used. Increasing 676 coverage beyond 50x leads to only modest improvements of quality and few additional 677 specimen amplicons yield new barcodes. The coverage needed for obtaining Flongle barcodes is somewhat higher, but the main difference between the R9.4 technology of the 678 679 Flongle flow cell and R10.3 is that more barcodes retain ambiguous bases even at high 680 coverage for data from R9.4 flow cells. The differences in read quality between R9.4 and 681 R10.3 become even more obvious when the read bins for the "Mixed Diptera Subsample" 682 are analyzed based an identical numbers of R10.3 and R9.4 reads. The barcodes based on 683 Flongle and R10.3 data are compatible, but the R10.3 barcodes are ambiguity-free while 684 some of the corresponding Flongle barcodes retain 1-2 ambiguous bases. 685

Overall, these results imply that 100x raw read coverage is sufficient for obtaining barcodes with either R10.3 or R9.4 flow cells. Given that most MinION flow cells yield >10 million reads of an appropriate length, this means that one could, in principle, obtain 100,000 barcodes in one flow cell. However, this would require that all amplicons are represented by similar numbers of copies and that all reads could be correctly demultiplexed. In reality, only 30-50% of the reads can be demultiplexed and the number of reads per amplicon fluctuates widely (Figure 3). Very-low coverage bins tend to yield no barcodes or barcodes of lower

quality (errors or Ns). These low-coverage barcodes can be improved by collecting more
data, but this comes at a high cost and increased risk of a small number of contaminant
reads yielding barcodes. For example, we observed that some "negative" PCR controls
yielded low-quality barcodes for 4 of 106 negatives in the Palaearctic Phoridae (313 bp) and
1 of 105 negatives in the Palaearctic Phoridae (658 bp) datasets.

699 To facilitate the planning of barcode projects, we illustrate the trade-offs between barcode 700 yield, time, and amount of raw data needed for six amplicon pools (Figure 4: 191-9,932 701 specimens). These standard curves can be used to roughly estimate the amount of raw 702 reads needed to achieve a specific goal for a barcoding project of a specific size (e.g., 703 obtaining 80% of all barcodes for a project with 1000 amplicons). For each dataset, we 704 illustrate how many reads were needed to recover a certain proportion of barcodes. The 705 number of recoverable barcodes was set to the number of all error-free, filtered barcodes 706 obtained in an analysis of all data. We would argue that this is a realistic estimate of 707 recoverable barcodes given the saturation plots in Figure 1 that suggest that most barcodes 708 with significant amounts of data have been called at 200x coverage. Note, however, that 709 Figure 4 can only provide very rough guidance on how many reads are needed because, for 710 example, the demultiplexing rates differ between flow cells and different amplicon pools have 711 very different read abundance distributions (see Figure 3).

712

713 **Table 3.** Quality assessment of barcodes generated by ONTbarcoder at 200X read

coverage (Consensus by Length) and 100X coverage (Consensus by Similarity). The

accuracy of MinION barcodes is compared with the barcodes obtained for the same

specimens using Illumina/Sanger sequencing. Errors are defined as sum of substitution or

717 indel errors. All denominators for calculating percentages are the total number of nucleotides

718 assessed.

719

Dataset	No. of comparison barcodes	No. of barcodes with errors/No. of errors/% identity	# of Ns/%Ns
R10.3: Mixed Diptera: Sanger barcodes available	476	2/10/99.997%	19 (0.006%)
R10.3: Afrotropical Phoridae: Illumina barcodes available*	3316	23/48/99.995%	284 (0.011%)
Flongle-Mixed Diptera Subsample: Sanger barcodes available	231	5/8/99.994%	91 (0.058%)

720

*5 barcodes with very high distances from reference were excluded for R10.3: Afrotropical Phoridae dataset as

they likely represent lab contamination (see Srivathsan, Hartop et al. (2019).

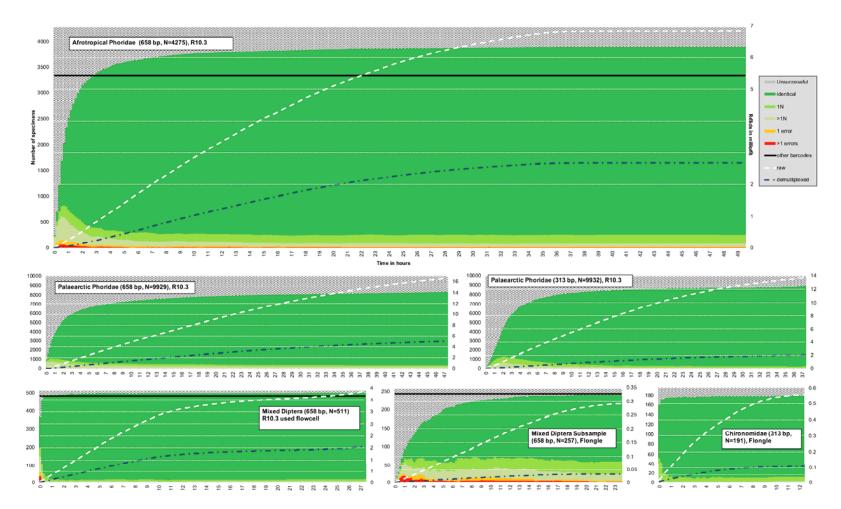

Figure 1. Rapid recovery of accurate MinION barcodes over time (in hours, x-axis) (filtered barcodes: dark green = barcodes passing all 4 QC criteria, light green = one ambiguous base; lighter green = more than 1N, no barcode = white with pattern, 1 mismatch = orange, >1 mismatch = red). The solid black line represents the number of barcodes available for comparison. White dotted line represents the amount of raw reads collected over time, blue represents number of demultiplexed reads over time (plotted against Z-axis)

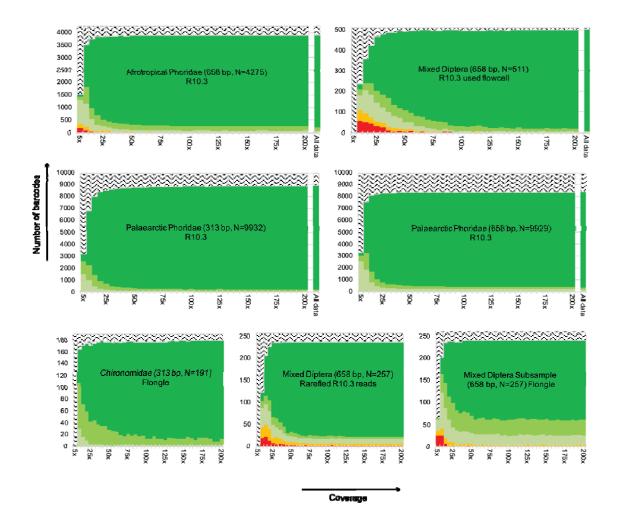

Figure 2. Relationship between barcode quality and coverage. Subsetting the data to 5-200X coverage shows that there are very minor gains to barcode quality after 25-50X coverage. (filtered barcodes: dark green = barcodes passing all 4 QC criteria, light green = one ambiguous base; lighter green = more than 1N, no barcode = white with pattern, 1 mismatch = orange, >1 mismatch = red).

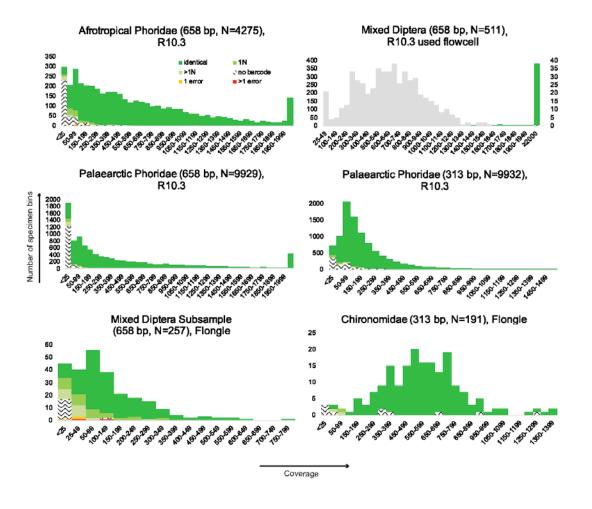

Figure 3. Read bin size distribution for six amplicon pools (color-coding as in Figs 1-2). Due to the very generous coverage for the "Mixed Diptera" dataset, we also use grey to show the bin size distribution after dividing the bin read totals by 5.

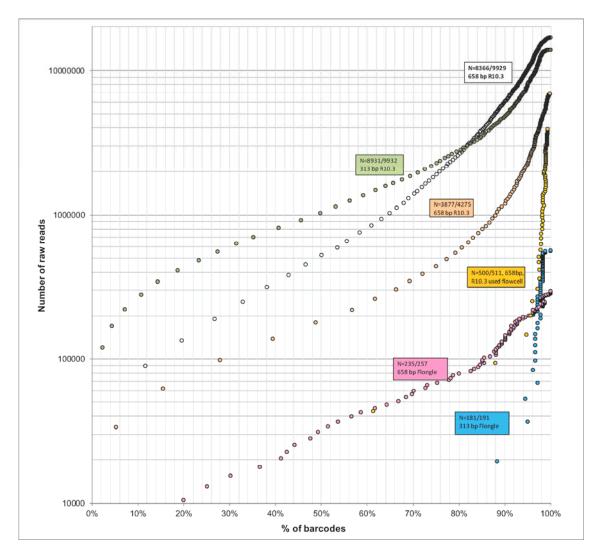

Figure 4. Relationship between barcoding success and number of raw reads for six amplicon pools (191-9932 specimens; barcoding success rates 84-97%). Percentage of barcodes recovered is relative to the final estimate based on all data.

722 Discussion

723 Democratization of Barcoding

724 Biodiversity research needs new scalable techniques for large-scale species discovery and 725 monitoring. This task is particularly urgent and challenging for invertebrates that collectively 726 make up most of the terrestrial animal biomass. We argued earlier that this is likely to be a 727 task that requires the processing of at least 500 million specimens from all over the world 728 with many tropical countries with limited research funding requiring much of the biodiversity 729 discovery work. Pre-sorting these specimens into putative species-level units with DNA 730 sequences is a promising solution as long as obtaining and analyzing the data are 731 sufficiently straightforward and cost-effective. We believe that the techniques described in 732 this manuscript will help with achieving these goals. Generating DNA barcodes involves 733 three steps. The first is obtaining a DNA template, and we have herein outlined some 734 simplified procedures that render this process essentially free-of-cost, although automation 735 and Al-based solutions will be useful for processing very large numbers of specimens in 736 countries with high manpower cost. The third step is the sequencing of the amplicon. Fortunately, there are now several cost-effective solutions based on 2nd and 3rd generation 737 738 sequencing technologies so that barcodes can be sequenced for as little as a penny (USD). 739

740 We here argue that sequencing with MinION is particularly attractive although the cost is 741 higher (0.10 USD) than with Illumina sequencing. There are several reasons. MinION library 742 preparation can be learned within hours and an automated library preparation instrument is 743 in development that will eventually work for ligation-based libraries. Furthermore, MinION 744 flow cells can accommodate projects of varying scales. Flongle can be used for amplicon 745 pools with a few hundred products, while an R10.3 flow cell can accommodate projects with 746 up to 10,000 specimens. The collection of data on MinION flow cells can be stopped 747 whenever enough have been acquired. Flow cells can then be washed and re-used again 748 although the remaining capacity declines over time because some nanopores will become 749 unavailable. We have re-used flow cells up to four times. Traditionally, the main obstacles to 750 using MinION have been poor read quality and high cost. Both issues are fading into the 751 past. The quality of MinION reads has improved to such a degree that the laptop-version of 752 our new software "ONTbarcoder" can generate thousands of very high quality barcodes 753 within hours. There is no longer a need to polish reads or rely on external data or algorithms. 754 The greater ease with which MinION barcodes can be obtained is due to several factors. 755 Firstly, much larger numbers of reads can now be obtained with one MinION flow cell. 756 Secondly, R10.3 reads have a different error profile which allows for reconstructing higher-757 quality barcodes. Thirdly, high accuracy basecalling has improved raw read quality and thus 758 demultiplexing rates. Lastly, we can now use parameter settings for MAFFT that are 759 designed for MinION reads. These changes mean that even low-coverage bins yield very 760 accurate barcodes; i.e., both barcode quality and quantity are greatly improved.

761

762 Rapid progress in barcode quality and quantity

763 We previously tested MinION for barcoding (2018, 2019) and here re-sequenced some of 764 the same amplicon pools. This allowed for a precise assessment of the improvements. In 765 2018, sequencing the 511 amplicons of the *Mixed Diptera* sample required one flow cell and 766 we obtained 488 barcodes of which only one lacked ambiguous bases. In 2021, we used the remaining ~500 pores of a used R10.3 flow cell (1st use was for 49 hours). After washing, we 767 768 obtained 502 barcodes and >98% (496) of them were free of ambiguous bases. The results 769 obtained for the 2019 amplicon pools were also better. In 2019, one flow cell (R9.4) allowed 770 us to obtain 3,223 barcodes from a pool of amplicons obtained from 4,275 specimens of 771 Afrotropical Phoridae. Resequencing weak amplicons increased the total number of 772 barcodes by approximately 500 to 3,762 (Srivathsan, Hartop et al. 2019). Now, one R10.3 773 flow cell yielded 3,905 barcodes (+143) for the same amplicon pool, while retaining an 774 accuracy of >99.99% and reducing the ambiguities from 0.45% to 0.01%. If progress 775 continues at this pace, we predict that MinION will be the default barcoding tool for most 776 users. This, too, is because all barcoding steps can now be carried out in one laboratory with 777 a modest set of equipment (see Table 4). With MinION being readily available, there is no

- 778 longer the need to outsource sequencing and/or to wait until enough barcode amplicons
- have been prepared for an Illumina or PacBio flow cell (Ho, Puniamoorthy et al. 2020). This
- 780 democratizes biodiversity discovery and allows many biologists, government agencies,
- students, and citizen scientists from around the globe to get involved in these initiatives.
- 782 Biodiversity discovery with cost-effective barcodes will also facilitate biodiversity discovery in
- 783 countries with high biodiversity but limited science funding.
- 784
- 785

Table 4. Equipment required for MinION barcoding

Required					
1	MinION sequencer (preferably Mk1C for basecalling)				
2	Thermocycler(s)				
3	Gel Electrophoresis setup				
4	Magnetic Separation Rack				
5	Qubit for DNA quantification				
6	<u>Standard equipment</u> : Vortex, Mini-centrifuge, pipettes, freezer, fridge				
7	Standard laptop or PC				
Optional but highly desirable					
1	Multichannel pipette(s)				
2	Hula Mixer				

786

787	This raises the question of how much it costs to sequence a barcode with MinION. There is
788	no straightforward answer because the cost depends on user targets. For example, a user
789	who wants to sequence a pool of 5000 barcodes may want a 80% success rate in order to
790	identify the dominant species in a sample. Based on Figure 4, only ca. 1.5 million raw
791	MinION reads would be needed. On average, MinION flow cells yield >10 million reads and
792	cost USD 475-900 depending on how many cells are purchased at the same time. Including

793 a library cost of ca. USD 100, the overall sequencing cost of a project that requires 1.5 794 million reads is USD 180-235. This experiment would be expected to yield 4000 barcodes for 795 the 5000 amplicons (4-6 cents/barcode). Given the low cost of 1 million MinION reads (\$50-796 90), we predict that most users will opt for sequencing at a greater depth since this will likely 797 yield several hundred additional barcodes. However, this will then increase the sequencing 798 cost per barcode, because the first 1.5 million reads already recovered barcodes for all 799 strong amplicons. Additional reads will predominantly strengthen read coverage for these 800 amplicons and relatively few reads will be added to the read bins that were too weak to yield 801 barcodes at low coverage; i.e., there are diminishing returns for additional sequencing. 802

803 Overall, we thus predict that most users will, at most, try to multiplex 10,000 amplicons in the 804 same MinION flow cell so that the sequencing cost per specimen would be 0.06-0.10 USD 805 depending on the bulk purchase of flow cells. However, we also predict that large-scale 806 biodiversity projects will switch to sequencing with PromethION, a larger sequencing unit 807 that can accommodate up to 48 flow cells. This will lower the sequencing cost by more than 808 60%, as PromethION flow cells have 6 times the number of pores for twice the cost (capacity 809 per flow cell should be 60,000 barcodes). At the other end of the scale are those users who 810 occasionally need a few hundred barcodes. They can use Flongle flow cells, which are 811 comparatively expensive (0.50 USD) because each flow cell costs \$70 and requires a library 812 that is prepared with half the normal reagents (ca. \$50). A change of the flow cell chemistry 813 from that of R9.4 to R10.3 would, however, help with improving the quality of the barcodes 814 obtained from Flongle. Lastly the initial setup cost for MinION/Flongle, can be as low as 815 1000 USD, but we recommend purchase of Mk1C unit (currently 4900 USD) for easy access 816 to a GPU that is required for high accuracy basecalling. Note also, that obtaining flow cells at 817 low cost often requires collaboration between several labs because it allows for buying flow 818 cells in bulk.

819

820 ONTbarcoder for large-scale species discovery with MinION

821 There are a number of studies that have used MinION for barcoding fungi, animals, and 822 plants (Menegon, Cantaloni et al. 2017, Pomerantz, Peñafiel et al. 2018, Wurzbacher, 823 Larsson et al. 2018, Krehenwinkel, Pomerantz et al. 2019, Maestri, Cosetino et al. 2019, 824 Chang, Ip et al. 2020, Chang, Ip et al. 2020, Knot, Zouganelis et al. 2020, Seah, Lim et al. 825 2020, Sahlin, Lim et al. 2021). There is one fundamental difference between these studies 826 and the vision presented here. These studies tended to show that MinION sequencing can 827 be done in the field. Thus only a very small number of specimens were analysed (<150 with 828 the exception of >500 in Chang, Ip et al 2020). The field use is an attractive feature for time-829 sensitive samples that could degrade before reaching a lab. However, for the time being it is 830 unlikely to help substantially with tackling the challenges related to large-scale biodiversity 831 discovery and monitoring because obtaining few MinION barcodes per flow cell is too 832 expensive for most researchers in biodiverse countries. Additionally, the bioinformatic 833 pipelines that were developed for these small-scale projects were not suitable for large-834 scale, decentralized barcoding in a large variety of facilities. For example, some of the 835 studies used ONT's commercial barcoding kit that only allows for multiplexing up to 96 836 samples in one flow cell (Maestri, Cosetino et al. 2019, Seah, Lim et al. 2020); i.e., each 837 amplicon had very high read coverage which influenced the corresponding bioinformatics 838 pipelines (e.g. ONTrack's recommendation is 1000x: Maestri, Cosentino et al. 2019). The 839 generation of such high coverage datasets also meant that the pipelines were only tested for 840 such a small number of samples (<60: Menegon, Cantaloni et al. 2017, Maestri, Cosetino et 841 al. 2019, Seah, Lim et al. 2020, Sahlin, Lim et al. 2021) that these tests were unlikely to 842 represent the complexities of large, multiplexed amplicon pools (e.g., nucleotide diversity, 843 uneven coverage).

844

ONTbarcoder evolved from miniBarcoder, whose barcodes have been assessed for
accuracy in four different studies covering >8000 barcodes (Chang, lp et al. 2020, Chang, lp
et al. 2020, Srivathsan, Baloglu et al. 2018, Srivathsan, Hartop et al. 2019). The new

software introduced here addresses two drawbacks of its precursor, miniBarcoder. Firstly,

849 we dropped the translation-based error correction that tended to increase the number of Ns. 850 This step used to be essential because indel errors were prevalent in consensus barcodes 851 obtained with older flow cell models. Secondly, ONTbarcoder can be installed by unzipping a 852 file and is easy to maintain on different operating systems. Until now, external dependencies 853 were a major drawback of all MinION bioinformatics pipelines. For example, the one 854 described by Sahlin et al. (2021) involved minibar/qcat and nanofilt, while NGSpeciesID 855 relies on isONclust SPOA, Parasail, and optionally, Medaka (Daily 2016, Krehenwinkel, 856 Pomerantz et al. 2019, Sahlin and Medvedev 2020). These dependencies and complexities 857 meant that Watsa et al. (2020) recommended bioinformatics training before MinION 858 barcoding could be used in schools (e.g., training in UNIX command-line) and additionally 859 required the installation of several software tools onto the teaching computers. Neither is 860 needed for ONTbarcoder, which runs on a regular laptop and has been extensively tested 861 (>4000 direct comparisons to Sanger and Illumina barcodes). In addition, ONTbarcoder is 862 designed in a way that thousands of barcodes can be obtained rapidly without impairing 863 accuracy; i.e., one can run a very fast analysis by using low read coverage. However, at very 864 low coverages, fewer barcodes would be recovered because many would not pass the 4 QC 865 criteria. Speed is also achieved through the parallelization of most steps on UNIX systems 866 (Mac and Linux; parallelization is restricted to demultiplexing in Windows).

867

868 ONTbarcoder also allows for updating the parameter file for alignment. This is advisable 869 because MinION continues to evolve quickly. We expect flow cell capacity to increase further 870 and basecalling to improve (see Xu, Mai et al. 2020). For example, a new basecaller 871 ("bonito") developed by ONT has shown promise by improving raw read accuracy 872 (https://nanoporetech.com/about-us/news/new-research-algorithms-yield-accuracy-gains-873 nanopore-sequencing). This basecaller is currently suitable for research teams equipped 874 with GPU infrastructure and for advanced users familiar with Linux command lines. 875 However, our preliminary tests of bonito for barcoding (Flongle: Mixed Diptera Subsample, 876 Chironomidae; R10.3: Palaearctic Phoridae, 313 bp; bonito version=0.3.6) does not yet

significantly affect barcode quality or quantity (unpublished data). However, this may change
in the immediate future and readers are advised to watch out for developments. Fortunately,
these changes will only further improve MinION barcodes that are already highly accurate
and cost-effective.

881

882 Biodiversity monitoring

883 Some readers are likely to argue that large-scale biodiversity discovery and monitoring can 884 be more efficiently carried out via metabarcoding of whole samples consisting of hundreds or 885 thousands of specimens. This would question the need for large-scale, decentralized 886 barcoding of individual specimens. However, large-scale barcoding and metabarcoding will 887 more likely complement each other. For example, large-scale barcoding of individual 888 specimens remains essential for discovering and describing species as it preserves 889 individual voucher specimens associated with the barcode which can be used for further 890 research. Taxonomic research can be guided by examination of putative species units 891 (molecular Operational Taxonomic Units or mOTUs) using species delimitation algorithms 892 (either distance based clustering of sequences: Meier, Shiyang et al. 2006; Puillandre, 893 Brouillet et al. 2020) or tree based methods (Pons, Barraclough et al. 2006; Zhang, Kapli et 894 al. 2013). In this process, it is important to remember that COI lumps recently diverged 895 species and divides species with deep allopatric splits (Hickerson, Meyer et al. 2006), 896 making the ability to relate barcodes to individual specimens critical for barcode cluster 897 validation. High quality barcode databases are important for the analysis of metabarcoding 898 data because they facilitate the identification of numts, heteroplasmy, contaminants and 899 errors. Large-scale barcoding will also be needed in order to benefit from another new 900 technique that may become critical for biodiversity discovery and monitoring; i.e. Al-assisted 901 analysis of images (Valan, Makonyi et al. 2019). Large-scale barcoding generates identified 902 specimens that can be imaged and utilized for training neural networks. With increasing 903 advancements in imaging hardware, computational processing power and machine learning 904 systems, Al-assisted biodiversity monitoring could be the method of choice in the future

905 because it could quickly determine and count many common species and only specimens

906 from new/rare species would still require barcoding.

907

908 Conclusions

909 Many biologists would like to have ready access to barcodes without having to run large and

910 complex laboratories or send specimens halfway around the world. Many have been

911 impressed by MinION's low cost, portability, and ability to deliver real-time sequencing, but

they were worried about high cost and complicated bioinformatics pipelines. We here

913 demonstrate that these concerns are no longer justified. MinION barcodes obtained by

914 R10.3 flow cells are virtually identical to barcodes obtained with Sanger and Illumina

sequencing. Barcoding with MinION is now also cost-effective and the new "ONTbarcoder"

software makes it straightforward for researchers with little bioinformatics background to

analyze the data on a standard laptop. This will make biodiversity discovery scalable and

918 accessible to all.

919

920 Acknowledgements

921 We would like to thank John T. Longino and Michael Branstetter for providing valuable 922 comments on the manuscript. For the Palaearctic phorid samples, we would like to thank 923 Dave Karlsson, the Swedish Insect Inventory Project, and the crew at Station Linné that 924 sorted out the phorids. We would also like to thank Wan Ting Lee for help with molecular 925 work, and the numerous staff, students and interns who have contributed to the 926 establishment of the pipeline in the NUS laboratory. We would also like to acknowledge 927 Suphavilai Chayaporn and Niranjan Nagarajan from Genome Institute of Singapore for their 928 help with basecalling using bonito. This work was supported by a Ministry of Education grant 929 on biodiversity discovery (R-154-000-A22-112).
