Summary

Terminating the SARS-CoV-2 pandemic relies upon pan-global vaccination. Current vaccines elicit neutralizing antibody responses to the virus spike derived from early isolates. However, new strains have emerged with multiple mutations: P.1 from Brazil, B.1.351 from South Africa and B.1.1.7 from the UK (12, 10 and 9 changes in the spike respectively). All have mutations in the ACE2 binding site with P.1 and B.1.351 having a virtually identical triplet: E484K, K417N/T and N501Y, which we show confer similar increased affinity for ACE2. We show that, surprisingly, P.1 is significantly less resistant to naturally acquired or vaccine induced antibody responses than B.1.351 suggesting that changes outside the RBD impact neutralisation. Monoclonal antibody 222 neutralises all three variants despite interacting with two of the ACE2 binding site mutations, we explain this through structural analysis and use the 222 light chain to largely restore neutralization potency to a major class of public antibodies.

Introduction

For more than a year SARS-CoV-2 has caused enormous global dislocation, leading to more than 2.5 million deaths (https://www.worldometers.info/coronavirus Accessed: 2021-03-01) and leaving no country untouched. Successive waves of infection have led to the imposition of draconian lock downs in many countries resulting in severe economic and societal disruption (Donthu and Gustafsson, 2020).

Enormous investment has been made in vaccine development with hundreds of vaccine candidates in different stages of development using an array of different platforms from RNA,

2

viral vectors, recombinant protein and inactivated (Krammer, 2020). Five vaccines have now been through large scale phase III trials and have demonstrated safety and efficacy (Polack et al., 2020;Voysey et al., 2020;Baden et al., 2020). Four of these, BNT162b2 (Pfizer-BioNTech; mRNA), mRNA-1273 (Moderna; mRNA), ChAdOx1 nCoV-19 (AZD1222) (Oxford-AstraZeneca; chimpanzee adenoviral vectored) and Ad26.COV2-S (Janssen; adenovirus serotype 26 vectored) have received emergency use authorization (EUA) in a variety of countries and are being rolled out at massive scale and NVX-CoV2373 (Novavax; recombinant protein) has also shown impressive efficacy and is likely to achieve EUA in the near future (https://www.medscape.com/viewarticle/944933 Accessed: 2021-03-01). All of these vaccines have been designed to raise antibodies (and T-cells) to spike protein (S) and because of the speed of development they all include S sequences derived from the first reported sequence from Wuhan in January 2020 (Lu et al., 2020).

SARS-CoV-2 like all RNA viruses has an error prone RNA polymerase, and despite some error correction, progressive accrual of mutational changes is inevitable. The massive scale of the pandemic which is largely uncontrolled leads to huge levels of viral replication, increasing the chances that adaptive mutations will occur. There are many possible ways whereby a mutation in SARS-CoV-2 may give the virus a selective advantage, however concentrating on mutation in S, there are two clear possibilities: increased efficiency of transmission and escape from neutralizing antibodies (Volz et al., 2021).

The S protein is a large Type-1 transmembrane glycoprotein which assembles into homo-trimers (Walls et al., 2020), which form most of the outer surface of coronaviruses. S is divided into two portions S1 and S2 which are cleaved by proteolysis. S1 is responsible for target cell engagement, whilst S2 completes membrane fusion allowing the viral RNA access to the host

104 cell cytoplasm where viral replication can begin. S1 contains an N terminal domain (NTD) and

105 receptor binding domain (RBD).

106

107 The RBD interacts with the cellular receptor angiotensin converting enzyme-2 (ACE2) which

108 is expressed on diverse cell types, including cells in the upper and lower respiratory tracts,

109 allowing SARS-CoV-2 to cause respiratory infection. The ACE2 interaction surface is a small

110 25 amino acid patch at the apex of spike, presented to ACE2 when the RBD swings upwards

111 (Hoffmann et al., 2020;Shang et al., 2020) and it is mutations in this region that are causing the

112 most concern. Three multiply mutated viral strains appeared independently at the end of 2020

113 in different regions where they rapidly expanded to become the dominant strains

114 (https://www.cogconsortium.uk/wp-content/uploads/2021/01/Report-2_COG-UK_SARS-

115 CoV-2-Mutations.pdf). It is not clear how these strains acquired so many changes without clear

116 intermediate variants. It has however been speculated, with some evidence, that they may have

117 evolved in immunosuppressed chronically infected patients (Kemp et al., 2021) who support

118 high levels of viral replication for months and may be treated with immune plasma or

119 monoclonal antibodies which may drive selection of variants displaying mutations that evade

120 antibody responses.

121

122 Of most concern are changes in the RBD. P.1 has three: K417T, E484K and N501Y, B.1.351

123 also has three: K417N, E484K and N501Y whereas, B.1.1.7 contains the single N501Y

124 mutation. All of these changes have the potential to modulate ACE2/RBD affinity potentially

125 leading to increased transmissibility, for which there is now good evidence in B.1.1.7. In

126 addition, these mutated residues also have the potential to modulate neutralization of SARS-

127 CoV-2 by naturally or vaccine induced antibody responses.

128

129　In this paper we examine an isolate of P.1 cultured from a throat swab taken from an infected

130　patient in Manaus, Brazil in December 2020 and compare its interactions with serum and

131　antibodies with those of three other viruses, an early isolate, B.1.1.7 and B.1.351. We test the

132　ability of immune sera induced by infection with early strains of SARS-CoV-2 (Dejnirattisai

133　et al., 2021), or by vaccination with the Oxford-AstraZenca or Pfizer-BioNTech vaccines to

134　neutralize P.1 (Supasa et al., 2021;Zhou et al., 2021). We see a reduction in the neutralizing

135　capacity of immune serum to P.1 similar to the reduction seen with B.1.1.7, but not as severe

136　as that seen with B.1.351 (Zhou et al., 2021). We demonstrate an increased affinity of P.1 RBD

137　for ACE2 and investigate the structural basis of this through crystallography. We also study

138　neutralization by a panel of potent monoclonal antibodies which block RBD/ACE2 interaction

139　and provide a crystallographic solution of how one potent antibody, mAb 222, of the panel

140　(Dejnirattisai et al., 2021) which contacts both K417 and N501, is resistant to the 501Y and

141　417T/N mutations found in the P.1/B1.351 strains. We dissect the basis for this via a series of

142　high resolution structures of RDB-Fab complexes and based on this restore neutralization of

143　certain antibodies by swapping the light chain. Finally, we bring together data on P.1, B.1.351

144　and B.1.1.7 and attempt to interpret the different effects these have upon the neutralizing

145　capacity of serum generated to early SARS-CoV-2 strains.

146

147　**Results**

148

149　*The P.1 lineage*

150　P.1 was first reported in December 2020 from Manaus in Amazonas province of Northern

151　Brazil (Faria et al., 2021). A large first wave of infection was seen in Manaus in March-June

152　2020 and by October around 75% of individuals from the region are estimated to have been

153　infected, representing a very high attack rate. A second large wave of infection began in

154   December 2020 leading to further hospitalizations. This second wave corresponded with the

155   rapid emergence of P.1, not seen before December when it was found in 52% of cases, rising

156   to 85% by January 2021 (**Figure S1**).

157

158   P.1 contains multiple changes compared to B.1.1.28 and P.2 which had been previously

159   circulating in Brazil (Faria et al., 2021). Compared to the Wuhan sequence P.1 contains the

160   following mutations: L18F, T20N, P26S, D138Y, R190S in the NTD, K417T, E484K, N501Y

161   in the RBD, D614G and H655Y at the C-terminus of S1 and T1027I, V1176F in S2. The

162   position of the changes seen in P.1 compared with those found in B.1.1.7 and B.1.351 together

163   with a representation on where they occur on the full spike protein and RBD are shown in

164   **Figure 1**. Mutations K417T, E484K, N501Y in the ACE2 interacting surface are of the greatest

165   concern because of their potential to promote escape from the neutralizing antibody response

166   which predominately targets this region (**Figure 1D)** (Dejnirattisai et al., 2021). We searched

167   the COVID-19 genomics UK (COG-UK) (Tatusov et al., 2000) and the global initiative on

168   sharing avian influenza data (GISAID) (https://www.gisaid.org) databases. A small number

169   of sequences including the K417T mutation, inclusive of the P.1 lineage, have been observed

170   in sequencing from Japan, France, Belgium, Italy, the Netherlands and Colombia (**Figure S1**).

171

172   It is noteworthy that P.1, B.1.1.7 and B.1.351 have accrued multiple mutations in the NTD, in

173   B.1.1.7 there are two deletions Δ69-70 and Δ144, in B.1.351 four amino acid changes and the

174   Δ242–244 deletion, while in P.1 there are 6 amino acid changes in the NTD but no deletions.

175   Of note, two of the NTD changes in P.1 introduce N-linked glycosylation sequons T20N (TRT

176   to NRT) and R190S (NLR to NLS, **Figure 1E)**. The NTD, in the absence of these changes,

177   reasonably well populated with glycosylation sites, indeed it has been suggested that a single

178   bare patch surrounded by N-linked glycans glycans attached at N17, N74, N122, and N149

179   defines a 'supersite' limiting where neutralizing antibodies can attach to the NTD (Cerutti et

180   al., 2021). Residue 188 is somewhat occluded whereas residue 20 is highly exposed, is close

181   to the site of attachment of neutralizing antibody 159 (Dejnirattisai et al., 2021) and impinges

182   on the proposed NTD supersite.

183

184   *The effects of RBD mutations on ACE2 affinity.*

185   We have previously measured the affinity of RBD/ACE2 interaction for Wuhan, B.1.1.7

186   (N501Y) and B.1.351 (K417N, E484K, N501Y) RBDs. N501Y increased affinity 7-fold and

187   the combination of 417, 484 and 501 mutations further increased affinity (19-fold compared to

188   Wuhan). Here we have expressed P.1 RBD (K417T, E484K, N501Y). The K_D for the

189   P.1/ACE2 interaction is 4.8 nM with Kon=1.08E5/Ms, Koff=5.18E-4/s (**Figure S2**, Methods),

190   showing that binding to P.1 is essentially indistinguishable from B.1.351 (4.0 nM).

191

192   To better understand RBD-ACE2 interactions we determined the crystal structure of the RBD-

193   ACE2 complex at 3.1 Å resolution (Methods, **Table S1**). As expected the mode of RBD-ACE2

194   engagement is essentially identical for P.1 and the original Wuhan RBD sequence (**Figure**

195   **2A**). The RMS deviation between the 791 Ca positions is 0.4 Å, similar to the experimental

196   error in the coordinates, and the local structure around each of the three mutations is conserved.

197   Nevertheless, calculation of the electrostatic potential of the contact surfaces reveals a marked

198   change, with much greater complementarity for the P.1 RBD consistent with higher affinity.

199   (**Figure 2B,C,D**).

200

201   Residue 417 lies at the back of the RBD neck (our RBD anatomy follows Dejnirattisai et al.,

202   2021) and in the original SARS-CoV-2 is a lysine residue which forms a salt-bridge with D30

203   of ACE2 (**Figure 2E**). The threonine of P.1 RBD no longer forms this interaction and the gap

created is open to solvent, so there is no obvious reason why the mutation would increase

affinity for ACE2, and this is consistent with directed evolution studies (Zahradník et al., 2021)

where this mutation was rarely selected in RBDs with increased affinity for ACE2.

Residue 484 lies atop the left shoulder of the RBD and neither the original Glu nor the Lys of

P1 make significant contact with ACE2, nevertheless the marked change in charge

substantially improves the electrostatic complementarity (**Figure 2F,G**), consistent with

increased affinity.

Residue 501 lies on the right shoulder of the RBD and the change from a relatively short Asn

sidechain to the large aromatic Tyr allows for favourable ring stacking interactions consistent

with increased affinity (**Figure 2H**).

Binding of P.1 RBD by potent human monoclonal antibodies

We have previously described a large panel of monoclonal antibodies generated from patients

infected with early strains of SARS-CoV-2, before the emergence of B.1.1.7 (Dejnirattisai et

al., 2021). From this panel we have selected 20 potent antibodies which have focus reduction

neutralization 50% (FRNT50) values <100ng/ml, 19 of these mAbs have an epitope on the

RBD and all of these block ACE2/RBD interaction, whilst mAb 159 binds the NTD. We used

biolayer interferometry (BLI) to measure the affinity of the RBD-binding antibodies and found

that compared to Victoria (SARS-CoV-2/human/AUS/VIC01/2020), an early isolate of SARS-

CoV-2, which has a single change S247R in S compared to the Wuhan strain (Seemann et al.,

2020; Caly et al., 2020) monoclonal antibody binding was significantly impacted with a

number showing complete knock-out of activity (**Figure 2I**). The results with P.1 showed a

greater impact compared to B.1.1.7 but similar to B.1.351 (Zhou et al., 2021), this is expected

since both contain mutation of the same 3 residues in the RBD, only differing at position 417, K417N in B.1.351 and K417T in P.1. The localization of the impact on binding is shown in **Figure 2J** and reflects direct interaction with mutated residues. Of note is mAb 222 which maintains binding potency across all variants despite adjacency to mutated residues, as discussed below.

Neutralization of P.1 by potent human monoclonal antibodies

Using the same set of 20 potent antibodies neutralization was measured by a focus reduction neutralization test (FRNT) and compared with neutralization of Victoria and variants B.1.1.7 and B.1.351. Compared to Victoria neutralization by the monoclonal antibodies was significantly impacted by P.1, with 12/20 showing >10-fold reduction in FRNT50 titre and a number showing complete knock out of activity (**Figure 3A Table S2**). The results with P.1 showed a greater impact compared to B.1.1.7 but were as expected similar to those with B.1.351 (Zhou et al., 2021). There is good correlation between the negative impact on neutralization and on RBD-affinity (**Figure 2J**).

Reduced neutralization of P.1 by monoclonal antibodies being developed for clinical use.

A number of potent neutralizing antibodies are being developed for clinical use either therapeutically of prophylactically (Ku et al., 2021;Baum et al., 2020;Kemp et al., 2021). We performed neutralization assays against P.1 using antibodies S309 Vir (Pinto et al., 2020), AZD8895, AZD1061 and AZ7442 (a combination of AZD8895 and AZD1061) AstraZeneca, REGN10987 and REGN10933 Regeneron, LY-CoV555 and LY-CoV16 Lilly and ADG10, ADG20 and ADG30 from Adagio (**Figure 3B**). The affinity of binding to P.1 RBD was also investigated by BLI for the Regeneron and AstraZeneca antibodies and the results (**Figure 2I**) parallel closely the neutralization results. Neutralization of both Lilly antibodies was severely

254   impacted with LY-CoV16 and LY-CoV555 showing almost complete loss of neutralization of

255   P.1 and B.1.351 while LY-CoV16 also showed marked reduction in neutralization of B.1.1.7.

256   There was also escape from neutralization of P.1 by REGN10933 and a modest reduction in

257   neutralization of P.1 by AZD8895, while AZD1061 and AZD 7442 showed equal

258   neutralization of all SARS-CoV-2 variants. The three Adagio antibodies neutralized all variants

259   with all reaching a plateau at 100% neutralization and interestingly, ADG30 showed a slight

260   increase of neutralization of P.1. S309 Vir was largely unaffected although for several viruses,

261   including P.1, the antibody failed to completely neutralize, conceivably reflecting incomplete

262   glycosylation at N343, since the sugar interaction is key to binding of this antibody N343 (Pinto

263   et al., 2020). The escape from REGN10933 and LY-CoV555 mirrors that of other potent

264   antibodies (including 316 and 384 in our set) which make strong interactions with residues

265   484-486 and are severely compromised by the marked change E484K, whereas LY-CoV016,

266   an IGHV3-53 mAb, is affected by changes at 417 and 501. The abrogation of the Lilly Ly-

267   CoV-16 and LyCoV-555 antibodies reflects the observation of Starr et al. (Starr et al.,

268   2021)(Greaney et al., 2021) that LY-CoV555 is sensitive to mutation at residue 384 and LY-

269   CoV16 is sensitive to changes at 417.

270

271   *Reduced neutralization by an NTD-binding antibody*

272   The neutralization titre of NTD-binding mAb159, was 133-fold reduced on P.1 compared to

273   Victoria with only 64% neutralization at 10μg/ml (**Figures 3A**). Although P.1 does not harbor

274   deletions in the NTD like B.1.1.7 (Δ69−70, Δ144) or B.1.351 (Δ242−244), it is clear that the 6

275   NTD mutations in P.1 (L18F, T20N, P26S, D138Y, R190S) disrupt the epitope for mAb159

276   (**Figure 4A**) (Dejnirattisai et al., 2021;Supasa et al., 2021). It is possible that the failure of this

277   antibody to achieve complete neutralization could be due to partial glycosylation at residue 20,

278   which is some 16 Å from bound Fab 159, however the L18F mutation is even closer and likely

279 to diminish affinity (**Figure 4A**). Since it has been proposed that there is a single supersite for

280 potent NTD binding antibodies we would expect the binding of many of these to be affected

281 (Cerutti et al., 2021).

282

283 *Reduced neutralization by VH3-53 public antibodies*

284 Five of the potent monoclonal antibodies used in this study (150, 158, 175, 222 and 269),

285 belong to the VH3-53 family and a further 2 (out of 5 of this family) belong to the almost

286 identical VH3-66, and the following discussion applies also to these antibodies. The binding

287 sites for these have been described (Dejnirattisai et al., 2021). The large majority of these

288 antibodies attach to the RBD in a very similar fashion. These motifs recur widely, VH3-53 are

289 the most prevalent deposited sequences and structures for SARS-CoV-2 neutralizing

290 antibodies. Their engagement with the RBD is dictated by CDR-H1 and CDR-H2 whilst the

291 CDR-H3 is characteristically short and makes rather few interactions (Yuan et al., 2020; Barnes

292 et al., 2020;Dejnirattisai et al., 2021). We have previously solved the structures of mAbs 150,

293 158 and 269 (**Figure 4B**) which show that whilst there are no contacts with residue 484, there

294 are interactions of CDR-H3 with K417 and CDR-L1 with N501, meaning that binding and

295 neutralization by VH3-53 antibodies would be predicted to be compromised by the N501Y

296 change in variant viruses B.1.1.7, B.1.351 and P.1, whilst the additional change at 417 in P.1

297 (K417T) and B.1.351 (K417N) might be expected to have an additive effect (Dejnirattisai et

298 al., 2021).

299

300 In practice, changes in the light chain and CDR-H3 between members of this family mean that

301 the story is more complex. Thus, neutralization of P.1 by 175 and 158 is severely impacted and

302 neutralization of P.1 by 269 is almost completely lost. However, for 150 P.1 neutralization is

303 less compromised than for B.1.351 (Zhou et al., 2021), whilst for 222 neutralization is

304 completely unaffected by the changes in P.1 and indeed all variants (**Figure 3A**).

305

306 We measured the affinity of 222 for both P.1 (K_D = 1.92±0.01 nM) and Wuhan RBD (K_D =

307 1.36±0.08 nM) showing no reduction in the strength of interaction despite the changes

308 occurring in the putative binding site for P.1 (**Table S2**).

309

310 To understand how 222 is able to still neutralize P.1 we solved the crystal structures of six

311 ternary complexes of 222 in complex with the RBDs for (i) the original virus, and bearing

312 mutations (ii) K417N; (iii) K417T; (iv) N501Y; the 417, 484 and 501 changes characteristic

313 of B.1.351 (v) and P.1 (vi). All crystals also contained a further Fab, EY6A as a crystallization

314 chaperone (Zhou et al., 2020), were isomorphous and the resolution of the structures ranged

315 from 1.95 to 2.67 Å, **Figure 4C,D**, Methods, **Table S1**. As expected, the structures are highly

316 similar with the binding pose of 222 being essentially identical in all structures (pairwise

317 RMSD in Cα atoms between pairs of structures are ~0.2-0.3 Å for all residues in the RBD and

318 Fv region of mAb 222, **Figure 4D**).

319

320 In the original virus residue 417 makes a weak salt bridge interaction with heavy chain CDR3

321 residue E99. Mutation to either Asn or Thr abolishes this and there is little direct interaction,

322 although there are weak (~3.5 Å) contacts to heavy chain Y52 and light chain Y92 (**Figure**

323 **4E**). However, a buffer molecule/ion rearranges to form bridging interactions and this may

324 mitigate the loss of the salt bridge, in addition the original salt bridge is weak and its

325 contribution to binding may be offset by the loss of entropy in the lysine sidechain. We note

326 that CDR-H3 of 222, at 13 residues is slightly longer than found in the majority of potent VH3-

327 53 antibodies, however this seems unlikely to be responsible for the resilience of 222, rather it

seems that there is little binding energy in general from the CDR3-H3, since most of the binding energy contribution of the heavy chain comes from CDR-H1 and CDR-H2 which do not interact with RBD residue 417, meaning that many VH3-53 antibodies are likely to be resilient to the common N/T mutations (**Figure 4B**).

Residue 501 makes contact with CDR-L1 of mAb 222 (**Figure 4D,F**), however the interaction, with P30 is probably slightly strengthened by the N501Y mutation which provides a stacking interaction with the proline, conferring resilience. This is in contrast to the situation with most other VH3.53 antibodies where direct contacts confer susceptibility to escape by mutation to Tyr (**Figures 2I,J and 3A**) (Supasa et al., 2021;Zhou et al., 2021).

The 222 light chain can rescue neutralization by other VH3-53 mAbs

Reasoning that the relative robustness of mAb 222 to common variants (P.1, B.1.1.7 and B.1.351) compared to other VH3-53 antibodies stems from the choice of light chain we modelled the 222LC with the heavy chains of other VH3-53 antibodies to see if they might be compatible **(Figure 4G)**. The result was striking, it appeared that there would likely be no serious steric clashes. This contrasted with the numerous clashes seen when we docked the light chains of other VH3-53 antibodies onto the heavy chain of 222 (**Figure 4G,H**). This suggests that the 222 light chain might be an almost universal light chain for these 3-53 antibodies and could confer resilience to P.1, B.1.1.7 and B.1.351 variants. This led us to create chimeric antibodies containing the 222LC combined with the HC of the other VH3-53 mAbs 150, 158, 175 and 269. In all cases, chimeric antibodies expressed well and we performed neutralization assays against Victoria, B.1.1.7, B.1.351 and P.1 viruses **(Figure 5)**. For B.1.1.7 neutralization of 150HC/222LC, 158HC/222LC and 269HC/222LC was restored to near the level seen on Victoria, whilst 175HC/222LC could not fully neutralize B.1.1.7. For B.1.351

353 and P.1 the activity of mAbs 150 and 158 was restored in chimeras containing the 222LC, with

354 the 150HC/222LC showing 50-fold greater potency against B.1.351 (7ng vs 350 ng/ml) and

355 13-fold greater potency against P.1 (3ng vs 40 ng/ml) than native 150. With an FRNT50 of

356 3ng/ml 150HC/222LC was the most potent antibody tested against P.1.

357

358 *Neutralization of P.1 by convalescent plasma*

359 We collected convalescent plasma samples from a cohort of volunteers who had suffered from

360 SARS-CoV-2 infection evidenced by a positive diagnostic PCR. Samples were collected

361 during the convalescent phase, 4-9 weeks following infection, all samples were taken during

362 the first wave of infection in the UK, prior June 2020 and well before the emergence of the

363 B.1.1.7 variant. We have also collected plasma from volunteers recently infected with B.1.1.7

364 as demonstrated by viral sequencing or S gene drop out from the diagnostic PCR (Dejnirattisai

365 et al., 2021;Supasa et al., 2021).

366

367 Neutralization of P.1 was assessed by FRNT on 34 convalescent samples **(Figure 6A Table**

368 **S3A)**. P.1 neutralization curves are displayed alongside neutralization curves for Victoria,

369 together with B.1.1.7 and B.1.351. P.1 geometric mean neutralization titres were reduced 3.1-

370 fold compared to Victoria (p< 0.0001). This reduction was similar to B.1.1.7 (2.9-fold) and

371 considerably less than B.1.351 (13.3-fold) **(Figure 6C)**. When using plasma from individuals

372 infected with B.1.1.7 we saw only modest (1.8-fold p=0.0039) reductions in neutralization

373 comparing P.1 with Victoria **(Figure 6B and D Table S3B)**.

374

375 *Neutralization of P.1 by vaccine serum*

376 We next performed neutralization assays using serum collected from individuals who had

377 received either the BNT162b2 Pfizer-BioNTech or ChAdOx1 nCoV-19 Oxford-AstraZeneca

378   vaccine **Figure 7** (Supasa et al., 2021;Zhou et al., 2021). For the Pfizer BioNTech vaccine

379   serum was collected 4-14 days following the second dose of vaccine administered three weeks

380   after the first dose (n=25). For the Oxford-AstraZeneca vaccine serum was taken 14 or 28 days

381   following the second dose which was administered 8-14 weeks following the first dose (N=25).

382   Geometric mean neutralization titres against P.1 were reduced 2.6-fold (p<0.0001) relative to

383   the Victoria virus for the Pfizer-BioNTech vaccine serum **Figure 7A,C** and 2.9-fold

384   (P<0.0001) for the Oxford-AstraZeneca vaccine **Figure 7B,D Table S4.**

385

386   Neutralization titres against P.1 were similar to those against B.1.1.7 and only a minority of

387   samples failed to reach 100% neutralization at 1:20 dilution of serum, considerably better than

388   neutralization of B.1.351, where titres were reduced 7.6-fold and 9-fold for the BNT162b2

389   Pfizer and ChAdOx1 nCoV-19 AstraZeneca vaccines respectively.

390

391   **Discussion**

392

393   Large scale viral sequencing programmes have uncovered a spectrum of mutations containing

394   changes at many locations in the SARS-CoV-2 genome in correspondence with the concept of

395   viral quasispecies (Domingo and Perales, 2019). Mutations in S are of particular concern as S,

396   through the RBD, directs cellular tropism and in addition is the target for the neutralizing

397   antibody response. Mutations in S could therefore enhance viral fitness by increasing affinity

398   to ACE2 or provide escape from the antibody response induced by natural infection or

399   vaccination.

400

401   P.1 contains 12 individual changes spread throughout S with three changes in the RBD. In this

402   paper we demonstrate an increase in affinity of interaction for P.1 RBD with ACE2 to an

403 equivalent degree as that observed for B.1.351 with binding somewhat tighter than for B.1.1.7.

404 It seems conceivable that this increase in receptor affinity may drive increased virus

405 transmissibility, allowing the three variants to become dominant strains in the regions where

406 they emerged (Zhou et al., 2021;Supasa et al., 2021).

407

408 The ACE2 interacting surface of RBD is a small 25 amino acid patch at the apex of S and is

409 under extreme selection pressure as it not only mediates interaction with the cellular receptor

410 but is also the site of binding for a major class of neutralizing antibodies that block the

411 interaction of ACE2 with the RBD (Zost et al., 2020;Kreye et al., 2020;Wu et al., 2020;Yuan

412 et al., 2020). (Dejnirattisai et al., 2021). Recently, two elegant unbiased approaches have been

413 used to assess the influence of mutation on the ACE2/RBD binding affinity or the ability of

414 RBD mutations to evade the polyclonal antibody response. Firstly, a yeast display approach

415 was used to generate RBD mutants with enhanced ACE2 binding. Amongst a number of

416 mutations selected were the very same positions found in the recent variants of concern, namely

417 E484K and N501Y, and less frequently changes at residue 417 were also observed (Zahradník

418 et al., 2021). Multiple rounds of selection led to the emergence of mutant RBDs with 600-fold

419 higher affinity to ACE2, in the low picomolar range. In a second approach, polyclonal anti-

420 SARS-CoV-2 serum was used to select mutant RBD from a yeast display library which showed

421 reduced antibody binding (Greaney et al., 2021). This approach led to the identification of a

422 number of potential antibody escape mutants, amongst them E484 which is likely responsible

423 for a proportion of the escape from antibody neutralization we describe for P.1.

424

425 What is driving the emergence of the new strains is difficult to determine, the emergence of

426 B.1.1.7 occurred on the background of relatively low population immunity and may have been

427 primarily driven by increased transmissibility. The emergence of B.1.351 occurred on the

428 background of around 30% seropositivity in South Africa and P.1 on the background of an

429 estimated 75% seropositivity in Manaus Brazil (Faria et al., 2021). It seems possible that

430 selection of P.1 and B.1.351 may have been in part driven by immune escape, however until

431 methods are developed to screen at a population level for the frequency of reinfection, it is not

432 possible to determine this, especially as reinfection may lead to more mild or asymptomatic

433 disease.

434

435 Because P.1 and B.1.351 contain very similar changes in the RBD it might be assumed that

436 neutralization of both would be similarly affected. This was indeed the case for neutralization

437 by monoclonal antibodies directed at the RBD, where there was substantial escape from many

438 antibodies in our panel or from antibodies being developed for clinical use. However,

439 neutralization of P.1 was not compromised as severely as neutralization of B.1.351, when using

440 convalescent or vaccine serum induced by earlier SARS-CoV-2 strains(Zhou et al., 2021).

441 Using convalescent serum B.1.351 showed 13-fold reduction in neutralization compared to

442 Victoria whilst P.1 was only reduced 3.1-fold, comparable to the reduction seen with B.1.1.7,

443 which only harbours the single N501Y change in the RBD (Zhou et al., 2021;Supasa et al.,

444 2021). Similarly, neutralization of P.1 by vaccine serum was less impacted than neutralization

445 of B.1.351 meaning that vaccination with Wuhan S will likely provide some protection against

446 P.1. There is now clinical evidence that the ChAdOx1 nCoV-19 Oxford-AstraZeneca and

447 NVX-CoV2373 Novavax vaccines provide protection from B.1.1.7 (Emary et al.,

448 2021;Mahase, 2021). For B.1.351 both the Novavax

449 (https://www.webmd.com/vaccines/covid-19-vaccine/news/20210131/vaccine-not-as-

450 effective-against-south-african-variant) and Janssen vaccine

451 (https://www.reuters.com/article/us-health-coronavirus-vaccines-johnson-j-

452 idUSKBN29Z0F0) saw a marked decrease in efficacy against B.1.351, but still showed >50%

protection against moderate and severe disease, whilst in a Phase II trial, ChAdOx1 nCoV-19

efficacy against mild to moderate disease caused by B.1.351 was 10.4% (95% CI: –76.8; 43.8),

but efficacy against severe disease could not be assessed in this study (Madhi et al., 2021).

The reason for the differences in neutralization of B.1.351 and P.1 by immune serum are not

immediately clear, but presumably reflect the difference in the mutations introduced outside

the RBD. In addition to our mAb 159 a number of potent neutralizing mAbs have been reported

that map to the NTD (Cerutti et al., 2021), and this domain has multiple mutations in all three

major variant strains: B.1.1.7 has two deletions, B.1.351 has a deletion and four substitutions

and P.1 has 6 amino acid substitutions, including the creation of two N-linked glycan sequons

(**Figure 1 A-C**). Comparison of neutralization of pseudoviruses expressing only the three RBD

mutations (K417N E484K N501Y) of B.1.351 with pseudovirus expressing the full suite of

mutations in B.1.351 spike show that the non-RBD changes substantially increase escape from

neutralization (Wibmer et al., 2021;Dejnirattisai et al., 2021;Wang et al., 2021). The changes

in the NTD of the major variants are far less consistent than those found in the RBD, and there

are no strong trends in electrostatic properties (**Figure 1A-C**). It therefore remains unclear what

the drivers are for these changes, although one or more of immune escape, co-receptor binding,

and modulation of RBD dynamics affecting presentation of the receptor binding site are

plausible. Nonetheless, it seems likely that these changes are largely responsible for the non-

RBD component of neutralization variation between strains.

A number of public antibody responses have been reported for SARS-CoV-2, principal

amongst these being VH3-53/VH3-66 and VH1-58 (VH3-30 is also found but the antibodies

are not potent neutralizers) (Yuan et al., 2020;Barnes et al., 2020; Dejnirattisai et al., 2021).

We have previously shown that mixing heavy and light chains from antibodies within VH1-58

478 can increase the neutralization titre by 20-fold from the parent antibodies (chimera of 253HC

479 with 55LC or 165LC) (Dejnirattisai et al., 2021). Here we have shown that chimeras created

480 amongst the VH3-53 antibodies using the 222LC are able to confer broad neutralization to

481 antibodies which have reduced neutralization capacity against the viral variants. Furthermore,

482 the chimera of 150HC with 222LC achieved 13 and 3-fold increases in neutralization titre

483 compared to the parental 150 and 222 mAb respectively. Creation of such antibody chimeras

484 amongst other anti-SARS-CoV2 antibodies may similarly lead to the discovery of more

485 antibodies with enhanced activity. This also suggests that highly effective natural responses

486 against all three variants, and common cross-protective responses, will be found.

487

488 The recent emergence of a number of variants of concern has led to efforts to design new

489 vaccines which will be able to protect against the viral variants. Exactly which variants or

490 sequences should be selected is difficult to determine in what is likely to be an evolving

491 situation, as vaccine induced herd immunity increases the selection pressure for immune

492 escape. Based on the results reported here the South African B.1.351 is the variant of greatest

493 concern giving the largest reductions in neutralization titres and evidence of complete failure

494 to neutralize in some cases and we believe developing vaccine constructs to B.1.351 to be the

495 greatest priority.

496

497 In summary, we demonstrate that P.1 can escape neutralization by a number of monoclonal

498 antibodies including some being developed for prophylactic or therapeutic use, while other

499 antibodies with epitopes away from the mutated RBD residues retain broad neutralization.

500 Thus S309/AZD1061/REGN10987/ADG10/ADG20/ADG30 showed little to no reduction

501 (<4-fold) in neutralization activity across the three variants, consistent with their previously

502 described broadly neutralizing activities across clade I sarbecoviruses.

503

504 In contrast to B.1.351, neutralization of P.1 does not show such a substantial reduction by

505 polyclonal serum induced by natural infection or vaccination and there is no evidence of

506 widespread escape. Despite the reduction in neutralization titres it is hoped that immunization

507 with vaccines designed against parent/ancestral strains will provide protection from P.1.

508

509 **Limitations of the study**

510

511 The in vitro FRNT assays we report here do not measure the effect of complement or antibody

512 dependent cell mediated cytotoxicity which may enhance neutralization in vivo. The role that

513 T cells play in immunity to SARS-CoV-2 and in particular protection from severe disease is

514 unknown and worthy of investigation, but recent findings suggest that CD4 and CD8 T cell

515 responses raised to ancestral strains are minimally impacted by the variants (Alison Tarke et

516 al., 2021;Skelly et al., 2021). It will be interesting to determine the directionality of

517 neutralization between the different variant viruses and naturally acquired antibody responses

518 to them. For instance, there is some suggestion in this report that plasma induced by B.1.1.7 is

519 better able to neutralize B.1.351 and P.1. Measuring neutralization of viral variants by B.1.351

520 and P.1 serum will give a better idea of cross protection against the other strains.

Figure Legends

Figure 1. Mutational landscape of P.1. Schematic showing the locations of amino acid substitutions in (A) P.1, (B) B.1.351 and (C) B.1.1.7 relative to the Wuhan SARS-CoV-2 sequence. Under the structural cartoon is a linear representation of S with changes marked on. Where there is a charge change introduced by mutations the change is coloured (red if the change makes the mutant more acidic/less basic, blue more basic/less acidic). (D) Depiction of the RBD as a grey surface with the location of the three mutations K417T, E484K and N501Y (magenta) the ACE2 binding surface of RBD is coloured green. (E) locations of N-linked glycan (red spheres) on the spike trimer shown in a pale blue surface representation, the two new sequons found in P.1 are marked blue.

Figure 2. Comparison of WT RBD/ACE2 and P.1 RBD/ACE2 complexes. (A) Comparison of P.1 RBD/ACE2 (grey and salmon) with WT RBD/ACE2 (blue and cyan)

23

603   (PDB ID 6LZG) by overlapping the RBDs. The mutations in the P.1 RBD are shown as

604   sticks. (B), (C) Open book view of electrostatic surface of the WT RBD/ACE2 complex, and

605   (C), (D) of the P.1 RBD/ACE2 complex. Note the charge difference between the WT and the

606   mutant RBDs. The charge range displayed is ±5 kJ/mol. (E) The K417 of the WT RBD forms

607   a salt bridge with D30 of ACE2. (F) and (G) Effect of E484K mutation on the electrostatic

608   surface (H) Y501 of the P.1 RBD makes a stacking interaction with Y41 of ACE2. (H) K_D of

609   RBD/mAb interaction measured by BLI for RBDs of Victoria, B.1.1.7, P.1 and B.1.351 (left

610   to right) (I) BLI data mapped onto the RBD using the method described (Dejnirattisai *et al.*,

611   2021). Front and back views of the RBD are shown. In the left pair the spheres represent the

612   antibody binding sites coloured according to the ratio (K_DP.1/K_DWuhan). For white the ratio

613   is 1, for red it is <0.1 (i.e. at least 10-fold reduction) black dots refer to mapped antibodies

614   not included in this analysis, dark green RBD ACE2 binding surface, yellow mutated K417T,

615   E484K, N501Y. For the right pair atoms are coloured according to the ratio of neutralisation

616   titres (IC_{50}B.1.351/IC_{50}Victoria), for white the ratio is 1, for red it is <0.01 (i.e. at least 100-

617   fold reduction). Note the strong agreement between K_D and IC_{50}. 269 is very strongly

618   affected and is close to the IGHV3-53 and IGHV3-66 antibodies (*e.g.* 222).

619

620   **Figure 3. Neutralization of P.1 by monoclonal antibodies.** (A) Neutralization of P.1 by a

621   panel of 20 potent human monoclonal antibodies. Neutralization was measured by FRNT,

622   curves for P.1 are superimposed onto curves for Victoria, B.1.1.7 and B.1.351 as previously

623   reported (Supasa et al., 2021;Zhou et al., 2021). FRNT50 titres are reported in Table S2

624   Neutralization curves for monoclonal antibodies in different stages of development for

625   commercial use. (B) Shows equivalent plots for the Vir, Regeneron, AstraZeneca, Lilly and

626   Adagio antibodies therapeutic antibodies.

630 back surfaces of the RBD bound to a typical VH3-53. P1 mutations in the RBD are highlighted

631 in dark green and labelled. In this group, monoclonal antibody 222 has a slightly longer CDR3.

632 Sequences of VH3-53 CDR1-3 heavy and light chains are also shown. (C) Crystal structure of

633 P1 RBD, 222 Fab and EY6A Fab (Zhou et al., 2020). (D) Close up of 222 CDRs interacting

634 with the RBD (grey) mutations are highlighted in yellow on the green ACE2 interface. (E)

635 K417 interactions with Fab 222 (F) N501 interactions with Fab 222. (G), (H) Fab 222 chimera

636 models.

637

638 **Figure 5. Neutralization curves of VH3-53 chimeric antibodies.** Neutralization curves of

639 Victoria, B.1.1.7, B.1.351 and P.1. Left hand column; neutralization curves using the native

640 antibodies 222, 150, 158, 175 and 269. Right hand column; neutralization curves for chimeric

641 antibodies, the heavy chains of 150, 158, 175 and 269 are combined with the light chain of

642 222, native 222 is used as the control. FRNT50 titres are given in Table S2.

643

644 **Figure 6 Neutralization of P.1 by convalescent plasma.** Plasma (n=34) was collected from

645 volunteers 4-9 weeks following SARS-CoV-2 infection, all samples were collected before June

646 2020 and therefore represent infection before the emergence of B.1.1.7 in the UK. (A)

647 Neutralization of P.1 was measured by FRNT, comparison is made with neutralization curves

648 for Victoria, B.1.1.7 and B.1.351 that we have previously generated (Zhou et al., 2021;Supasa

649 et al., 2021). (B) Neutralization of P.1 by plasma taken from volunteers who had suffered

650 infection with B.1.1.7 as evidenced by sequencing or S-gene drop out by diagnostic PCR.

651 Samples were taken at varying times following infection. (C-D) Comparison of FRNT50 titres

652 between Victoria and P.1, data for B.1.1.7 and B.1.351 are included for comparison and, the

653 Wilcoxon matched-pairs signed rank test was used for the analysis and two-tailed P values

654 were calculated, geometric mean values are indicated above each column.

655

656 **Figure 7 Neutralization of P.1 by vaccine serum.** (A) Pfizer vaccine, serum (n=25) was taken

657 7-17 days following the second dose of the Pfizer-BioNTech vaccine. FRNT titration curves

658 are shown with Victoria, B.1.1.7 and B.1.351 as comparison (Supasa et al., 2021;Zhou et al.,

659 2021). (B) AstraZenca vaccine, serum was taken 14 or 28 days following the second dose of

660 the Oxford-AstraZeneca vaccine (n=25). (C-D) Comparison of FRNT50 titres for individual

661 samples for the Pfizer and AstraZeneca vaccine between Victoria, B.1.1.7, B.1.351 and P.1,

662 the Wilcoxon matched-pairs signed rank test was used for the analysis and two-tailed P values

663 were calculated, geometric mean values are indicated above each column.

677 the findings of this study are available from the corresponding authors on request.

678

EXPERIMENTAL MODEL AND SUBJECT DETAILS

Viral stocks

SARS-CoV-2/human/AUS/VIC01/2020 (Caly et al., 2020), SARS-CoV-2/B.1.1.7 and SARS-CoV-2/B.1.351 were provided by Public Health England, P.1 from a throat swab from Brazil were grown in Vero (ATCC CCL-81) cells. Cells were infected with the SARS-CoV-2 virus using an MOI of 0.0001. Virus containing supernatant was harvested at 80% CPE and spun at 3000 rpm at 4 °C before storage at -80 °C. Viral titres were determined by a focus-forming assay on Vero cells. Victoria passage 5, B.1.1.7 passage 2 and B.1.351 passage 4 stocks were sequenced to verify that they contained the expected spike protein sequence and no changes to the furin cleavage sites. The P.1 virus used in these studies contained the following mutations: L18F, T20N, P26S, D138Y, R190S, K417T, E464K, N501Y, D614G, H655Y, T1027I, V1176F. Passage 1 P.1 virus was sequence confirmed and contained no changes to the furin cleavage site.

Bacterial Strains and Cell Culture

Vero (ATCC CCL-81) cells were cultured at 37 °C in Dulbecco's Modified Eagle medium (DMEM) high glucose (Sigma-Aldrich) supplemented with 10% fetal bovine serum (FBS), 2 mM GlutaMAX (Gibco, 35050061) and 100 U/ml of penicillin–streptomycin. Human mAbs were expressed in HEK293T cells cultured in UltraDOMA PF Protein-free Medium (Cat# 12-727F, LONZA) at 37 °C with 5% CO_2. *E.coli DH5α* bacteria were used for transformation of plasmids encoding wt and mutated RBD proteins. A single colony was picked and cultured in LB broth with 50 μg mL^{-1} Kanamycin at 37 °C at 200 rpm in a shaker overnight. HEK293T (ATCC CRL-11268) cells were cultured in DMEM high glucose (Sigma-Aldrich) supplemented with 10% FBS, 1% 100X Mem Neaa (Gibco) and 1% 100X L-Glutamine

702 (Gibco) at 37 °C with 5% CO_2. To express RBD, RBD K417T, E484K, N501Y, RBD K417N,

703 RBD K417T, RBD E484K and ACE2, HEK293T cells were cultured in DMEM high glucose

704 (Sigma) supplemented with 2% FBS, 1% 100X Mem Neaa and 1% 100X L-Glutamine at 37

705 °C for transfection.

706 *Participants*

707 Participants were recruited through three studies: Sepsis Immunomics [Oxford REC C,

708 reference:19/SC/0296]), ISARIC/WHO Clinical Characterisation Protocol for Severe

709 Emerging Infections [Oxford REC C, reference 13/SC/0149] and the Gastro-intestinal illness

710 in Oxford: COVID sub study [Sheffield REC, reference: 16/YH/0247]. Diagnosis was

711 confirmed through reporting of symptoms consistent with COVID-19 and a test positive for

712 SARS-CoV-2 using reverse transcriptase polymerase chain reaction (RT-PCR) from an upper

713 respiratory tract (nose/throat) swab tested in accredited laboratories. A blood sample was taken

714 following consent at least 14 days after symptom onset. Clinical information including severity

715 of disease (mild, severe or critical infection according to recommendations from the World

716 Health Organisation) and times between symptom onset and sampling and age of participant

717 was captured for all individuals at the time of sampling.

718

719 P.1 virus from throat swabs. The International Reference Laboratory for Coronavirus at

720 FIOCRUZ (WHO) as part of the national surveillance for coronavirus had the approval of the

721 FIOCRUZ ethical committee (CEP 4.128.241) to continuously receive and analyze samples of

722 COVID-19 suspected cases for virological surveillance. Clinical samples (throat swabs)

723 containing P.1 were shared with Oxford University, UK under the MTA IOC FIOCRUZ 21-

724 02.

725

726

Sera from Pfizer vaccinees

Pfizer vaccine serum was obtained 7-17 days following the second dose of the BNT162b2 vaccine. Vaccinees were Health Care Workers, based at Oxford University Hospitals NHS Foundation Trust, not known to have prior infection with SARS-CoV-2 and were enrolled in the OPTIC Study as part of the Oxford Translational Gastrointestinal Unit GI Biobank Study 16/YH/0247 [research ethics committee (REC) at Yorkshire & The Humber – Sheffield]. The study was conducted according to the principles of the Declaration of Helsinki (2008) and the International Conference on Harmonization (ICH) Good Clinical Practice (GCP) guidelines. Written informed consent was obtained for all patients enrolled in the study. Each received two doses of COVID-19 mRNA Vaccine BNT162b2, 30 micrograms, administered intramuscularly after dilution as a series of two doses (0.3 mL each) 18-28 days apart. The mean age of vaccines was 43 years (range 25-63), 11 male and 14 female.

AstraZeneca-Oxford vaccine study procedures and sample processing

Full details of the randomized controlled trial of ChAdOx1 nCoV-19 (AZD1222), were previously published (PMID: 33220855/PMID: 32702298). These studies were registered at ISRCTN (15281137 and 89951424) and ClinicalTrials.gov (NCT04324606 and NCT04400838). Written informed consent was obtained from all participants, and the trial is being done in accordance with the principles of the Declaration of Helsinki and Good Clinical Practice. The studies were sponsored by the University of Oxford (Oxford, UK) and approval obtained from a national ethics committee (South Central Berkshire Research Ethics Committee, reference 20/SC/0145 and 20/SC/0179) and a regulatory agency in the United Kingdom (the Medicines and Healthcare Products Regulatory Agency). An independent DSMB reviewed all interim safety reports. A copy of the protocols was included in previous publications (PMID: 33220855/PMID: 32702298).

752

753   Data from vaccinated volunteers who received two vaccinations are included in this paper.

754   Vaccine doses were either 5×10^{10} viral particles (standard dose; SD/SD cohort n=21) or half

755   dose as their first dose (low dose) and a standard dose as their second dose (LD/SD cohort

756   n=4). The interval between first and second dose was in the range of 8-14 weeks. Blood

757   samples were collected and serum separated on the day of vaccination and on pre-specified

758   days after vaccination e.g. 14 and 28 days after boost.

759

760

761   **METHOD DETAILS**

762   *Focus Reduction Neutralization Assay (FRNT)*

763   The neutralization potential of Ab was measured using a Focus Reduction Neutralization Test

764   (FRNT), where the reduction in the number of the infected foci is compared to a negative

765   control well without antibody. Briefly, serially diluted Ab or plasma was mixed with SARS-

766   CoV-2 strain Victoria or P.1 and incubated for 1 hr at 37 °C. The mixtures were then transferred

767   to 96-well**,** cell culture-treated, flat-bottom microplates containing confluent Vero cell

768   monolayers in duplicate and incubated for a further 2 hrs followed by the addition of 1.5%

769   semi-solid carboxymethyl cellulose (CMC) overlay medium to each well to limit virus

770   diffusion. A focus forming assay was then performed by staining Vero cells with human anti-

771   NP mAb (mAb206) followed by peroxidase-conjugated goat anti-human IgG (A0170; Sigma).

772   Finally, the foci (infected cells) approximately 100 per well in the absence of antibodies, were

773   visualized by adding TrueBlue Peroxidase Substrate. Virus-infected cell foci were counted on

774   the classic AID EliSpot reader using **AID ELISpot software.** The percentage of focus

775   reduction was calculated and IC_{50} was determined using the probit program from the SPSS

776   package.

778 *Cloning of ACE2 and RBD proteins*

779 The constructs of EY6A Fab, 222 Fab, ACE2, WT RBD, B.1.1.7 and B.1.351 mutant RBD are

780 the same as previously described (Dejnirattisai et al. 2021, Zhou et al., 2021, Supasa et al.,

781 2021). To clone RBD K417T and RBD K417N, primers of RBD K417T (forward primer 5'-

782 GGGCAGACCGGCACGATCGCCGACTAC-3' and reverse primer 5'-

783 GTAGTCGGCGATCGTGCCGGTCTGCCC) and primers of RBD K417N (forward primer

784 5'-CAGGGCAGACCGGCAATATCGCCGACTACAATTAC-3' and reverse primer 5'-

785 GTAATTGTAGTCGGCGATATTGCCGGTCTGCCCTG-3') were used separately, together

786 with two primers of pNEO vector (Forward primer 5'- CAGCTCCTGGGCAACGTGCT-3'

787 and reverse primer 5'- CGTAAAAGGAGCAACATAG-3') to do PCR, with the plasmid of

788 WT RBD as the template. To clone P.1 RBD, the construct of B.1.351 RBD was used as the

789 template and the primers of RBD K417T and of pNEO vector mentioned above were used to

790 do PCR. Amplified DNA fragments were digested with restriction enzymes AgeI and KpnI

791 and then ligated with digested pNEO vector. All constructs were verified by sequencing.

792

793 *Protein production*

794 Protein production was as described in Zhou et al. (Zhou et al., 2020). Briefly, plasmids

795 encoding proteins were transiently expressed in HEK293T (ATCC CRL-11268) cells. The

796 conditioned medium was dialysed and purified with a 5-ml HisTrap nickel column (GE

797 Healthcare) and further polished using a Superdex 75 HiLoad 16/60 gel filtration column (GE

798 Healthcare).

799

800 *Bio-Layer Interferometry*

801   BLI experiments were run on an Octet Red 96e machine (Fortebio). To measure the binding

802   affinity of ACE2 with P.1 RBD and affinities of monoclonal antibodies and ACE2 with native

803   RBD and, RBD K417N, RBD K417T, RBD E484K and RBD K417T E484K N501Y, eachP.1

804   RBD, each RBD was immobilized onto an AR2G biosensor (Fortebio). Monoclonal antibodies

805   (Dejnirattisai et al., 2021) were used as analytes or serial dilutions of ACE2 were used as

806   analytes. All experiments were run at 30 °C. Data were recorded using software Data

807   Acquisition 11.1 (Fortebio) and Data Analysis HT 11.1 (Fortebio) with a 1:1 fitting model used

808   for the analysis.

809

810   *Antibody production*

811   AstraZeneca and Regeneron antibodies were provided by AstraZeneca, Vir, Lilly and Adagio

812   antibodies were provided by Adagio. For the chimeric antibodies heavy and light chains of the

813   indicated antibodies were transiently transfected into 293Y cells and antibody purified purified

814   from supernatant on protein A.

815

816   *Crystallization*

817

818   ACE2 was mixed with P.1 RBD in a 1:1 molar ratio to a final concentration of 12.5 mg ml^{-1}.

819   EY6A Fab, 222 Fab and WT or mutant RBD were mixed in a 1:1:1 molar ratio to a final

820   concentration of 7.0 mg ml^{-1}. All samples were incubated at room temperature for 30 min.

821   Most crystallization experiments was set up with a Cartesian Robot in Crystalquick 96-well X

822   plates (Greiner Bio-One) using the nanoliter sitting-drop vapor-diffusion method, with 100 nl

823   of protein plus 100 nl of reservoir in each drop, as previously described (Water et al., 2003).

824   Crystallization of B.1.1.7 RBD/EY6A/222 complex was set up by hand pipetting, with 500 nl

825   of protein plus 500 nl of reservoir in each drop. Good crystals of EY6A Fab and 222 Fab

826   complexed with WT, K417T, K417N, B.1.1.7, B.1.351 or P.1 RBD were all obtained from

827   Hampton Research PEGRx 2 screen, condition 35, containing 0.15 M Lithium sulfate, 0.1 M

828   Citric acid pH 3.5, 18% w/v PEG 6,000. Crystals of P.1 RBD/ACE2 complex were formed in

829   Hampton Research PEGRx 1 screen, condition 38, containing 0.1 M Imidazole pH 7.0 and

830   20% w/v Polyethylene glycol 6,000.

831

832   *X-ray data collection, structure determination and refinement*

833   Crystals of ternary complexes of WT and mutant RBD/EY6A and 222 Fabs and the P.1.

834   RBD/ACE2 were mounted in loops and dipped in solution containing 25% glycerol and 75%

835   mother liquor for a second before being frozen in liquid nitrogen prior to data collection.

836   Diffraction data were collected at 100 K at beamline I03 of Diamond Light Source, UK. All

837   data (except some of the WT RBD-EY6A-222 Fab complex images) were collected as part of

838   an automated queue system allowing unattended automated data collection

839   (https://www.diamond.ac.uk/Instruments/Mx/I03/I03-Manual/Unattended-Data-

840   Collections.html). Diffraction images of 0.1° rotation were recorded on an Eiger2 XE 16M

841   detector (exposure time of either 0.004 or 0.006 s per image, beam size 80×20 μm, 100% beam

842   transmission and wavelength of 0.9763 Å). Data were indexed, integrated and scaled with the

843   automated data processing program Xia2-dials (Winter, 2010;Winter *et al.*, 2018). A data set

844   of 1080° was collected from 3 positions of a frozen crystal for the WT RBD-EY6A-222 Fab

845   complex. 720° of data was collected for each of the B.1.1.7, P.1 and B.1.351 mutant

846   RBD/EY6A and 222 Fab complexes (each from 2 crystals), and 360° for each of the K417N

847   and K417T RBD with EY6A and 222 Fabs, and ACE2 complexes was collected from a single

848   crystal.

849

850   Structures of WT RBD-EY6A-222 and the P.1 RBD-ACE2 complexes were determined by

851   molecular replacement with PHASER (McCoy et al., 2007) using search models of SARS-

852   CoV-2 RBD-EY6A-H4 (PDB ID 6ZCZ) (Zhou et al., 2020) and RBD-158 (PDB ID, 7BEK)

853   (Dejnirattisai et al., 2021) complexes, and a RBD and ACE2 complex (PDB ID, 6LZG (Wang

854   et al., 2020)), respectively. Model rebuilding with COOT (Emsley and Cowtan, 2004) and

855   refinement with PHENIX (Liebschner et al., 2019) were done for all the structures. The ChCl

856   domains of EY6A are flexible and have poor electron density. Data collection and structure

857   refinement statistics are given in **Table S1**. Structural comparisons used SHP (Stuart et al.,

858   1979), residues forming the RBD/Fab interface were identified with PISA (Krissinel and

859   Henrick, 2007) and figures were prepared with PyMOL (The PyMOL Molecular Graphics

860   System, Version 1.2r3pre, Schrödinger, LLC).

861
862   *Quantification and statistical analysis*

863   Statistical analyses are reported in the results and figure legends. Neutralization was measured

864   by FRNT. The percentage of focus reduction was calculated and IC_{50} was determined using

865   the probit program from the SPSS package. The Wilcoxon matched-pairs signed rank test was

866   used for the analysis and two-tailed P values were calculated and geometric mean values. BLI

867   data were analysed using Data Analysis HT 11.1 (Fortebio) with a 1:1 fitting model.
