Abstract

The intracellular endosymbiotic proteobacteria *Wolbachia* have evolved across the phyla nematoda and arthropoda. In *Wolbachia* phylogeny, supergroup F is the only clade with members from both arthropod and filarial nematode hosts and therefore can provide unique insights into their evolution and biology. In this study, 4 new supergroup F *Wolbachia* genomes have been assembled using a metagenomic assembly and binning approach, *w*Moz and *w*Mpe from the human filarial parasites *Mansonella ozzardi* and *Mansonella perstans*, and *w*Ocae and *w*MoviF from the blue mason bee *Osmia caerulescens* and the sheep ked *Melophagus ovinus* respectively. A comprehensive phylogenomic analysis revealed two independent origins of filarial *Wolbachia* in supergroup F from ancestral arthropod hosts. The analysis also reveals that the switch from arthropod to filarial host is accompanied by a convergent pseudogenization and loss of the bacterioferritin gene, a phenomenon found to be shared by all filarial *Wolbachia*, even those outside supergroup F. These observations indicate that differences in heme metabolism might be a key feature distinguishing filarial and arthropod *Wolbachia*. The new genomes provide a valuable resource for further studies on symbiosis, evolution, and the discovery of new antibiotics to treat mansonellosis.

Key words

Wolbachia, Filaria, Evolution, Bacterioferritin, Heme, Phylogenomics

Significance statement

Wolbachia are bacterial endosymbionts of medically important parasitic filarial nematodes and arthropods. The evolutionary history and biological roles of *Wolbachia* in these different hosts

are not well understood. The supergroup F in *Wolbachia* phylogeny harbors members from both

filarial and arthropod hosts, providing an unparalleled opportunity for genomic comparisons to

uncover distinguishing characteristics. This study provides new genomes from filarial and

arthropod *Wolbachia*. Their phylogenomic analysis reveals multiple, independent transfers of

Wolbachia from arthropod to filariae. Remarkably, these transfers were associated with a

convergent loss of the bacterioferritin gene, a key regulator of heme metabolism. Heme

supplementation is considered a critical component of *Wolbachia* - filaria symbiosis. We

demonstrate bacterioferritin loss is a novel feature exclusive to filarial *Wolbachia*.

Introduction

Wolbachia are gram-negative α-proteobacteria of the order *Rickettsiales*, present as intracellular

symbionts in many species of parasitic filarial nematodes and arthropods (Werren et al. 2008).

While the *Wolbachia* associations in arthropods range from reproductive parasites to nutritional

mutualists (Werren et al. 2008; Zug & Hammerstein 2015), in filarial nematodes, *Wolbachia* is

an obligate mutualist (Taylor et al. 2005) and essential for worm development, fecundity and

survival (Taylor et al. 2005; Pfarr & Hoerauf 2006). *w*Mpe and *w*Moz are endosymbionts of

Mansonella perstans and *Mansonella ozzardi*, respectively, the human filarial parasites

responsible for mansonellosis. Mansonellosis is the most prevalent of all human filariases, yet

the least studied and most neglected (Downes & Jacobsen 2010; Simonsen et al. 2011; Lima et

al. 2016; Mediannikov & Ranque 2018; Ta-Tang et al. 2018; Sandri et al. 2021; Bélard &

Gehringer 2021). *M. perstans* is considered to be the most common filaria in West and Central

Africa (Simonsen et al. 2011; Ta-Tang et al. 2018), and is also found in the Amazon rainforest

and the Caribbean coast of South America (Ta-Tang et al. 2018; Tavares da Silva et al. 2017). *M.*

ozzardi infections have been reported from many countries in South and Central America,

including some Caribbean Islands (Lima et al. 2016; Ta-Tang et al. 2018; Raccurt 2018;

Calvopina et al. 2019). Co-infections of *M. perstans* and *M. ozzardi* are also known to exist in

South America (Kozek et al. 1983; Crainey et al. 2020), complicating treatment as the two

species respond differently to the commonly used anti-filarial drugs (Ta-Tang et al. 2018).

Antibiotics targeting *Wolbachia* have been successful in treating human filarial diseases such as

onchocerciasis and lymphatic filariasis (Pfarr & Hoerauf 2006; Langworthy et al. 2000;

Bazzocchi et al. 2008; Clare et al. 2019; Taylor et al. 2019; Hübner et al. 2019; Hong et al. 2019,

10). Doxycycline has been shown to clear *M. perstans* microfilariae (Ta-Tang et al. 2018; Keiser

et al. 2008; Coulibaly et al. 2009) and may have some efficacy against *M. ozzardi*, as well as

dual infections with *M. ozzardi* and *M. perstans* (Crainey et al. 2020), however, no such clinical

trials have been reported.

The *Wolbachia* present in the filarial nematodes of the genus *Mansonella* have a unique

phylogenetic position compared to *Wolbachia* present in other human filarial parasites. The latest

phylogenetic classification, based on Multi-Locus Sequence Typing (MLST), assigns *Wolbachia*

to various monophyletic supergroups (Lefoulon et al. 2016; Lefoulon, Clark, Guerrero, et al.

2020; Lefoulon, Clark, Borveto, et al. 2020). Supergroups A, B, E, H and S are comprised

entirely of arthropod *Wolbachia*, while supergroups C, D and J consist of filarial *Wolbachia*

exclusively. Interestingly, the *Wolbachia* from *Mansonella* are classified under supergroup F, the

only supergroup to have *Wolbachia* members from nematode as well as arthropod hosts. There is

considerable interest in studying these *Wolbachia* to better understand the evolution and biology

of arthropod and filarial *Wolbachia (*Lefoulon et al. 2016; Lefoulon, Clark, Guerrero, et al. 2020;

Nikoh et al. 2014; Hosokawa et al. 2010).

Genomic information provides a fundamental resource for these investigations, yet only

two genomes from supergroup F are currently available in public databases, namely the genomes

of *Wolbachia w*Cle from the bedbug *Cimex lectularius* (Nikoh et al. 2014), and *w*Mhie, from

Madathamugadia hiepei, a filarial parasite of geckos (Lefoulon, Clark, Guerrero, et al. 2020). In

the current study, the genomes of supergroup F *Wolbachia*, *w*Moz and *w*Mpe from human filarial

parasites *M. ozzardi* and *M. perstans* respectively, are assembled and analyzed. The genomes of

arthropod-associated supergroup F *Wolbachia*, *w*Ocae and *w*MoviF, from the mason bee, *Osmia*

caerulescens, and sheep ked, *Melophagus ovinus* are also reported. Results from genome-wide

analyses of synteny, phage-derived gene content, cytoplasmic incompatibility genes and

metabolic pathways of these genomes are described. In addition, comprehensive phylogenomic

analyses of these 4 new genomes and all the available *Wolbachia* genomes were performed to

generate comprehensive and robust phylogenetic trees, and confirmed the position of the new

genomes within supergroup F. These analyses revealed at least two independent origins of

filarial-*Wolbachia* association within supergroup F, most likely from ancestral arthropod-

Wolbachia systems, with an accompanying loss of the bacterioferritin gene. The loss of

bacterioferritin was discovered to be a feature common to all filarial *Wolbachia*.

Results

Genomes of *w*Moz and *w*Mpe, supergroup F *Wolbachia* from human filarial parasites *M. ozzardi* and *M. perstans*

A metagenomic assembly and binning pipeline suitable for complex clinical samples was utilized to analyze sequencing data from four *Mansonella* isolates. The binning of assembled metagenome scaffolds using BlobTools identified distinct clusters of scaffolds ("blobs") corresponding to the *Wolbachia* genome, distinguishable from blobs corresponding to the genomes of the worm hosts and associated microbiota.

For the *M. ozzardi* isolate Moz1 from Brazil, only fragments of *Wolbachia* genome at low coverage were obtained and were not analyzed further (Supplementary Figure S1a). The BlobTools analysis of *M. ozzardi* isolate Moz2 from Venezuela (Supplementary Figure S1b) yielded a draft *w*Moz assembly of 1,073,310 bp in size comprised of 93 scaffolds. The N50 size of this assembly is 17.225 kb and the largest scaffold is 37.481 kb in length (Table 1). Of the two *M. perstans* isolates Mpe1 and Mpe2 from Cameroon, only Mpe1 yielded a *Wolbachia* assembly (Supplementary Figure S2). The *w*Mpe assembly is comprised of 1,058,123 bp in 170 scaffolds, with a N50 size of 10.041 kb and the largest scaffold 28.485 kb in length (Table 1).

Whole genome alignment of *w*Moz and *w*Mpe demonstrated high sequence similarity and co-linearity of these independently assembled and closely related *Wolbachia* (Figure 1). A comparison was also made to the most closely related and the only complete genome available in the Clade F supergroup, namely *w*Cle, where high sequence synteny and co-linearity were also observed (Supplementary Figure S3).

Gene prediction using the NCBI PGAP pipeline identified 888 protein coding genes in

*w*Moz and 864 protein coding genes in *w*Mpe. A BUSCO analysis (v5.1.3) was performed on

these proteins to check for presence of the 219 genes conserved across most proteobacteria

("proteobacteria_odb10" database in BUSCO). The BUSCO scores of *w*Moz and *w*Mpe were

77.6% and 74.4% respectively (Table 1). These scores are typical for *Wolbachia,* even with

complete genomes. For example, the BUSCO scores for *Wolbachia w*Ov from the human filarial

parasite *Onchocerca volvulus*, *w*Oo from the bovine parasite *Onchocerca ochengi*, and *w*Bm

from the human filarial parasite *Brugia malayi* are 76.7%, 75.8%, and 79.5% respectively

(Supplementary Figure S4). Within supergroup F, the BUSCO score for filarial *Wolbachia*

*w*Mhie is 79%, and it is 81.7% for the arthropod *Wolbachia w*Cle.

Different isolates of *Mansonella* harbor varying levels of *Wolbachia*

The metagenomic assembly and binning approach enabled the determination of relative

amounts of *Wolbachia* in different isolates by comparing read coverages of the *Mansonella-* and

Wolbachia-specific scaffolds in the metagenomic assemblies (Table 2). In the *M. ozzardi* sample

Moz2, the median coverage of scaffolds classified as *Mansonella* was 360X, while that of the

Wolbachia scaffolds was 13X. Assuming 1000 nematode cells per microfilaria (Basyoni & Rizk

2016), each parasite is estimated to harbor 37 *Wolbachia* cells. For the other *M. ozzardi* isolate

Moz1, the median coverage for nematode scaffolds was 57X and the corresponding *Wolbachia*

coverage was only 3X. Therefore, titer calculations were not performed for the Moz1 isolate as

they would not be robust at such low coverage and incomplete assembly. For the *M. perstans*

sample (Mpe1), the median coverage of nematode scaffolds and *Wolbachia* scaffolds were

1,032X and 30X respectively, yielding an estimated titer of 30 *Wolbachia* per microfilaria. In the

other *M. perstans* isolate Mpe2, even though the median coverage for nematode scaffolds is

relatively high at 633X, only a very small portion of the *Wolbachia* genome, 15kb in 12 scaffolds

(less than 2% of 1.073 Mb *w*Mpe1 genome) with a median coverage of 7X could be obtained

during the metagenomic assembly, indicating a very low titer of *Wolbachia* in this isolate. The

low titer was also confirmed using a complementary analysis, namely mapping the Mpe2 reads

against the *w*Mpe1 assembly. In this analysis, the median depth of coverage obtained was only

9X, while the breadth of coverage (number of bases covered at 1X depth of coverage) was

observed to be 83 kb only, just 8% of the *w*Mpe1 genome. Since both isolates were collected in

Cameroon, these observations point to variation in *Wolbachia* titers within the same species in a

geographical area and could explain the conflicting reports of PCR-based detection of *Wolbachia*

in *M. perstans* (Sandri et al. 2021; Keiser et al. 2008; Coulibaly et al. 2009; Debrah et al. 2019;

Grobusch et al. 2003; Gehringer et al. 2014).

157   Genomes of *w*Ocae and *w*MoviF, supergroup F *Wolbachia* from the

158   arthropods *O. caerulescens* and *M. ovinus*

For the *Wolbachia w*Ocae from the mason bee *O. caerulescens*, metagenomic assembly

and binning was performed on Illumina sequencing reads available from a previous study (Gerth

et al. 2014). A BlobTools analysis of the assembled scaffolds identified a distinct cluster of 186

Wolbachia scaffolds (Supplementary Figure S5) with a total size of 1.2 Mb. The NCBI-PGAP

pipeline identified 899 protein coding genes, which had a BUSCO score of 79% (Table 1).

During the preparation of this manuscript, a metagenomic assembly WOLB0012 of *Wolbachia*

from the same raw data was published (Scholz et al. 2020), but only the un-annotated nucleotide

sequence is available in NCBI database. A BlobPlot analysis of this assembly indicated the

presence of arthropod contigs (Supplementary Figure S6). Therefore, instead of the WOLB0012

assembly, the carefully curated and annotated version of the *w*Ocae assembly described in this

manuscript was used for all subsequent analyses.

The *Wolbachia* genome from the sheep ked *Melophagus ovinus* was obtained from

analysis of publicly available reads. A first round of metagenomic assembly and BlobTools

analysis revealed a complex mixture of multiple *Wolbachia* as well as other proteobacterial

endosymbionts (Supplementary Figure S7). The total size of the 693 *Wolbachia* scaffolds

identified in this analysis was 1.6 Mb, substantially larger than any *Wolbachia* genomes known

so far. In addition, these scaffolds were spread over an unusually wide coverage range, over two

orders of magnitude. A manual inspection of the blastn hits of this assembly revealed that some

scaffolds had better hits against the genome of supergroup F *Wolbachia w*Cle, while others were

more similar to the supergroup A *Wolbachia w*Mel or supergroup B *Wolbachia w*AlbB.

Together, these observations point to multiple *Wolbachia* genomes in this sample. This

complexity necessitated an iterative mapping and assembly approach utilizing only the reads that

mapped to *Wolbachia* genomes, which produced 572 *Wolbachia* scaffolds with a total size 1.48

Mb (Supplementary Figure S8a). To identify the correct supergroup for each scaffold, its

sequence similarity and query coverage in comparison to the *w*Cle, *w*Mel or *w*AlbB genomes

were analyzed. The median percentage identity as well as query-coverage scores was observed to

be the highest against the *w*Cle genome, followed by the *w*Mel genomes, and was much lower

when compared to the *w*AlbB genome (Supplementary Figure S8b, 8c). Therefore, to isolate the

supergroup F scaffolds, alignments of each scaffold to *w*Cle genome was compared to its

alignments against the *w*Mel genome. Among the 572 scaffolds, 40 scaffolds had a nucmer hit

only to the *w*Cle genome and were therefore included in the supergroup F bin, 214 scaffolds had

a hit only to the *w*Mel genome (Supplementary Figure S8d) and were included in the supergroup

A bin, while 84 scaffolds that did not have a hit in either *w*Cle of *w*Mel genome were found to be

more similar to other *Wolbachia* from supergroups A or B. For the 234 scaffolds which had a

nucmer hit to both *w*Cle and *w*Mel genomes, an affiliation score, calculated as the difference

between its percentage identity to the *w*Cle genome and its percentage identity to the *w*Mel

genome, was analyzed. This score showed a clear bimodal distribution, with a range from -15 to

13 (Supplementary Figure S8e) confirming the presence of two *Wolbachia* from different

supergroups in the host *M. ovinus*. The scaffolds which had an affiliation score greater than zero

were assigned to the supergroup F. These 156 scaffolds also showed a read-coverage distribution

similar to the 40 scaffolds that had exclusive hits to the *w*Cle genome (Supplementary Figure

S8f), confirming their classification into supergroup F. The final supergroup F bin comprised of

196 scaffolds with a total size of 1.01 Mb was designated as the genome for *Wolbachia w*MoviF,

where the suffix F denotes the supergroup. NCBI-PGAP annotations identified 928 protein

coding genes, which had a BUSCO score of 81.3% (Table 1) and no duplicated core genes

(Supplementary Figure S4). The metagenomic bin for the putative supergroup A *Wolbachia* was

highly fragmented (301 scaffolds, median length = 823 bp, total size = 0.387 Mb), and was not

analyzed further. Recently, a metagenomic assembly of *Wolbachia* (GenBank accession

WOLB1015), based on the same raw reads became available (Scholz et al. 2020). However,

multiple analyses demonstrate that this assembly is a mixture of two different *Wolbachia*. First,

the protein coding genes in WOLB1015 were predicted using PROKKA, and their BUSCO score

was calculated. This analysis revealed duplications of 17% of single copy orthologs conserved

across *Wolbachia*, an unusually high rate in contrast to 0% duplications that are observed in

almost all other *Wolbachia* (Supplementary Figure S4). Second, a BlobPlot analysis of

WOLB1015 showed the *Wolbachia* contigs spread over an unusually wide coverage range from

1X to 1000X, consistent with the presence of multiple *Wolbachia* in this assembly

(Supplementary Figure S9). The WOLB1015 assembly had also failed to pass the QC criteria in

the original study (Scholz et al. 2020). Therefore, instead of the mixed WOLB1015 assembly,

the manually curated assembly of supergroup F *Wolbachia* *w*MoviF generated in this manuscript

was used for all downstream analyses.

Genome sequence comparisons between various *Wolbachia*

Analysis of whole genome alignments of the 4 newly assembled genomes to the complete

*w*Cle genome showed that most of the regions absent from *w*Moz, *w*Mpe, *w*Ocae or *w*Mhie

assemblies corresponded to regions containing IS element transposons in the *w*Cle genome

(Figure 2). This indicates that most of the protein coding regions have been recovered in these

draft genome assemblies, and the missing regions largely correspond to the IS elements, which

due to their repetitive nature present a technical challenge to assemble using only short-read data

(Sinha et al. 2019; Lefoulon et al. 2019).

Comparisons of sequence similarity between all supergroup F *Wolbachia* genomes, and

representatives from other supergroups including those from filarial nematodes, a plant parasitic

nematode, and arthropod hosts (Supplementary Table 1) were performed using genome-wide

average nucleotide identity (gANI, Supplementary Figure S10a) and digital DNA–DNA

hybridization (dDDH) scores (Supplementary Figure S10b-d). The dDDH scores provide more

sensitivity when comparing closely related species (Meier-Kolthoff et al. 2013). The

*w*Mpe:*w*Moz pair was found to have a dDDH score of 71.7% (Supplementary Figure S10b). For

comparison, the dDDH scores for other closely related sympatric *Wolbachia* are: 96.1 % for

*w*Oo:*w*Ov pair from *Onchocerca spp.*, and 93.3 % for *w*Bm:*w*Bpa pair from *Brugia spp.*

(Supplementary Figure S10c,d). These scores suggest *w*Mpe and *w*Moz have diverged

substantially from each other as compared to the *w*Oo:*w*Ov or *w*Bm:*w*Bpa pairs, most likely due

to them having split from their common ancestor before the *w*Bm:*w*Bpa or *w*Oo:*w*Ov split.

Orthology analysis, gene function and pathway annotations

Protein-coding gene sequences from NCBI-PGAP annotations were obtained for all 123

Wolbachia genomes available in GenBank (Supplementary Table 1). For orthology analysis,

protein-coding genes from the 4 new genomes, in addition to 77 genomes selected to represent

all supergroups, were used (see column H, Supplementary Table 1). The OrthoFinder analysis of

a total 82,406 proteins encoded by these 81 genomes identified 1,751 orthogroups, 99 of which

represent Single Copy Orthologs (SCOs) conserved across all the analyzed *Wolbachia*

(Supplementary Table 2). For the 4 new supergroup F *Wolbachia*, at least 96.9% of all predicted

proteins could be assigned to an orthogroup (Supplementary Table 2).

Functional annotations of the proteins encoded by the *w*Moz, *w*Mpe, *w*MoviF and *w*Ocae

genomes were obtained using the eggNOG database (Supplementary Table 3). Additionally,

biosynthetic pathway annotations for the *w*Cle genome were obtained from the KEGG database,

and corresponding orthologs were identified in the *w*Moz, *w*Mpe, *w*MoviF, *w*Ocae, and *w*Mhie

proteomes. Genes encoding members of various metabolic pathways characteristic of *Wolbachia*

proteomes, namely the heme pathway, purine and pyrimidine biosynthesis pathways, riboflavin

metabolism, and Type IV secretion systems, were found to be mostly present in *w*Moz and

*w*Mpe (Supplementary Table 4). Ribosomal protein subunits, a common target for anti-

Wolbachia drugs such as doxycycline, as well as candidate drug targets such as pyruvate

phosphate dikinase, PPDK (Raverdy et al. 2008), were also present in both *w*Moz and *w*Mpe.

Biotin biosynthesis genes are absent from all supergroup F *Wolbachia* except *w*Cle

The bedbug *Wolbachia w*Cle genome harbors an operon encoding the enzymes involved

in biosynthesis of biotin, which has been acquired via LGT from another *Rickettsia* ⸌Nikoh et al.

2014). The biotin produced by *w*Cle supports a nutritional mutualism between the bedbug and its

Wolbachia ⸌Nikoh et al. 2014). To investigate whether this feature is common to other

supergroup F *Wolbachia*, a search for the corresponding orthologs was performed. No orthologs

of any of the genes involved in the biotin biosynthesis pathway (genes *bioA*, *bioD*, *bioC*, *bioH*,

bioF and *bioB*) could be found in *w*Moz, *w*Mpe, *w*MoviF or *w*Ocae proteomes. Additionally,

when the sequencing reads from these 4 supergroup F *Wolbachia* were mapped against the *w*Cle

genome, no alignments could be found within the region harboring the biotin operon, even

though alignments could be obtained in the neighboring regions flanking the biotin operon

(Supplementary Figure S11). The absence of biotin pathway genes is unlikely to be due to the

incomplete nature of the draft assemblies. Given the high BUSCO score (at least 79%) of the

assemblies, if the biotin pathway was genuinely present in the genomes, at least fragments of a

few of the 6 genes in the biotin pathway would have been detected. In contrast, the 7 genes for

biosynthesis of riboflavin, another vitamin pathway important for the host-symbiont relationship

(Li & Carlow 2012; Moriyama et al. 2015; Ju et al. 2020) were present in *w*Cle as well as all

other supergroup F *Wolbachia* (Supplementary Table 4). Thus, biotin supplementation might be

unique to the bedbug and its *Wolbachia* association but is not the basis of mutualism between

other supergroup F *Wolbachia* and their corresponding filarial or arthropod hosts.

Prophage remnants and mobile genetic elements in supergroup F *Wolbachia* genomes

Many *Wolbachia* are naturally infected with lambda-like temperate phages, termed WO

phages, which can integrate into *Wolbachia* genomes as prophages (Bordenstein & Bordenstein

2022). The phage derived genes have been proposed to play important roles in generating genetic

diversity, chromosomal evolution and transfer of genes required for *Wolbachia* symbiosis

(Bordenstein & Bordenstein 2022). Phage-derived genes in all supergroup F *Wolbachia* were

identified via a comprehensive search for phage-derived orthogroups (Figure 3, Supplementary

Table 5) against a recently described database specific to *Wolbachia* phages (Bordenstein &

Bordenstein 2022). In the *w*Moz and *w*Mpe genomes, 37 and 33 phage-derived orthogroups were

found respectively, of which 32 were present in both *Wolbachia*. Among the gene members of

these phage-derived orthogroups, "hypothetical protein" was the most common annotation (n =

22) followed by "ankyrin domain protein" (n = 12). The filarial *Wolbachia* *w*Mhie had 32 phage-

associated orthogroups and shared 22 of these with *w*Moz and *w*Mpe. Neither *w*Moz, *w*Mpe, nor

*w*Mhie were found to possess any core components of phage structural modules, like the filarial

Wolbachia from other supergroups. Among arthropod *Wolbachia* of supergroup F, *w*Ocae had 29

phage structural genes, *w*MoviF had only 3 such genes, while *w*Cle had only one, suggesting

different dynamics of phage evolution in these *Wolbachia*.

Group II introns are common, phage-derived mobile elements (Bordenstein &

Bordenstein 2022) that can be found in high copy numbers in many *Wolbachia* genomes: for

example, 53 copies are found in the *w*AlbB genome (Sinha et al. 2019). Within the supergroup F

genomes, the *w*Ocae genome was found to encode only two copies of Group II introns. No such

genes could be detected in the *w*MoviF, *w*Moz or *w*Mpe genome assemblies. One pseudogene

was detected in both *w*Moz and *w*Mpe. No intact gene or pseudogene for these elements could be

found in the *w*Mhie or *w*Cle genomes, as reported earlier (Lefoulon, Clark, Guerrero, et al.

2020).

The *Wolbachia cifA-cifB* genes, which encode cytoplasmic incompatibility factors that

play a key role in the reproductive biology of their arthropod hosts, are also derived from phages

(Bordenstein & Bordenstein 2022; Lindsey et al. 2018). In supergroup F, no *cifA* or *cifB* genes

could be detected in the genomes of arthropod *Wolbachia w*Cle or *w*MoviF. In *w*Ocae, multiple

pseudogenes or fragments of *cifA* and *cifB* genes missing either the 5-prime or 3-prime ends

were identified (Supplementary Table 6). Since all the gene fragments were observed to be

located at the termini of the assembled scaffolds, they are most likely to be pseudogenes

disrupted by IS element insertions that tend to fragment the assemblies (Sinha et al. 2019). Thus,

*w*Ocae also seems to be devoid of any intact and functional *cifA-cifB* gene pair. No *cifA* or *cifB*

orthologs could be detected in filarial *Wolbachia w*Moz, *w*Mpe, or *w*Mhie.

Phylogenomic analysis encompassing all *Wolbachia* genomes

To determine the evolutionary relationships between the supergroup F *Wolbachia* and

other *Wolbachia*, as well as within supergroup F, comprehensive phylogenomic analyses were

performed. Using a total of 127 *Wolbachia* genomes, including all 123 annotated genomes

available from GenBank (Supplementary Table 1) as input for OrthoFinder, 46 Single Copy

Orthologs (SCOs) that are conserved across all available genomes were identified. The

corresponding phylogenetic tree based on their multiple sequence alignment spanning 8,394

amino acids was produced (Supplementary Figure S12). For a further refinement of the tree, all

incomplete or redundant genomes were excluded from analysis, except the genomes within

supergroup F (see column H, Supplementary Table 1). OrthoFinder analysis on these selected 81

genomes identified 99 SCOs (Supplementary Table 2). Maximum likelihood trees with a

partitioned model were built from the combined supermatrix of 62,160 nucleotides (Figure 4)

and 20,470 amino acids (Supplementary Figure S13). The 4 new genomes were robustly placed

within supergroup F in this analysis. In this tree, the *Wolbachia w*CfeJ from the cat flea *C. felis*,

which has not been assigned any supergroup yet, was found to be closest to supergroup F.

To further refine the phylogenetic relationships within the 6 supergroup F *Wolbachia*,

additional phylogenomic analyses were performed, using *w*CfeJ as an outgroup. OrthoFinder

analyses across these 7 genomes identified 525 SCOs enabling a higher resolution of supergroup

F phylogeny. The gene tree (Figure 5a) was built on a combined supermatrix of 469,845

nucleotides, and the corresponding protein tree (Supplementary Figure S14) was derived from a

combined supermatrix of 155,839 amino acids. Remarkably, the filarial *Wolbachia w*Moz and

*w*Mpe were placed in a clade different from the clade harboring *w*Mhie, the other filarial

Wolbachia in this supergroup. The filarial *Wolbachia w*Moz and *w*Mpe were most closely related

to the arthropod *Wolbachia w*MoviF and *w*Ocae, while the filarial *Wolbachia w*Mhie was more

closely related to the arthropod *Wolbachia w*Cle. Given the robust bootstrap support values for

the branches (Figure 5a), the most likely recent common ancestor for the *w*Moz, *w*Mpe lineage

would be an arthropod *Wolbachia* closer to *w*MoviF and *w*Ocae, while the *w*Mhie and *w*Cle

clade would have originated form a different arthropod *Wolbachia* ancestor. The clear separation

of the filarial *Wolbachia* into two separate, well-supported clades reveals that the filaria-

Wolbachia symbiosis has originated at least twice within this supergroup, from a different

ancestral arthropod *Wolbachia* in each case.

To expand the phylogenetic analysis of supergroup F *Wolbachia* beyond those with

whole genome sequences, gene sequences for 8 genes, including all MLST loci, as well as

groEL, *dnaA*, and 16S rRNA genes were collected from GenBank (Supplementary Table 7). The

corresponding sequences from *w*CfeJ were used as an outgroup. This tree (Figure 5b) also

robustly supports the separation of the *Mansonella Wolbachia* clade from the *w*Mhie clade.

Interestingly, the only other filarial *Wolbachia*, from the deer tick nematode *Cercopithifilaria*

japonica, is placed in a clade with *w*Mhie, with *w*Cle sharing a common ancestor with both these

filarial *Wolbachia*.

Convergent loss of bacterioferritin across all filarial *Wolbachia*

Genome reduction and gene loss is a recurrent theme in the evolution of endosymbionts

(Andersson & Kurland 1998), and the genomes of filarial *Wolbachia* are often found to be even

more reduced as compared to their arthropod counterparts. A study of the genes lost during this

evolutionary transition can therefore reveal genes that are either potentially dispensable or are

under negative selection for filaria-*Wolbachia* symbiosis. The analysis of orthology relationships

across 81 *Wolbachia* genomes (Supplementary Table 2) identified various orthogroups that are

absent in filarial *Wolbachia* but are present in arthropod *Wolbachia*. This approach uncovered a

striking loss of the bacterioferritin gene in filarial *Wolbachia* across all supergroups C, D, J and F

(Figure 4). Within supergroup F, at least two independent losses of the bacterioferritin gene were

observed, one in the *Mansonella Wolbachia* clade and the other in the *w*Mhie clade (Figure 5a).

Interestingly, pseudogene fragments of the *bfr* gene in various stages of degradation could be

found across filarial *Wolbachia* (Supplementary Figure S15a). In supergroups C and J, although

bfr pseudogenes were not found in the NCBI-PGAP annotations, blastx searches could identify

leftover fragments of bacterioferritin in the corresponding genomic region (Supplementary

Figure S15a). This genomic region was observed to be syntenic across all analyzed genomes

(Supplementary Figure S15a), confirming that the lack of the *bfr* gene is not due to assembly

artefacts. Although the bacterioferritin locus in the RefSeq annotations of *Wolbachia w*Bpa from

Brugia pahangi is annotated as an intact CDS instead of a pseudogene, a closer look at its

sequence and multiple sequence alignment with other bacterioferritin genes points to the loss of

the canonical start codon ATG, similar to the corresponding sequence in *w*Bm, as well as other

nucleotide insertions and deletions downstream (Supplementary Figure S15b), suggesting the

pseudogenization of this gene in *w*Bpa as well. The predicted peptide sequences corresponding

to these pseudogenes showed multiple premature stop codons and frameshifts (Supplementary

Figure S15c). Within supergroup F, all filarial *Wolbachia*, namely *w*Moz, *w*Mpe and *w*Mhie,

contain a pseudogenized bacterioferritin, even though their most recent ancestors from arthropod

Wolbachia have the corresponding gene intact. Since the *w*Moz:*w*Mpe pair is placed in a

separate clade from *w*Mhie (Figure 5), our results suggest that the *bfr* gene has been

pseudogenized independently in the two separate lineages.

Analysis of pseudogenes shared within the supergroup F *Wolbachia*

Intracellular bacterial symbionts, such as *Wolbachia*, are expected to accumulate

pseudogenes due to genetic drift over evolutionary timescales (Andersson & Kurland 1998).

However, the observation of two independent *bfr* pseudogenization events within supergroup F

Wolbachia suggests that additional factors, such as convergent evolution through negative

selection on certain genes could play a role in pseudogene formation. To explore the

contributions of these factors, pseudogenes shared between various supergroup F *Wolbachia*

were analyzed. This involved first determining the orthogroup corresponding to the ancestral

gene of each pseudogene (Supplementary Table 8). These "pseudogene-orthogroups" were then

compared to identify those unique or shared across different *Wolbachia* (Figure 6). For each

Wolbachia, the majority of its pseudogene-orthogroups were found to be unique to its genome,

whereas typically very few (n = 1 to 6) were shared between different *Wolbachia*, consistent with

the genetic drift model. An exception to this trend was the number shared between the filarial

*Wolbachia w*Moz, *w*Mpe and *w*Mhie (n = 15, Figure 6), which included the bacterioferritin

pseudogene described above. Since *w*Moz and *w*Mpe are placed in a clade separate from *w*Mhie,

these 15 pseudogene-orthogroups have most likely arisen from independent, convergent loss in

filarial *Wolbachia* across different lineages within supergroup F. The highest number of shared

pseudogene-orthogroups was observed in the *w*Moz:*w*Mpe pair (n = 39). The corresponding

pseudogenes might have arisen either through convergent evolution specific to *Wolbachia* within

Mansonella or were formed by genetic drift in the last common ancestor of *w*Moz and *w*Mpe, or

a combination of both factors.

Discussion

Wolbachia endosymbionts play critical roles in the biology of their arthropod and filarial

hosts, and there is great interest in understanding their diverse functions through genomic

approaches. The enigmatic supergroup F in *Wolbachia* phylogeny is the only supergroup

comprising symbionts of arthropod as well as filarial nematode hosts. In this report, 4 new

Wolbachia genomes from supergroup F are described, expanding the number of genomes from 2

to 6 in this under-represented supergroup. Two genomes are from *w*Moz and *w*Mpe,

endosymbionts of Mansonella *spp.*, important filarial parasites of humans, while the other 2

genomes are from *w*Ocae and *w*MoviF, endosymbionts of the mason bee *O. caerulescens* and the

sheep ked *M. ovinus* respectively.

Since *Wolbachia* are intracellular symbionts that cannot be cultured independently of

their hosts, it is not possible to obtain their DNA independent of the host and the associated

microbiome, presenting a challenge for accurate genome assembly. In the case of *w*Moz and

*w*Mpe, complex human clinical samples were used as the source material, containing a mixture

of DNA from human blood, the filarial parasite host, its intracellular symbiont *Wolbachia*, as

well as other constituents of the human microbiome. Similarly, for *w*Ocae and *w*MoviF genomes,

the publicly available sequencing data was derived from field-collected, wild isolates of their

arthropod hosts, and comprised DNA from the arthropod host, *Wolbachia*, as well as the

arthropod microbiome. Therefore, a metagenomic assembly and binning pipeline, customized to

each of the datasets, was necessary and played a critical role in obtaining high quality *Wolbachia*

genomes.

The BlobTools-based binning approach separates the assembled scaffolds based on their

GC content and relative read coverage, which also provides a means for an accurate

determination of *Wolbachia* titers via the measurement of relative copy numbers of genomes of

Wolbachia versus its host. This principle has been used in a metagenomic study for *Wolbachia*

titer calculations across multiple hosts (Scholz et al. 2020), and for highlighting sex-specific

differences in *Wolbachia* levels in *D. immitis* (Kumar et al. 2013). Given the longstanding

controversy around the detection of *Wolbachia* in *M. perstans* (Sandri et al. 2021; Keiser et al.

2008; Coulibaly et al. 2009; Debrah et al. 2019; Grobusch et al. 2003; Gehringer et al. 2014),

determination of *Wolbachia* titers in *Mansonella* is particularly important, and has implications

for antibiotic use as a treatment (Gehringer et al. 2014). In the current study, the titer in the

isolate Mpe1 was found to be 30 *Wolbachia* cells per microfilaria. In the isolate Mpe2, although

the presence of *Wolbachia* sequences could be detected, their depth and breadth of coverage was

too low for estimating the titer reliably. Importantly, this low *Wolbachia* coverage in Mpe2 is not

simply due to an overall low sequencing depth, as the corresponding genome for the host *M.*

perstans could be successfully assembled at a high coverage that was comparable to the isolate

Mpe1. As both Mpe1 and Mpe2 samples were collected in Cameroon, these observations

demonstrate that even within the same geographical region, *Wolbachia* levels can widely vary

between different isolates. For the *M. ozzardi* isolate Moz1, *Wolbachia* was detected but could

not be assembled due to overall low sequencing depth obtained for this sample. In isolate Moz2,

the titer was determined to be 37 *Wolbachia* cells per microfilaria, similar to Mpe1, and to levels

reported from a laboratory strain of *Brugia malayi* (McGarry et al. 2004). The presence of

Wolbachia in all *Mansonella* isolates described here, albeit at varying levels, and in another

human parasite *Mansonella* spp. "DEUX" (Sandri et al. 2021), together with the successful

clearance of *M. perstans* microfilariae with doxycycline (Coulibaly et al. 2009; Debrah et al.

2019), supports the use of antibiotics as a promising treatment for mansonellosis.

The *Wolbachia* from supergroup F present a unique opportunity to investigate the

evolutionary history of closely related arthropod and filarial *Wolbachia* since all other

supergroups are comprised exclusively of either arthropod or filaria associated *Wolbachia*. A

global phylogenomic analysis of 127 *Wolbachia* genomes, including all supergroup F genomes,

confirmed the placement of the 4 new genomes (*w*Moz, *w*Mpe, *w*MoviF, and *w*Ocae) in

supergroup F, and identifies *w*CfeJ as the most closely related and robust outgroup to this

supergroup. These phylogenomic analyses revealed two independent origins of filarial

Wolbachia within this supergroup. The *w*Moz and *w*Mpe pair shared a common ancestor with

the arthropod *Wolbachia* *w*Ocae and *w*MoviF, while *w*Mhie shared a different common ancestor

with the bed bug *Wolbachia* *w*Cle. While these evolutionary scenarios have previously been

proposed based on phylogenetic studies utilizing sequences from 2 to 7 gene loci (Lefoulon et al.

2012), the genome-wide phylogenies in this study are based on a supermatrix of 525 genes,

incorporating 2 new filarial and 2 new arthropod *Wolbachia* genomes, and include *w*CfeJ as the

most relevant outgroup, thereby providing the most comprehensive and robust evidence in

support of the independent origins. Another striking finding from these phylogenomic analyses is

the convergent pseudogenization of the bacterioferritin gene that is observed every time the

filarial-*Wolbachia* association evolves from the ancestral arthropod-*Wolbachia* association.

Within supergroup F, at least two independent losses of the bacterioferritin gene were observed,

one in the *w*Moz-*w*Mpe clade and the other in the *w*Mhie clade. Bacterioferritin is a critical

regulator of heme homeostasis in bacteria, serving as a store for heme that can be used during

heme deficiency, or sequestering excess heme to prevent toxicity (Carrondo 2003). In

arthropods, the presence of *Wolbachia* provides a fitness benefit by increasing fecundity during

conditions of iron deficiency (Brownlie et al. 2009), while during iron excess, *Wolbachia* protect

their insect hosts from iron induced toxicity by upregulating bacterioferritin (Kremer et al. 2009).

Heme is an essential nutrient required by filarial worms, but they lack a heme biosynthetic

pathway. Heme provisioning by *Wolbachia* has been proposed to play a key role in the obligate

host-symbiont relationship (Foster et al. 2005; Gill et al. 2014). The lack of bacterioferritin in

filarial *Wolbachia* suggests that *Wolbachia* cells can produce but no longer store heme

intracellularly, making it available for uptake by the host filaria, and in doing so, affording a

fitness advantage for the parasite. This difference in heme metabolism reveals an important

distinction between filarial *Wolbachia* as compared to arthropod *Wolbachia*. Although genome

reduction and gene loss, usually via genetic drift, is a recurrent theme in the evolution of

endosymbionts (Andersson & Kurland 1998), the loss of bacterioferritin gene across multiple

filarial *Wolbachia* is a unique example of convergent gene loss accompanying the adaptation to a

new ecological niche.

In summary, the comprehensive analysis of newly assembled supergroup F *Wolbachia*

genomes have provided the first genomic support for multiple origins of filaria and *Wolbachia*

symbiosis from ancestral arthropod hosts and uncovered an intriguing loss of bacterioferritin

from all filarial *Wolbachia*. Further studies of these genomes are expected to shed more light on

the evolution and nature of symbiosis, as well as the identification of new treatments for

mansonellosis.

Materials and Methods

Ethics statement

All research involving human subjects was approved by the appropriate committees and performed in accordance with all relevant guidelines and regulations. Informed consent was obtained from all participants or their legal guardians.

For *M. perstans*, ethical clearance was obtained from the National Institutional Review board, Yaoundé (REF: N° 2015/09/639/CE/CNERSH/SP) and administrative clearance from the Delegation of Public Health, South-West region of Cameroon (Re: R11/MINSANTE/SWR/ RDPH/PS/259/382). Approval for the study was granted by the "National Ethics Committee of Research for Human Health" in Cameroon. Special consideration was taken to minimize the health risks to which any participant in this study was exposed. The objectives of the study were explained to the consenting donor after which they signed an informed consent form. The participant's documents were assigned a code to protect the privacy of the study subject. At the end of the study, the donor received a cure of mebendazole (100 mg twice daily for 30 days).

For *M. ozzardi*, study protocols were approved by the Institutional Review Board of the Institute of Biomedical Sciences, University of São Paulo, Brazil (1133/CEP, 2013). Written informed consent was obtained from all patients, or their parents or guardians if participants were minors aged <18 years. Diagnosed infections were treated with a single dose of 0.2 mg/kg of ivermectin after blood sampling (Basano et al. 2018; Lima et al. 2018, 39).

Parasite materials and DNA extraction

M. ozzardi DNA was prepared from microfilariae collected from blood samples of

individuals who participated in a previous study in Brazil (Lima et al. 2018). A sample

containing a high microfilaria load was selected for genome sequencing and is denoted as Moz1

in the present study. A Venezuelan isolate of *M. ozzardi* microfilariae was generously donated by

Izaskun Petralanda in 1989 and is denoted as Moz2 in this study. Genomic DNA was prepared

from Moz2 microfilariae by Proteinase K digestion followed by phenol/chloroform extraction

and ethanol precipitation as well as drop dialysis

(https://www.neb.com/protocols/2013/09/16/drop-dialysis) then stored at -20°C. Two

independent isolates of *M. perstans* microfilariae, denoted as Mpe1 and Mpe2 in this study, were

collected on nylon filters from blood samples from Cameroon (Poole et al. 2019). Mpe1 DNA

was extracted using a Genomic DNA Tissue MicroPrep kit (Zymo Research, USA) as described

previously (Poole et al. 2019). DNA from Mpe2 was isolated as described above for Moz2. DNA

quantity was determined using a Qubit dsDNA HS Assay kit in conjunction with a Qubit 2.0

Fluorometer as directed by the manufacturer (Life Technologies, USA).

Illumina library construction and sequencing

Prior to library construction, the NEBNext Microbiome DNA enrichment kit (New

England Biolabs Inc., USA) was used to enrich parasite DNA and reduce human DNA

contamination (except for the Moz2 sample). The enrichment process is based on selective

binding and removal of CpG-methylated DNA islands present in human genome but absent from

nematode and *Wolbachia* genomes. The relative amounts of DNA from nematode and

Wolbachia therefore remains unaffected after the enrichment step. The preparation of Illumina

libraries from Mpe1 and Moz1 samples has been described as part of a previous study (Poole et

al. 2019), and a similar protocol was used for Mpe2 and Moz2, using the NEBNext Ultra II FS

DNA Library Prep Kit (New England Biolabs Inc., USA) as described by the manufacturer.

Following PCR amplification with different index primers to enable multiplexing, the libraries

were size selected using NEBNext Sample Purification Beads (NEB cat. # E7767) following

manufacturer's instructions. The approximate insert size and concentration of each library was

determined using a 2100 Bioanalyzer with a high sensitivity DNA chip (Agilent Technologies,

USA). Two Mpe2 libraries with insert sizes of approximately 500 and 800 bps and two Moz2

libraries with insert sizes of approximately 500 and 950 bps were constructed. Libraries were

diluted to 4 nM with 10 mM Tris, 0.1 mM EDTA pH 8 for sequencing. Due to the A:T rich

nature of filarial genomes, Phi X DNA was added to balance base pair composition, then

sequenced using the Illumina MiSeq and NextSeq500 platforms (paired end, 150 bps).

Metagenomic assembly and binning

Raw reads were processed using the BBTools package v38.51

(https://sourceforge.net/projects/bbmap/). Duplicate raw reads and bad tiles were removed using

the clumpify.sh and filterbytile.sh utilities. Adapter trimming as well as removal of phiX reads

and reads with 13-nt or longer stretches of the same nucleotide (poly-G, -C, -A or-T) were

performed using bbduk.sh. Human host reads were removed by mapping against the human

genome (grch38) using the bbmap.sh utility. The quality metrics of the processed reads at each

step were assessed using FastqC v0.11.9

(https://www.bioinformatics.babraham.ac.uk/projects/fastqc/).

Reads from different runs of the libraries prepared from the same genomic DNA sample

were combined and used as an input for the assembly of the metagenome using metaSpades

v3.14.0 (Nurk et al. 2017). Input reads were mapped back to the assembled scaffolds using

bowtie2 v.2.4.1 (Langmead & Salzberg 2012). Binning of metagenomic scaffolds into

metagenome assembled genomes of *Mansonella* and *Wolbachia* was performed using the

BlobTools v1.1.1 software (Laetsch & Blaxter 2017) and additional manual curation. The bins

annotated as "Proteobacteria" and "Nematoda" were analyzed further to retrieve sequences

genuinely originating from *Wolbachia*. A cluster of "Proteobacteria" scaffolds in the blobplots of

each of the metagenomes was analyzed using blastn against the *w*Cle genome to verify their

Wolbachia origin. These scaffolds were subsequently collected as respective *Wolbachia*

assemblies from each of the isolates. The combined size of scaffolds collected from the Moz1

isolate was only 120 kb, much smaller than a 1 Mb genome typically seen for *Wolbachia,* and so

were not analyzed further. Similarly, in the Mpe2 sample, only 12 scaffolds with a total size of

15 kb were identified as candidate *Wolbachia* sequences and were not analyzed further. The tight

clusters of "Proteobacteria" scaffolds in the blobplots of Moz2 and Mpe1 were classified as the

*w*Moz and *w*Mpe genome assemblies respectively. For the remaining clusters of metagenome

scaffolds that were also marked "Proteobacteria" by BlobTools but had a distinctly different

%GC as compared to the *Wolbachia* scaffolds, blastn searches against the NCBI-nt database

were performed to verify that they did not originate from the *Wolbachia* genome. All the

bioinformatics programs were run using the default parameters unless otherwise stated.

The genome sequence of *Wolbachia w*Ocae from the mason bee *Osmia caerulescens* was

assembled from Illumina reads available under NCBI SRA accession SRR1221705, originally

described in a previous study of arthropod *Wolbachia* (Gerth et al. 2014). The reads were

assembled into metagenomic scaffolds using metaSpades. A BlobTools analysis of the resulting

assembly was used to identify the cluster of *Wolbachia* scaffolds.

The genome sequence of *Wolbachia w*MoviF from the sheep ked *Melophagus ovinus* was

assembled from raw Illumina reads corresponding to the NCBI SRA accession number

ERR969522, which originated from a study of sheep ked endosymbionts (Nováková et al. 2015)

that were also used recently for *Wolbachia* genome mining (Scholz et al. 2020). In the first round

of assembly using all reads as input to metaSpades assembler, potential *Wolbachia* scaffolds

were identified using BlobTools. However, a preliminary blastn analysis of these scaffolds

indicated a contaminating genome from supergroup A or B *Wolbachia*, in addition to the

expected supergroup F *Wolbachia* in this sample. Due to the complicated nature of this dataset,

additional iterations of metagenomic assembly and binning were performed using only the reads

that mapped to a "bait" database containing all known *Wolbachia* genomes. The mapping of

reads to bait databases was performed using bowtie2 (v.2.4.1). The bait database was updated to

include the newly assembled sequences, and a new subset of reads was obtained by mapping to

this updated database. These reads were then used as input for another round of metagenomic

assembly. Candidate *Wolbachia* scaffolds were selected using BlobTools. Whole genome

alignments of the assembled scaffolds to three representative and complete reference genomes,

namely *w*Cle (supergroup F), *w*Mel (supergroup A), and *w*AlbB (supergroup B) were performed

using nucmer v4.0.0beta2 (Marçais et al. 2018, 4) with the parameter "mincluster" set to 100.

Genome annotation and comparative analysis

For both *w*Mpe and *w*Moz genomes, as well as the *w*Ocae and *w*MoviF genomes,

protein-coding genes, rRNA, tRNA, ncRNA genes and pseudogenes were identified using the

NCBI prokaryotic genome annotation pipeline (Tatusova et al. 2016). The completeness of the

protein-coding content of all 4 genomes was assessed using the BUSCO pipeline v5.1.3 using the

"proteobacteria_odb10" reference dataset (Simão et al. 2015). Syntenic blocks between various

pairs of genomes were analyzed and visualized using the JupiterPlot tool

(https://github.com/JustinChu/JupiterPlot) which uses minimap2 (v 2.17-r941) for whole-

genome alignments (Li 2018). The parameters used in Jupiter plots are maxGap = 100,000;

minBundleSize = 1,000; m_ref_contig_cutoff = 500; gScaff = 500. The parameter 'ng' was set to

100%, so that all the scaffolds from the two assemblies being compared are displayed in the

Jupiter plots. Whole-genome alignments of *w*Moz, *w*Mpe, *w*Ocae and *w*MoviF, as well as

*w*Mhie, against *w*Cle as the reference genome were performed using the nucmer utility in

MUMmer4 with default parameters. The resulting alignment blocks were visualized as

concentric Circos plots (Krzywinski et al. 2009) drawn using the R package circlize v0.4.10 (Gu

et al. 2014). For global sequence comparisons across multiple *Wolbachia* genomes, the average

nucleotide identity (ANI) scores were calculated using the OrthoANIu tool v1.2 (Yoon et al.

2017). The pairwise ANI scores were used for hierarchical clustering of different *Wolbachia,* and

a correlation plot was generated using R package corrplot v0.84

(https://github.com/taiyun/corrplot). For a more sensitive measure of sequence similarity and

divergence between closely related *Wolbachia*, digital DNA–DNA hybridization (dDDH) scores

(Meier-Kolthoff et al. 2013) were computed using the recommended "formula 2" at the

"Genome-to-Genome Distance Calculator" (GGDC) web-service

(https://ggdc.dsmz.de/ggdc.php). The orthologs of protein coding genes across multiple

Wolbachia genomes were inferred using OrthoFinder v2.4 (Emms & Kelly 2019).

Insertion sequence (IS) elements were identified via the ISsaga web server (Varani et al.

2011) and by parsing the annotations in GenBank format from NCBI-PGAP pipeline. Other

transposons and Group II introns were also inferred via parsing the GenBank files. Functional

annotation of protein-coding genes was carried out using the eggNOG-Mapper (Huerta-Cepas et

al. 2017) web server (http://eggnogdb.embl.de/#/app/emapper). The analysis of different

metabolic pathways was based on the annotations of *w*Cle and *w*Bm genomes available in the

KEGG database (Kanehisa et al. 2017).

Phylogenomic analysis

Phylogenomic analysis was carried out on three distinct sets of input genomes. The first

set comprised 127 genomes and included 123 annotated *Wolbachia* genomes available in the

NCBI GenBank database (Supplementary Table 1) as well as the 4 genomes reported in this

study. For a more robust and refined tree, a second set was used comprising 81 genomes selected

from the 127 genomes, excluding incomplete genomes (except those within supergroup F) as

well as redundant genomes e.g., multiple isolates of the same *Wolbachia* (Supplementary Table

1). The third set included only the genomes from supergroup F *Wolbachia*, and *w*CfeJ *Wolbachia*

from the cat flea *Ctenocephalides felis* as an outgroup.

For each input set, OrthoFinder was used to identify Single Copy Orthologs (SCOs)

conserved across all genomes within the set. Protein sequences corresponding to each orthogroup

were aligned using mafft v7.149b (Nakamura et al. 2018). The multiple sequence alignments

were trimmed using Gblocks v0.91b (Talavera & Castresana 2007). The trimmed blocks from

each conserved orthogroup were then concatenated into a supermatrix, and the length of each

alignment block was recorded in a nexus format partition file. The corresponding gene sequence

tree was generated by collecting the transcript sequences corresponding to the single copy

orthologs conserved across all input *Wolbachia*. The DNA sequences corresponding to each

conserved orthogroup were first aligned using mafft and then concatenated into a supermatrix

sequence, with the lengths of the alignment blocks recorded in a nexus format partition file.

Maximum likelihood trees were generated based on protein sequences as well as gene sequences,

using the corresponding concatenated supermatrix sequence and partition files (Chernomor et al.

2016) as inputs to iqtree v2.1.2 (Nguyen et al. 2015). Automatic selection of substitution models

was performed using ModelFinder (Kalyaanamoorthy et al. 2017) implementation in iqTree

(iqTree command line option '-m MFP'). Evaluation of branch supports was performed using the

iqTree implementations of (i) the SH-like approximate likelihood ratio test (Guindon et al.

2010), and (ii) ultrafast bootstrap (Hoang et al. 2018) with 1000 replicates each (iqTree

command-line options '-B 1000 -alrt 1000 -abayes -lbp 1000'). The consensus trees were

visualized using the iTOL webserver (Letunic & Bork 2021) and further annotated in Adobe

Illustrator.

For a phylogenetic analysis of all supergroup F *Wolbachia* based on a combined

supermatrix of multiple genes, the sequences for their MLST loci *ftsZ*, *fbpA*, *coxA*, *gatB*, *hcpA*

and other loci (*groEL*, *dnaA*, ftsZ and 16S rRNA) were obtained from their genome assemblies

and GenBank. The corresponding sequences from *w*CfeJ was used as outgroup. Only the

Wolbachia with sequences available for at least 3 of these 8 loci were included in this analysis.

The multiple sequence alignment of the combined supermatrix of sequences was performed

using MUSCLE (Edgar 2004). Phylogenetic tree with automatic model selection, standard

bootstrap calculations and single branch tests was generated using iqtree (command-line options

-b 1000 -alrt 1000 -abayes).

Gene loss and pseudogene analysis

OrthoFinder results, from the set of 81 genomes described above, were analyzed to

identify gene loss events across different *Wolbachia*, by cataloging orthogroups which had gene

members present in all arthropod *Wolbachia* but absent in filarial *Wolbachia*.

Pseudogenization of protein-coding genes is a major factor contributing to gene loss.

Pseudogenes common across different supergroup F *Wolbachia* were identified as follows. A

catalog of pseudogenes for each *Wolbachia* was first obtained from its NCBI-PGAP annotation.

Next, for each pseudogene, the GenBank accession for its most likely intact ancestral protein was

also obtained from the NCBI-PGAP annotations. For a phylogenetically consistent and robust

analysis, instead of comparing these protein accessions directly, the corresponding ancestral

orthogroup was retrieved from the results of OrthoFinder and these "pseudogene-orthogroups"

were compared across different *Wolbachia*. If the same orthogroup was found to be

pseudogenized in more than one *Wolbachia*, the corresponding pseudogenes were designated as

shared or common pseudogenes. The overlap between the ancestral pseudogene-orthogroups

across different *Wolbachia* was visualized using the R package UpsetR (Conway et al. 2017).

Pseudogenes derived from transposons and IS elements were excluded from this analysis.

Annotation of phage derived elements and cytoplasmic incompatibility factors

Phage-derived genes and pseudogenes were annotated following the latest taxonomic

classification scheme of *Wolbachia* phages (Bordenstein & Bordenstein 2022). The sequences of

Wolbachia phage genes and pseudogenes were obtained from the Phage-WO database available

at https://lab.vanderbilt.edu/bordenstein/phage-wo/database. Their best sequence matches in the

proteomes of the set of 81 *Wolbachia* genomes were first identified using blastp and blastx

searches. The orthogroups corresponding to these best hits were considered as phage-derived

orthogroups, and the corresponding orthologs in supergroup F *Wolbachia* were annotated as

phage-derived genes. Genes encoding IS-elements were excluded from this analysis to avoid

mismatches and overcounting arising from the repeated and fragmented nature of genes in these

families. Pseudogenes were annotated as phage-derived if their predicted ancestral proteins had

an ortholog in the phage WO database. For *cifA* and *cifB* gene annotations, reference gene

sequences were compiled from published data (Martinez et al. 2021) and used in blast searches

against the proteomes from the 81 *Wolbachia* genomes used in the phylogenomic analysis above,

and the corresponding orthogroups and orthologs within supergroup F *Wolbachia* were annotated

as *cifA* and *cifB*.

Acknowledgments

The authors thank Jeremy Foster and Sofia Roitman for helpful discussions and comments on the

manuscript, and Laurie Mazzola and Danielle Fuchs from the DNA sequencing core at New

England Biolabs. The work was inspired by Don Comb and funded by New England Biolabs.

Field research in Brazil was supported by the Fundação de Amparo à Pesquisa do Estado de São

Paulo (FAPESP), research grant to M.U.F. (2013/12723-7) and doctoral scholarship to N.F.L.

(2013/ 26928-0).

Author Contributions

721 N.F. L., M. U. F., F.F. F., S.W. collected the clinical samples. A.S., Z. L, C.B. P., L. E.

722 performed the sequencing experiments and bioinformatics analysis. A.S., Z. L, C.B. P., L.E.,

723 C.K.S.C. analyzed the data. A.S., Z. L, C.B. P., C.K.S.C wrote the initial manuscript. A.S., Z. L,

724 C.B. P., L.E., M. U. F., S.W., C.K.S.C and all authors contributed to the final manuscript.

735   # Not calculated due to the very low number or coverage of *Wolbachia* scaffolds

Figure Legends

Fig. 1. High sequence similarity and synteny between the *de novo* assembled *w*Moz and

***w*Mpe genomes**

The *Wolbachia* genomes assembled from two biologically and geographically distinct isolates

display a high level of synteny and inter-genome consistency. The genomes were aligned using

minimap2 and visualized using the JupiterPlot software. The *w*Moz scaffolds are displayed as

colored boxes in the left semi-circle, while the *w*Mpe scaffolds are shown as gray boxes in the

right semi-circle. The syntenic regions are marked by bands connecting scaffolds from one

assembly to the corresponding region in the other assembly. Regions of rearrangement are shown

as bands crisscrossing the horizontal bands of the syntenic regions.

Fig. 2. Gaps in the assembled *Wolbachia* genomes correspond mostly to IS elements.

Whole genome alignments of *w*Mpe (blue ring), *w*Moz (light-blue ring), *w*Ocae (green ring),

*w*MoviF (light green ring) and *w*Mhie (innermost gray ring) to the *w*Cle chromosome (outermost

black circle) are visualized as a circos plot. The white bars mark the locations of the IS elements

in the *w*Cle genome. The gaps in the alignments of various genomes to the *w*Cle genome overlap

extensively with IS elements in the *w*Cle genome.

Fig. 3. Numbers of phage-derived genes and their functional distributions in supergroup F

Wolbachia

Phage derived genes in each *Wolbachia* were categorized according to their predicted protein

function. Phage-derived genes which had annotations other than "Hypothetical protein" but

could not be classified as either "Core structural" or "Ankyrins" were included in the category

"Others". Only *w*Ocae has intact phage modules, while *w*MoviF and *w*Cle have only one and

two core structural phage genes respectively. Phage structural genes were absent from filarial

*Wolbachia w*Moz, *w*Mpe and *w*Mhie.

Fig. 4. Global phylogenomic analysis of all *Wolbachia* genomes

Phylogenomic tree based on gene sequences of 91 single copy orthologs (SCOs) conserved

across 81 *Wolbachia* representing all supergroups. Supergroups comprised of *Wolbachia*

exclusively from arthropod hosts are marked in blue, while the supergroups comprised

exclusively of filarial *Wolbachia* are marked in orange. The supergroup F, which has members

from both arthropod and filarial hosts, is marked in purple background. The red asterisks denote

the *Wolbachia* with a pseudogenized or absent bacterioferritin gene.

Fig. 5. Two independent origins of *Wolbachia*-filaria symbiosis within supergroup F

(a) The phylogenomic tree based on gene sequences of 525 SCOs conserved across all supergroup F *Wolbachia* indicates at least two independent origins of filaria-*Wolbachia* symbiosis, most likely from an arthropod-*Wolbachia* ancestor. The *w*Mpe/*w*Moz lineage has split from the clade containing *w*Ocae and *w*MoviF, while *w*Mhie shares a different common ancestor with the bed bug *Wolbachia w*Cle. The arthropod *Wolbachia w*CfeJ from the cat flea *C. felis* was used as the outgroup. The red asterisks denote the *Wolbachia* with a pseudogenized or absent bacterioferritin gene. The bootstrap values are shown along the respective branches. (b) Phylogenetic tree of supergroup F *Wolbachia* based on a supermatrix of 8 genes (*ftsZ*, *fbpA*, *coxA*, *gatB*, *hcpA*, *groEL*, *dnaA*, 16S rRNA), total sequence length 10,374 nucleotides, also supports at least two independent origins of filarial *Wolbachia*. All *Wolbachia* from *Mansonella* hosts, including *M. perforata* are placed in a clade adjacent to the clade harboring arthropod *Wolbachia w*Ocae and *w*MoviF, while the *Wolbachia w*Mhie and *w*Cjaponica from filarial hosts *M. hiepei* and *Cercopithifilaria japonica* are in a separate clade that is more closely related to the arthropod *Wolbachia w*Cle. Filarial *Wolbachia* are marked with orange font. Only the standard bootstrap values higher than 75 are shown.

Fig. 6. Pseudogenes shared between supergroup F *Wolbachia*

The orthogroups corresponding to the ancestral gene of each pseudogene were compared across different *Wolbachia*. Each *Wolbachia* harbors its unique set of pseudogenes, reflecting their origin as evolutionary accidents. The largest set of shared pseudogenes is observed between the closely related *w*Moz and *w*Mpe *Wolbachia* (n = 39, dark orange bar), suggesting either a shared common ancestor or convergent evolution within their respective *Mansonella* hosts. The next

793 largest shared set of pseudogenes is found among the *Wolbachia* *w*Moz, *w*Mpe, and *w*Mhie (n =

794 15, blue bar), which are phylogenetically in different clades, indicating that the corresponding

795 genes have undergone convergent loss of function across the three filarial *Wolbachia* in

796 supergroup F. Transposons such as IS elements were excluded from this analysis due to their

797 tendency to frequently convert into pseudogenes.

Data Availability Statement

Raw Illumina reads for the *M. perstans* isolate Mpe1 and the *M. ozzardi* isolate Moz2 have been

deposited in the NCBI SRA database under BioProject accession numbers PRJNA666672 and

PRJNA666671 respectively. The assembled genome and PGAP annotations for the *Wolbachia*

*w*Mpe and *w*Moz are available from the NCBI GenBank database with accession numbers

JACZHU000000000 and JADAKK000000000 respectively. The annotated genomes for *w*Ocae

and *w*MoviF are available as GenBank accessions JAHDJT000000000 and JAHRBA000000000

respectively, deposited under BioProject accessions PRJNA244005 and PRJNA739984

respectively.
