**Solar simulated ultraviolet radiation inactivates HCoV-NL63
and SARS-CoV-2 coronaviruses at environmentally relevant doses**

Keywords: Coronavirus; HCoV-NL63; SARS-CoV-2; Solar simulated ultraviolet radiation; Viral
inactivation

23 **ABSTRACT**

24 The germicidal properties of short wavelength ultraviolet C (UVC) light are well established and
25 used to inactivate many viruses and other microbes. However, much less is known about
26 germicidal effects of terrestrial solar UV light, confined exclusively to wavelengths in the UVA
27 and UVB regions. Here, we have explored the sensitivity of the human coronaviruses HCoV-
28 NL63 and SARS-CoV-2 to solar-simulated full spectrum ultraviolet light (sUV) delivered at
29 environmentally relevant doses. First, HCoV-NL63 coronavirus inactivation by sUV-exposure
30 was confirmed employing (i) viral plaque assays, (ii) RT-qPCR detection of viral genome
31 replication, and (iii) infection-induced stress response gene expression array analysis. Next, a
32 detailed dose-response relationship of SARS-CoV-2 coronavirus inactivation by sUV was
33 elucidated, suggesting a half maximal suppression of viral infectivity at low sUV doses. Likewise,
34 extended sUV exposure of SARS-CoV-2 blocked cellular infection as revealed by plaque assay
35 and stress response gene expression array analysis. Moreover, comparative (HCoV-NL63 versus
36 SARS-CoV-2) single gene expression analysis by RT-qPCR confirmed that sUV exposure blocks
37 coronavirus-induced redox, inflammatory, and proteotoxic stress responses. Based on our findings,
38 we estimate that solar ground level full spectrum UV light impairs coronavirus infectivity at
39 environmentally relevant doses. Given the urgency and global scale of the unfolding SARS-CoV-
40 2 pandemic, these prototype data suggest feasibility of solar UV-induced viral inactivation, an
41 observation deserving further molecular exploration in more relevant exposure models.

42

43 Abbreviations: MOI, multiplicity of infection; sUV, solar simulated ultraviolet light; UV,
44 ultraviolet.

45

46 **1. Introduction**

47 The germicidal properties of short wavelength ultraviolet C (UVC) light are well established
48 and widely used to inactivate many viruses and other microbes, and virucidal activity of solar UVC
49 targeting pathogenic coronaviruses has been explored in much detail before [1-3]. Given the
50 urgency and global scale of the unfolding SARS-CoV-2-caused COVID-19 pandemic, UV-
51 induced inactivation of coronaviruses including SARS-CoV-2 has reemerged as a matter of much
52 contemporary research interest [2-8]. Indeed, recently, rapid and complete inactivation of SARS-
53 CoV-2 by UVC has been substantiated experimentally, and virucidal UVC light sources (254 nm
54 emission) are used for surface disinfection and decontamination [5,8]. Moreover, far UVC (222
55 nm) has attracted considerable attention due to its potent virucidal activity [2]. However, much
56 less is known about germicidal (and coronavirus-directed) effects of terrestrial (ground level) solar
57 UV light, a matter of much interest given the airborne spread of coronaviruses including SARS-
58 CoV-2 [2,6]. UVC (< 290 nm) is not present in the solar spectrum reaching the Earth's surface,
59 and most of solar UV energy incident on the skin is from the UVA region (>95%; from 320–400
60 nm). Remarkably, the UVB (290–320 nm) proportion of total solar UV-flux received by skin can
61 be well below 2% depending on the solar angle, which determines the atmospheric light path length
62 and thereby the degree of ozone-filtering and preferential Rayleigh scattering of short wavelength
63 UV light [9].

64 Recently, the role of ground level (environmentally relevant) solar UV has been explored in the
65 context of SARS-CoV-2 disinfection, and a role of solar UVB in human coronavirus inactivation
66 has been substantiated based on atmospheric and geophysical simulations [2,6,10,11].
67 Specifically, inactivation times of SARS coronaviruses exposed to environmental photons with
68 wavelengths between 290-315 nm have been calculated using OMI (ozone monitoring instrument)

69 satellite data for the sunlit earth [10]. Moreover, recent research has demonstrated that simulated
70 sunlight rapidly inactivates SARS-CoV-2 on surfaces including human saliva when exposed to
71 simulated sunlight representative of the summer solstice at 40 °N latitude at sea level on a clear
72 day [10]. Also, indirect effects of solar UVB exposure in reducing COVID-19 deaths have been
73 substantiated, potentially mediated by UVB-driven cutaneous vitamin D synthesis, among other
74 factors [12-14]. In addition, a role of solar UVA photons in the inactivation of coronaviruses has
75 been proposed [7].

76 Given the complexity of virucidal activity as a function of spectral composition from ultraviolet
77 to infrared, a topic recently reviewed by various authors, a more detailed knowledge and direct
78 evidence of solar UV-induced coronavirus inactivation (achievable at ground level and
79 environmentally relevant doses) would offer improved options that inform decisions at the basic
80 research, clinical care, and public health levels [2,6,8]. Here, for the first time, we have explored
81 the sensitivity of the human coronaviruses HCoV-NL63 and SARS-CoV-2 to solar simulated
82 ultraviolet light (sUV). Our findings suggest that solar UV delivered at environmentally relevant
83 dose levels inactivates HCoV-NL63 and SARS-CoV-2 coronaviruses with pronounced blockade
84 of infectivity protecting mammalian host cells.

85

86 **2. Materials and Methods**

87 ***2.1. Chemicals***

88 All chemicals were purchased from Sigma Aldrich (St. Louis, MO, USA).

89

90 ***2.2. Mammalian cell culture, viral propagation, and target cell infection***

91 As established viral target cells infected by HCoV-NL63 and SARS-CoV-2, Calu-3 human
92 metastatic lung epithelial adenocarcinoma (HTB-55), Caco-2 human colorectal epithelial

93 adenocarcinoma (HTB-37) and Vero normal epithelial monkey kidney (CCL-81) cells (all from
94 ATCC, Manassas, VA, USA) were maintained according to published standard procedures [15-
95 18]. In brief, all cells (Calu-3, Caco-2 and Vero) were cultured in Eagle's Minimum Essential
96 Medium (MEM) medium (Corning, Manassas, VA) supplemented with 10% bovine calf serum
97 (BCS, HyClone™ Laboratories, Logan, UT). Coronavirus HCoV-NL63 (NR-470) and its
98 genomic RNA (NR-44105) were obtained from BEI Resources (NIAID, NIH). SARS-CoV-2
99 strain WA1 (NR-52281; BEI Resources) was propagated in Vero cells unless specified otherwise
100 [6]. For viral stocks, cells were infected at a multiplicity of infection (MOI) of 0.01 and cultured
101 for 48 h. At that point, cells were harvested, homogenized, subjected to a single freeze-thaw cycle,
102 and then combined with the culture supernatant followed by centrifugation (3000 rpm, 10 min).
103 The viral titers of the final supernatant (after serial dilution) was determined by plaque forming
104 assay. All work with SARS-CoV-2 was performed under BSL3 conditions in a facility with
105 negative pressure and PPE that included Tyvek suits and N95 masks for respiratory protection.

106

107 ***2.3. Viral irradiation with solar simulated UV light (sUV)***

108 A KW large area light source solar simulator, model 91293, from Oriel Corp. (Stratford, CT)
109 was used, equipped with a 1000W xenon arc lamp power supply, model 68920, and a VIS-IR band
110 pass blocking filter plus either an atmospheric attenuation filter (output 290–400 nm plus residual
111 650–800 nm for solar simulated light) [19,20]. For viral irradiation, viral stocks were diluted
112 >1:100 in PBS and irradiated in a sealed UV-transparent cuvette [BrandTech™ BRAND™ UV-
113 Cuvets, providing transparency from 230 to 900 nm, widely used for DNA, RNA and protein
114 analysis (BrandTech™ 759170, Fisher Scientific)]. The cuvette was inserted into a fully UV-
115 transparent scintillation counter vial (Wheaton '180' low-potassium glass, SigmaAldrich

116 Z253081). The UV output was quantified using a dosimeter from International Light Inc.
117 (Newburyport, MA), model IL1700, with an SED240 detector for UVB (range 265–310 nm, peak
118 at 285 nm) or a SED033 detector for UVA (range 315–390 nm peak 365 nm) at a distance of 365
119 mm from the source, which was used for all experiments. In order to avoid artifactual thermal
120 effects of photon exposure on viral activity, cuvettes were placed on ice during irradiation. At 365
121 mm from the source, total solar UV intensity was 5.34 mJ/cm² s (UVA) and 0.28 mJ/cm² s (UVB).
122

123 ***2.4. HCoV-NL63 plaque forming assay and viral RNA quantification***

124 A published standard procedure was followed [15,21]. For HCoV-NL63, target cells (CaCo-2
125 or Calu-3) were seeded in 6-well plates at approximately 4×10^5 cells per well and incubated until
126 the monolayer was 80–90% confluent. Prior to infection, cells were washed with phosphate
127 buffered saline (PBS). Virus inoculum (MOI=0.01) in 500 μ L of growth media supplemented with
128 2% horse serum (with standard penicillin/streptomycin and L-glutamine supplementation) was
129 added to each well. Viral entry was performed by incubation at 4°C for 30-60 min with gentle
130 agitation followed by 1 h incubation in 33°C, 5% CO₂. Then, inoculum was removed and cells
131 were washed twice with PBS and replaced by 2 mL of normal growing media. After infection,
132 cells were washed twice with PBS and placed in the incubator and cultured in normal growth
133 media. Once plaques appeared (~5-7 d post infection), cells were fixed with 10% neutral buffered
134 formalin for 30 min at room temperature and stained with 1% crystal violet in 20% methanol for
135 20 min. Then, cells were washed several times with water, and plaques were counted and
136 representative pictures taken at 10x magnification using an inverted microscope (Nikon
137 Instruments, Melville, NY). In addition, viral RNA was extracted from cells and the respective
138 culture supernatant with the QIAamp Viral RNA Mini Kit (QIAGEN, Hilden, Germany). One step

139 RT-qPCR for HCoV-NL63 with absolute virus RNA quantification was performed using the
140 following primer/probe set as published before [22]:

141 forward primer – 5'-ACGTACTTCTATTATGAAGCATGATATTAA-3'

142 reverse primer – 5'-AGCAGATCTAATGTTATACTTAAACTACG-3'

143 probe – FAM-5'- ATTGCCAAGGCTCCTAAACGTACAGGTGTT -3'-NFQ-MGB

144 Briefly, RT-qPCR was carried out in a 20 µL reaction mixture with extracted RNA and One
145 step RT-qPCR 2x Master Mix containing ROX as a passive reference dye (Gold Biotechnology,
146 St. Louis, MO) and 300 nM forward and reverse primers and 200 nM MGB probe. Amplification
147 and detection were performed in ABI 7500 system (Applied Biosystems, Foster city, CA) under
148 the following conditions: first strand cDNA synthesis at 42°C for 30 min; initial denaturation/RT
149 inactivation at 95°C for 3 min; denaturation at 95°C for 10 sec and annealing/extension at 55°C
150 for 30 sec followed by 45 sec for data acquisition at 72°C. During amplification, the ABI PRISM
151 7500 sequence detector monitored real-time PCR amplification by quantitative analysis of the
152 fluorescence emissions. The reporter dye (FAM) signal was measured against the internal
153 reference dye (ROX) signal to normalize the signals for non-PCR-related fluorescence fluctuations
154 that occur from well to well. The cycle threshold (Ct) represented the refraction cycle number at
155 which a positive amplification was measured and was set at ten times the standard deviation of the
156 mean baseline emission calculated for PCR cycles 3 to 15. Genomic RNA from HCoV-NL63 was
157 used as a positive control.

158

159 ***2.5. SARS-CoV-2 plaque forming assay and viral RNA quantification***

160 The quantification of infectious SARS-CoV-2 has been published before [18]. Target cells
161 (Vero or Calu-3) were infected in triplicates at an MOI of 0.005 (high titer) or 0.001 (low titer).

162 Briefly, cells were incubated with SARS-CoV-2 for 2 h and subsequently overlaid with 1%
163 methylcellulose in culture medium. After 3-4 days, the cells were fixed in 10% neutral buffered
164 formalin for 30 min, washed under tap water, and stained with 1% crystal violet. The number of
165 plaques was counted on a light table. Alternatively, infection of cells was determined by measuring
166 the amount of viral RNA. Cells were lysed in Trizol followed by RNA extraction with the
167 RNAeasy kit (Qiagen). After reverse transcription, cDNA corresponding to the gene encoding the
168 SARS-CoV-2 spike protein was quantified by qPCR with the Perfecta FastMix (QuantaBio) using:
169 forward primer (SARS-CoV-2) 5'-GCTGGTGCTGCAGCTTATTA-3'
170 reverse primer (SARS-CoV-2) 5'-AGGGTCAAGTGCACAGTCTA-3'
171 at an annealing temperature of 60 °C. For normalization, *GAPDH* expression was measured using
172 the following primers:
173 forward primer (*GAPDH*) 5'-TGGTGAAGGTCGGTGTGAAC-3'
174 reverse primer (*GAPDH*) 5'-CCATGTAGTTGAGGTCAATGAAGG-3' .

175

176 ***2.6. Human Stress & Toxicity PathwayFinder RT² ProfilerTM gene expression array analysis of*** 177 ***infected host cells***

178 Seven days post infection of Calu-3 host cells with either HCoV-NL63 (MOI=0.01) or HCoV-
179 NL63 exposed to sUV (UVB portion: 706 mJ/cm²), total mRNA from host cells was isolated using
180 the RNeasy Mini kit (Qiagen, Valencia, CA) following our published standard procedures. Reverse
181 transcription was then performed using the RT² First Strand kit (Qiagen) from 500 ng total RNA.
182 For gene expression array analysis, the human Stress & Toxicity PathwayFinder RT² ProfilerTM
183 technology (Qiagen), assessing expression of 84 stress response-related genes, was used as
184 published before [23,24]. Quantitative PCR was run using the following conditions: 95 °C (10

185 min), followed by 40 cycles at 95 °C (15 s) alternating with 60 °C (1 min) (Applied Biosystems,
186 Carlsbad, CA). Gene-specific products were normalized to a group of 5 housekeeping genes
187 (*ACTB*, *B2M*, *GAPDH*, *HPRT1*, *RPLP0*) and quantified using the comparative $\Delta\Delta C_t$ method (ABI
188 PRISM 7500 sequence detection system user guide). Expression values were averaged across at
189 least three independent array experiments, and standard deviation was calculated for graphing and
190 statistical analysis as published before.

191

192 **2.7. Individual RT-qPCR analysis**

193 Total cellular mRNA was isolated using the Qiagen RNeasy Mini Kit (Qiagen, Gaithersburg,
194 MD) according to the manufacturer's protocol as published by us before [24]. Human primer
195 probes [*CCL3* (Hs_00234142_m1), *CSF2* (Hs_00929873_m1), *HSPA6* (Hs_00275682_s1), *IL1B*
196 (Hs_00174097_m1), *IL6* (Hs_00985639_m1), *SOD2* (Hs_00167309_m1), *TNF*
197 (Hs_00174128_s1), and *RSP18* (housekeeping gene; Hs_01375212_g1)], were obtained
198 from ThermoFisher Scientific (Waltham, MA). After cDNA synthesis, quantitative PCR reactions
199 were performed as follows: 10 min (95 °C) followed by 15 sec (95 °C), 1 min (60 °C), 40 cycles,
200 using the ABI7500 Real-Time PCR System (Applied Biosystems, Foster City, CA). Amplification
201 plots were generated, and Ct values were recorded as published before [24].

202

203 **2.8. Statistical analysis**

204 Unless stated differently, data sets were analyzed employing analysis of variance (ANOVA)
205 with Tukey's posthoc test using the GraphPad Prism 9.1.0 software (Prism Software Corp., Irvine,
206 CA); in respective bar graphs (analyzing more than two groups), means without a common letter
207 differ ($p < 0.05$) as published before [24]. For bar graphs comparing two groups only, statistical

208 significance was calculated employing the Student's two-tailed t-test, utilizing Excel (Microsoft,
209 Redmond, WA). Experiments were performed in sets of at least three independent repeats. The
210 level of statistical significance was marked as follows: * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$.

211

212 **3. Results**

213 ***3.1. Solar simulated UV exposure of HCoV-NL63 blocks subsequent viral infection and*** 214 ***replication in Calu-3 human epithelial lung cells***

215 First, we examined the feasibility of UV-inactivation of a pathologically relevant coronavirus
216 by employing a single dose of solar simulated UV light using a commercial xenon light source
217 with quantified spectral power distribution (Fig. 1A). To this end, we exposed human coronavirus
218 NL63 (HCoV-NL63) in PBS to a high dose of sUV [equivalent to approximately 6 minimal
219 erythemal doses (MEDs; UVA: 13.46 J/cm²; UVB: 706 mJ/cm²)] and subsequently used it to infect
220 Calu-3 target cells for 7 days [2, 6, 8]. We used unexposed virus as controls. Strikingly, sUV pre-
221 exposure strongly suppressed viral infectivity of target cells as demonstrated by quantitative
222 plaque assay analysis, indicating that sUV exposure caused a more than 8-fold decrease in viral
223 infectivity (Fig. 1B).

224 Next, we examined the dose-response relationship characterizing the inhibition of HCoV-NL63
225 viral replication (induced by sUV pre-exposure) by one step RT-qPCR analysis of the genomic
226 RNA copy number. We detected a significant inhibition at low sUV doses [UVA: 0.25 J/cm²; 13
227 mJ/cm² UVB]. Viral inactivation of more than 98 % occurred at doses equal and above 480 mJ/cm²
228 UVB (UVA: 9.04 J/cm²; Fig. 1C).

229

230

>Figure 1<

231 **3.2. Solar simulated UV exposure of HCoV-NL63 blocks subsequent infection of Caco-2 human**
232 ***epithelial colorectal cells***

233 In order to explore sUV effects on HCoV-NL63 infectivity in another human target cell, we
234 exposed the virus (in PBS) to a high dose of sUV [equivalent to approximately 6 MEDs (UVA:
235 13.46 J/cm²; UVB: 706 mJ/cm²)] and subsequently infected Caco-2 epithelial colon cells (Fig. 2).
236 As observed before with Calu-3 cells (Fig. 1), our quantitative plaque assay analysis showed that
237 the suppression of viral infectivity of Caco-2 target cells by sUV exposure caused a more than 4-
238 fold decrease in plaque formation (Fig. 2A). Likewise, our dose response analysis by RT-qPCR of
239 genomic RNA copy numbers indicated that sUV exposure caused a pronounced suppression of
240 HCoV-NL63 viral replication at doses as low as 240 mJ/cm² UVB (UVA: 4.52 J/cm²; Fig. 2B).

241

242 >Figure 2<

243

244 **3.3. Stress response gene expression array analysis confirms solar UV-induced inhibition of**
245 ***HCoV-NL63 infectivity targeting Calu-3 human epithelial lung cells***

246 Next, the cellular stress response of Calu-3 human epithelial lung cells, elicited by infection
247 with either mock-irradiated or sUV pre-exposed HCoV-NL63, was examined at the gene
248 expression level using the RT² Human Stress and Toxicity PathwayFinderTM PCR Array
249 technology. To this end, we infected Calu-3 target cells with sUV or mock-treated virus (doses as
250 in Figs. 1, 2) and profiled the gene expression at the end of the experiment. We observed global
251 HCoV-NL63-induced expression changes (antagonized by viral pre-exposure to sUV) as depicted
252 by Volcano plot (Fig. 3). As expected, HCoV-NL63 viral infection caused a pronounced
253 upregulation of stress response gene expression including genes encoding key regulators of

254 inflammatory signaling (such as *CSF2*, *TNF*, *IL1B*, *IL1A*, *CCL3*, *CXCL10*, *NFKBIA*, and *IL6*),
255 oxidative stress defense (such as *SOD2*), and heat shock response (such as *HSPA6*; Fig. 3). In
256 contrast, after viral sUV-exposure performed pre-infection, most of these infection-associated
257 expression changes were either attenuated or completely obliterated, an observation consistent
258 with pronounced suppression of HCoV-NL63 viral infectivity as a consequence of sUV-exposure.
259 Likewise, HCoV-NL63 viral infection-induced expression changes causing downregulation of
260 specific apoptotic modulators including *BCL2L1*, *EGR1*, *CASP8*, and *CASP1*, proliferation
261 markers such as *PCNA*, and heat shock response factors such as *HSPA4*, *HSPH1*, and *HSP90AA2P*
262 were completely absent in samples obtained from cells exposed to the pre-irradiated virus.
263 Strikingly, expression of seven specific genes (*CDKN1A*, *CYP11A1*, *MDM2*, *HMOX1*, *RAD50*,
264 *HSPA1L*, and *E2F1*) was modulated uniquely in response to exposure to sUV-preirradiated HCoV-
265 NL63, a finding consistent with gene expression changes responsive to sUV-induced chemical
266 damage to viral components (including ribonucleic acids, proteins, and lipids) [1-3].

267

268 >Figure 3<

269

270 ***3.4. Dose-response relationship of solar simulated UV-induced inhibition of SARS-CoV-2*** 271 ***infectivity targeting Vero and Calu-3 mammalian cells***

272 After demonstrating HCoV-NL63 coronavirus inactivation by sUV at an environmentally
273 relevant dose level, we examined whether sUV-inactivation might also be applicable to SARS-
274 CoV-2. To this end, we exposed the virus with a dose range of sUV, subsequently infected Vero
275 monkey epithelial cells at two different multiplicities of infection (MOIs, high versus low titer),
276 and measured the number of infectious virions three days later by plaque forming assay.

277 Strikingly, as observed with HCoV-NL63, sUV exposure caused a pronounced suppression of viral
278 infectivity. This antiviral effect, observable over a broad range of sUV doses, followed an
279 exponential decay curve with an effective ED₅₀ (sUV dose diminishing SARS-CoV-2 viral
280 infectivity by 50%) approximating 55 mJ/cm² (low titer) and 62 mJ/cm² (high titer) (Fig. 4A).

281 Next, we tested feasibility of achieving complete inhibition of SARS-CoV-2 replication by high
282 dose sUV [UVB portion: 1010 mJ/cm², a maximum dose level similar to the one used in the HCoV-
283 NL63-directed dose-response experiments (Fig. 1C)]. To this end, we pre-exposed SARS-CoV-2
284 to sUV and measured the amount of viral RNA (corresponding to the region of the viral genome
285 encoding the S protein) by RT-qPCR analysis. Indeed, complete inhibition was achieved at that
286 dose (Fig. 4B). We obtained similar results for sUV-exposed SARS-CoV-2 infections of Calu-3
287 human lung epithelial target cells with viral load in supernatants being monitored over three days
288 by RT-qPCR (Fig. 4C). Taken together, we conclude that SARS-CoV-2 is sensitive to sUV
289 suggesting viral inactivation at environmentally relevant exposure levels.

290

291 >Figure 4<

292

293 ***3.5. Solar simulated UV exposure of SARS-CoV-2 prevents stress response gene expression*** 294 ***elicited by viral infection of Calu-3 human epithelial lung cells as detected by array analysis***

295 Next, to determine Calu-3 human epithelial lung cell stress response gene expression elicited
296 by SARS-CoV-2 as a function of viral pre-exposure to sUV, we employed expression analysis
297 using the Human Stress and Toxicity PathwayFinder™ PCR Array technology. To this end, we
298 infected Calu-3 target cells with sUV or mock-treated virus as outlined before, followed by
299 comparative gene expression profiling at the end of the experiment. We observed multiple SARS-

300 CoV-2-induced expression changes (antagonized by viral pre-exposure to sUV) as shown in the
301 Volcano plot depiction [displaying statistical significance (P value) versus magnitude of change
302 (fold change)] (Fig. 5). SARS-CoV-2 infection caused a pronounced upregulation of stress
303 response gene expression including genes encoding key regulators of inflammatory signaling
304 including *IL1A*, *IL1B*, *IL6*, *TNF*, *CCL3*, *CXCL10*, *CSF2*, and *NFKBIA*, oxidative stress defense
305 such as *SOD2*, and heat shock response such as *HSPA6* (Fig. 5). In contrast, after infection with
306 sUV-exposed virus, most of these infection-associated expression changes were either attenuated
307 or completely obliterated, an observation consistent with pronounced suppression of SARS-CoV-
308 2 infectivity as a consequence of sUV-exposure. Remarkably, these expression changes closely
309 mirrored those observed in response to HCoV-NL63 infection that occurred with or without viral
310 exposure to sUV (Fig. 3).

311

312

>Figure 5<

313

314 Likewise, we observed a striking similarity between the gene expression changes elicited by
315 HCoV-NL63 and SARS-CoV-2 (and blocked by viral sUV pre-exposure), modulating redox,
316 inflammatory, and proteotoxic stress responses in Calu-3 human epithelial lung cells (Fig. 6).
317 Specifically, sUV-induced (UVB portion: 706 mJ/cm²) viral inactivation was apparent from
318 independent RT-qPCR assessment of mRNA levels ('no sUV' versus 'sUV') interrogating genes
319 encoding key regulators of redox (*SOD2*), inflammatory (*IL1B*, *TNF*, *CCL3*, *IL6*, *CSF2*), and
320 proteotoxic ('heat shock'; *HSPA6*) stress responses in Calu-3 target cells as detailed above. Thus,
321 our data suggest that similar to HCoV-NL63, sUV exposure of SARS-CoV-2 interrupts the viral

322 life cycle causing suppression of viral replication and virus-induced inflammatory and cellular
323 stress responses in mammalian target cells.

324

325 >Figure 6<

326

327 **4. Discussion**

328 Identification and mechanistic exploration of environmental factors that might determine
329 coronavirus infectivity are of significant interest with relevance to both basic molecular research
330 and public health-related preventive and interventional investigations [2]. Here, we have explored
331 for the first time the effects of full spectrum (UVA + UVB) solar ultraviolet radiation on
332 coronavirus infectivity and demonstrate that sUV inactivates HCoV-NL63 and SARS-CoV-2
333 coronaviruses at environmentally relevant doses. First, we observed that exposure of HCoV-NL63
334 and SARS-CoV-2 to sUV (performed at acute dose levels relevant to human populations
335 worldwide) blocks subsequent viral infection and replication in relevant primate target cells
336 [human: Calu-3 lung epithelial, Caco-2 colorectal epithelial; monkey: Vero kidney epithelial (Figs.
337 1, 2, 4)]. Blockade of viral infectivity in response to sUV pre-exposure was also confirmed using
338 stress response gene expression profiling in array (Figs. 3, 5) and independent RT-qPCR format
339 (Fig. 6) elicited in Calu-3 target cells by coronavirus infection (HCoV-NL63 and SARS-CoV-2).

340 Remarkably, dose levels used throughout this pilot study are representative of terrestrial ground
341 level exposure suggesting environmental relevance, and significant coronavirus inactivation was
342 detectable even at low exposure levels expected to be beneath the cutaneous sunburn-inducing
343 threshold (Figs. 1, 2, 4) [2,6,8]. In this context, it is remarkable that recent research has already
344 indicated that ground level solar UV displays significant virucidal effects targeting coronaviruses

345 including SARS-CoV-2 [2,6,11,13]. However, the complexity of human exposure levels to solar
346 UV as a function of solar zenith angle, seasonality, spectral distribution, and latitude remain to be
347 addressed before any firm conclusions relevant to human populations can be drawn. Specifically,
348 the anti-viral activity of specific spectral components of sUV remains to be determined since the
349 light source employed in our prototype studies emitted full spectrum simulated solar UV, and the
350 action spectrum of virus inactivation by solar UV remains largely undefined. For example, it is
351 possible that the UVA portion of ground level sUV significantly contributes to the coronavirus-
352 directed effects described by us [7]. It therefore remains to be seen if indirect impairment of viral
353 structure and infectivity occurs by alternative mechanisms, such as UVA-driven photosensitization
354 and oxidative stress (mediated by formation of reactive oxygen species including singlet oxygen),
355 that might be operative in addition to direct inactivation of viral genomic RNA through nucleic
356 acid base photodamage. It will also be interesting to explore potential mechanistic synergisms
357 underlying virucidal effects that occur upon combined UVA and UVB as compared to separate
358 spectral exposure. Likewise, experimental conditions used throughout our studies (including viral
359 irradiation in PBS and exposure performed in cell culture medium) might limit the applicability of
360 our conclusions in the context of relevant coronavirus transmission situations that involve more
361 complex determinants of infectivity including the role air-borne and aerosol transmission and
362 intermediate surface retention [6].

363 Addressing urgency and global scale of the unfolding SARS-CoV-2 pandemic requires an
364 improved understanding of environmental factors that modify viral infectivity [2,6,8]. Taken
365 together, our data suggest feasibility of sUV-induced viral inactivation targeting HCoV-NL63 and
366 SARS-CoV-2 coronaviruses, a finding to be substantiated by future mechanistic exploration
367 performed in more relevant *in vivo* exposure models.

496 **Figure 1. Solar simulated UV pre-exposure antagonizes HCoV-NL63 viral infectivity**
497 **targeting Calu-3 human epithelial lung cells.** Virus in PBS was exposed to sUV or left
498 unexposed followed by Calu-3 target cell infection (0.01 MOI) and post infection culture over 7
499 days followed by analysis. (A) Spectral power distribution (irradiance) of the solar simulator light
500 source equipped with appropriate cut-off filter (sUV: UVB + UVA, solid black line). (B) Plaque
501 assay after viral exposure to sUV (UVB portion: 706 mJ/cm²) as visualized by light microscopy
502 (10 x magnification); bar graph summarizes numerical data. (C) RT-qPCR of viral genome
503 replication in target cells [left panel: amplification curves as a function of sUV dose (UVB portion
504 as indicated); right panel: bar graph summarizing numerical data].

505
506 **Figure 2. Solar simulated UV pre-exposure antagonizes HCoV-NL63 viral infectivity**
507 **targeting Caco-2 human epithelial colorectal cells.** Virus in PBS was exposed to sUV or left
508 unexposed followed by Caco-2 target cell infection (0.01 MOI) and post infection culture (7 days)
509 followed by analysis. (A) Plaque assay after viral exposure to sUV (UVB portion: 706 mJ/cm²)
510 as visualized by light microscopy (10 x magnification); bar graph summarizes numerical data. (B)
511 RT-qPCR detection of viral genome replication in target cells; left panel: amplification curves (as
512 a function of sUV-dose); right panel: bar graph summarized numerical data.

513
514 **Figure 3. Solar simulated UV pre-exposure of HCoV-NL63 prevents stress response gene**
515 **expression elicited in Calu-3 human epithelial lung target cells.** Treatments were performed as
516 detailed in Fig. 1. (A) Target cell stress response [control (HCoV-NL63) versus sUV (UVB
517 portion: 706 mJ/cm²) pre-exposed virus] assessed by *RT² ProfilerTM Stress and Toxicity Pathway*

518 gene expression array analysis [volcano plot depiction: p value over log₂ (fold expression
519 change)]. (B) Scatter plot depiction comparing expression changes elicited by untreated control
520 virus (top panel) or sUV pre-exposed virus (bottom panel). (C) Venn diagram depicting expression
521 changes induced by mock-irradiated virus (control) versus sUV pre-irradiated virus. (D) Tabular
522 summary of numerical values specifying gene expression changes at the mRNA level (p<0.05).

523

524 **Figure 4. Solar simulated UV exposure of SARS-CoV-2 antagonizes subsequent viral**

525 **infection and replication in African green monkey Vero and Calu-3 human epithelial lung**

526 **cells.** (A) SARS-CoV-2 was sUV-irradiated (UVB portion: up to 480 mJ/cm²; or remained

527 unirradiated) in PBS and subsequently used to infect Vero cells at two different MOIs (high versus

528 low titer). Dose response of plaque formation as a function of sUV pre-exposure dose was

529 assessed; a representative experiment (left panel, top and bottom rows) and quantification (right

530 panels) are depicted. (B) Detection of viral genome replication in Vero cells with quantification

531 of viral RNA after infection using mock or sUV pre-irradiated virus (UVB portion: 1010 mJ/cm²)

532 as assessed by RT-qPCR after 24 h. (C) Infection of Calu-3 cells with SARS-CoV-2 [sUV pre-

533 exposed (UVB portion: 706 mJ/cm²) versus unirradiated virus]. The presence of infectious virions

534 in the supernatants was quantified over the course of three days post infection by RT-qPCR (nd:

535 not detectable).

536

537 **Figure 5. Solar simulated UV pre-exposure of SARS-CoV-2 prevents stress response gene**

538 **expression elicited in Calu-3 human epithelial lung target cells.** Treatment and analysis were

539 performed as detailed in Fig. 3. (A) Target cell stress response [control (SARS-CoV-2) versus

540 sUV (UVB portion: 706 mJ/cm²)-preirradiated virus] assessed by *RT² ProfilerTM Stress and*

541 *Toxicity Pathway* gene expression array analysis [volcano plot depiction: p value over log₂ (fold
542 expression change)]. (B) Scatter plot depiction comparing expression changes elicited by untreated
543 control virus (top panel) or sUV pre-exposed virus (bottom panel). (C) Venn diagram depicting
544 expression changes induced by mock-irradiated virus (control) versus sUV pre-irradiated virus.
545 (D) Tabular summary of numerical values of gene expression changes at the mRNA level (p<0.05).

546
547 **Figure 6. Comparative analysis of redox, inflammatory, and proteotoxic stress response gene**
548 **expression in Calu-3 human epithelial lung cells elicited by HCoV-NL63 and SARS-CoV-2**
549 **(with and without viral sUV pre-exposure).** Gene expression as assessed by single RT-qPCR
550 quantification in virus-exposed target cells as a function of viral pre-exposure [‘no sUV’ versus
551 ‘sUV’ (UVB portion: 706 mJ/cm²)]. Bar graphs depict fold change (‘sUV’ versus ‘no sUV’)
552 normalized to housekeeping gene expression (*RPS18*; gray bar: no sUV pretreatment; black bar:
553 sUV-pretreatment).
