26 **Running title:** xenogeneic fibroblasts inhibit cancer cell growth *in vitro*
27

28

29 **ABSTRACT**

30 Cell-based therapies cure some hematologic malignancies, although little information exists on
31 solid cancer cell responses. The study objective was to test the hypothesis that xenogeneic
32 fibroblasts can inhibit the growth of human cancer cell lines *in vitro*. Seven human cell lines
33 (pancreatic cancer HPAF II; brain cancer U-87 MG; fibrosarcoma; ovarian cancer OVCAR3 and
34 SKOV3; and breast cancer MCF7 and MDA-MB231) were co-cultured with two xenogeneic
35 fibroblast cell lines (CV-1; monkey, *Cercopithecus aethiops* and DF-1; chicken, *Gallus gallus*) in
36 a transwell culture system. Cancer cell proliferation was assessed colorimetrically. Different
37 concentrations of breast and ovarian cancer cells were tested. Gene expression induced by DF-1
38 xenogeneic fibroblasts was assessed by RNAseq of MCF7 breast cancer cells. The proliferation
39 of the majority of the cancer cell lines was altered by co-culture with xenogeneic fibroblasts.
40 Cell proliferation was increased (4-17%) by CV-1; DF-1 increased brain cancer cell proliferation
41 (16%), decreased breast and ovarian cancer cell growth (15 and 26% respectively) but did not
42 affect fibrosarcoma and pancreatic cancer cells. When the initial cancer cell concentrations were
43 lowered 4-fold, growth inhibition of breast and ovarian cancer increased more than 2-fold. DF-1
44 fibroblasts induced significant differential expression of 484 genes in MCF7 breast cancer cells;
45 285 genes were down-regulated and 199 genes were upregulated compared to control. Genes
46 involved in the immune response were the major downregulated entities. RNAseq results were
47 validated by qRT-PCR of 12 genes. The results show that xenogeneic fibroblasts can alter the
48 growth and gene expression of cancer cells *in vitro*. This suggests a potentially novel
49 investigational approach to the control of cancer cell growth.

60

61 INTRODUCTION

62 Metastatic cancer remains a lethal disease despite numerous advances in cancer treatment.
63 Although existing cancer treatments such as surgery, radiotherapy, and chemotherapy can
64 achieve a cure in some early-stage cancers, they have only a palliative effect in advanced
65 cancers. In addition, they often have complications and toxicities. For some malignancies with a
66 single gene defect, treatment progress and sometimes a cure is achieved by "targeted" drugs such
67 as the PARP inhibitor olaparib for ovarian cancer in women with germline BRCA mutations [1,
68 2] and imatinib which targets BCR-ABL tyrosine kinase in Philadelphia chromosome-positive
69 chronic myelogenous leukemia [3]. However, in the majority of cases, the common epithelial
70 malignancies (e.g., colon, breast, lung, liver, pancreas and ovary) have multiple genetic
71 alterations that often involve deletion and amplification of large parts of the genome, as well as
72 complex and interacting cellular and molecular networks. Consequently, the success of single-
73 target therapies or even their combinations is often limited.

74 A potential alternative to targeted therapies is cytotherapy. Cytotherapy has been successfully
75 used to treat cancer. Although commonly used in experimental conditions cells include
76 mesenchymal stem cells (MSC) and fibroblasts, a variety of other cells were investigated [4, 5].
77 For example, CAR-T (chimeric antigen receptor) cell therapy was recently developed and FDA-
78 approved for some forms of leukemia [6].

79
80 Xenogeneic cytotherapies have shown some promise. Xenogeneic cells have the potential to
81 stimulate the immune system to overcome tumor immunosuppression [7-9]. An influx of
82 immune cells and tumor regression occurred in patients with solid metastatic tumors in a Phase I
83 clinical trial in which xenogeneic African green monkey fibroblasts, engineered to produce
84 human IL-2, were administered intratumorally [10]. Likewise, targeted cytotherapy for
85 pancreatic cancer using naïve, non-engineered rat umbilical cord matrix derived stem cells to
86 control the growth of pancreatic cancer, strongly attenuated the growth of pancreatic carcinoma
87 cells *in vitro* and *in vivo* in a peritoneal mouse model [11]. Xenogeneic immunization with
88 tyrosine hydroxylase-derived DNA vaccines was effective against neuroblastoma in mice [12].
89 In a human clinical trial performed in Russia, irradiated xenogeneic murine cell vaccines were
90 effective in breaking the immune tolerance to human tumor-associated antigens in human
91 colorectal cancer [13].

92
93 One appeal of cell therapy is that cells may express and secrete thousands of biologically active
94 molecules which could interfere with malignant growth. Also, specific cells, such as stem cells
95 or fibroblasts, can migrate to the corresponding tissue/organ ("homing") or at least in the case of
96 mesenchymal stem cells, to the site of injury, inflammation or cancer [14, 15]. Once "homed" to
97 the tumor, xenogeneic fibroblasts can potentially elicit a robust immune response to the tumor.
98 Cancer-associated fibroblasts play a fundamental role in modulating the behavior of cancer cells
99 and cancer progression [15, 16]. There is evidence for both pro- and anti-tumor actions of
100 cancer-associated fibroblasts [17]. Interestingly, normal human and murine fibroblasts inhibit
101 the proliferation and motility of prostate tumor cell lines when co-cultured *in vitro* [18]. This
102 effect involved both cell contact with fibroblast monolayers and fibroblast secreted
103 biomolecules.

104 The objective of the study was to assess the effect of xenogeneic fibroblasts on cancer cells in
105 order to test the hypothesis that xenogeneic fibroblast cell lines can inhibit the growth of human
106 cancer cell lines *in vitro*. The approach was to use a simplified system of exposing cancer cells
107 to xenogeneic fibroblasts *in vitro* in which cells are separated in a transwell system. Cancer cell
108 growth and molecular expression changes in cancer cells were examined.

109

110

111 METHODS

112

113 Cell Culture

114

115 All cell lines were obtained from the American Type Culture Collection (ATCC; Manassas,
116 VA). The two fibroblast cell lines included UMNSAH/DF-1 (henceforward designated DF-1)
117 derived from normal *Gallus gallus* (chicken) embryo fibroblasts (ATCC CRL12203) and CV-1
118 derived from normal *Cercopithecus aethiops* (African green monkey) kidney fibroblasts (ATCC
119 CCL70). The seven human cancer cell lines included those from pancreatic cancer HPAF II
120 (ATCC CRL1997); brain cancer U-87 MG (ATCC HTB14); fibrosarcoma (ATCC CCL121);
121 ovarian cancer OVACAR3 (ATCC HTB161) and SKOV3 (ATCC HTB77); and breast cancer
122 MCF7 (ATCC HTB22) and MDA-MB231 (ATCC HTB26). After experiments at a fixed
123 starting cancer cell concentration, the two breast cancer cell lines and two ovarian cancer cell
124 lines were selected to explore the effects of initial cancer cell concentrations on growth effects in
125 co-culture with the chicken embryo-derived fibroblast cell line. The breast cancer cell lines were
126 estrogen and progesterone receptor-positive (MCF7) or estrogen and progesterone-negative
127 (MDA-MB231); ovarian cancer cell lines included a p53 mutant cell line (OVCAR3) and a p53
128 wild-type cell line (SKOV3).

129

130 Cells were cultured in Eagles Essential minimum media (ATCC) containing 10% fetal bovine
131 serum (FBS) (Sigma; St. Louis, MO) in a humidified incubator (5% CO₂) at 37°C. Cancer cells
132 were co-cultured with fibroblast cell lines using a transwell system (Greiner Bio-one Thincert™;
133 Monroe, NC) with fibroblasts layered in the upper well (Figure 1). Cancer cells were seeded at
134 4x10⁴ cells/well/800 µl of media and fibroblast cells in the insert at 2x10⁴ cells/300 µl media. As
135 a control, the matching cancer cells were used in both the well and insert with the cancer cells in
136 the insert at 2x10⁴ cells/300 µl media.

137

138 Cultures were monitored for mycoplasma contamination. Also, RNA sequencing data were
139 analyzed for mycoplasma sequences. The data were uploaded into the Galaxy server, four
140 million reads from each file were selected using the "split file tool," and the split FASTQ
141 sequencing file aligned using "Bowtie2" against three mycoplasma fasta sequences (*M.*
142 *fermentans* M64, *M. hominis* ATCC 23114 and *M. hyorhinae* MCLD) commonly found in cell
143 cultures [19]. No alignment with the mycoplasma sequences was found, supporting a lack of
144 mycoplasma contamination.

145

146 Cell Growth

147

148 After five days, the growth of the cancer cells was measured using the MTT (3-(4,5-
149 dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) cell proliferation assay. The reduction of
150 yellow tetrazolium dye (MTT) by living cells produces purple formazan crystals. In brief, the
151 inserts were removed, and 80µl of 5 mg/ml MTT reagent (MP Biomedicals; Santa Ana, CA) was
152 added to each well and incubated for 4 hours. The media was removed, and the intracellular
153 formazan solubilized by adding 500 µl of DMSO (Sigma; St. Louis, MO) and incubating for 30
154 minutes at room temperature. Optical density was read at 560 nm with a reference wavelength of
155 650 nm using an Epoch spectrophotometer (BioTek Instruments; Winooski, VT). The percent
156 change in growth compared to the control incubations was calculated. The experiment was

157 repeated three times for cell growth assays and RNA extraction. The data were analyzed using
158 the Student's t-test with $p < 0.05$ considered significant.

159

160 **RNA Extraction**

161

162 The effect of the DF-1 fibroblast cell line on gene expression changes in human MCF7 breast
163 cancer cells was determined. The media was removed after co-culture for five days, and the
164 culture wells were washed with cold phosphate-buffered saline (PBS). RNA was extracted with
165 100 μ l of Trizol per well, triplicate wells were pooled, and the Trizol extractions continued
166 according to the manufacturer's protocol. Precipitated RNA was solubilized in 40 μ l of molecular
167 biology grade water (RPI Research Products; Mount Prospect, IL) and stored at -80°C . RNA
168 quantity and quality was measured in a NanoDrop Spectrophotometer. Novogene checked RNA
169 integrity with an Agilent 2100 analyzer, and RNA degradation was assessed by gel
170 electrophoresis before subjecting the sample to Next-Generation sequencing.

171

172 **Next-Generation Sequencing**

173

174 The extracted RNA was sent to Novogen Inc. (Davis, CA) for sequencing. cDNA libraries were
175 made from the RNA as per the in-house Novogene protocol. Paired-end (PE-150bp) sequencing
176 was performed using the Illumina sequencing platform; each RNA sample was sequenced to
177 obtain at least 40 million reads per sample. The RNA sequence data was "cleaned" using the
178 NOVOGENE default protocol to remove the adapter sequences, reads containing more than 10%
179 N (sequence not determined) and reads with a low-quality Phred score (Q Score ≤ 5)
180 (Supplementary Table 1).

181

182 The cleaned data was uploaded to Galaxy (<https://usegalaxy.org/>) for analysis. Sequence
183 count per gene was determined using the "Salmon" method in Galaxy. The Salmon program
184 quantifies the expression of transcripts from RNAseq data; it indexes, quantifies, and provides
185 the count per each transcript aligned to the reference genome [19]. The count files from each
186 sample are merged into one list and uploaded to the Degust webserver for differential gene
187 expression (DE) analysis between groups. The data was further filtered to remove "no count"
188 transcripts by using criteria of at least one count per transcript in all samples. EdgeR
189 implemented in the Degust (<http://degust.erc.monash.edu/>) was used to identify differentially
190 expressed genes (FDR = 0.01 and absolute log fold change = ± 0.5), using the quasi-likelihood
191 functionality of edgeR; DE genes lists were analyzed further for functional enrichment using the
192 "Reactome pathway browser" at <https://reactome.org/PathwayBrowser/>.

193

194 **qRT-PCR**

195

196 Examples of differentially expressed genes were selected for confirmation and validation:
197 interleukin 1 receptor, type I, cysteine-rich secretory protein 3, KIT ligand, selectin L, G protein-
198 coupled estrogen receptor 1, protein kinase C, delta, interleukin 1 receptor antagonist, chemokine
199 (C-X-C motif) ligand 12, CD36 molecule (thrombospondin receptor), B-cell CLL/lymphoma 2,
200 Janus kinase 2, and interleukin 18. The qRT PCR primers were designed using NCBI primer
201 blast. One microgram of total RNA was treated with DNASE (Thermo Fischer; Waltham, MA)
202 to remove any genomic DNA contamination according to the manufacturer's standard protocol.

203 Five hundred ng of DNASE treated RNA was used for the first-strand synthesis using an ABI
204 high-capacity cDNA reverse transcription kit (Applied Biosystems; Foster City, CA). qRT-PCR
205 was carried out using Fast Sybr green (ABI). Ct values were exported, and the ddCt value was
206 used to calculate fold change in differential expression.

207

208 **RESULTS**

209 **Cell growth**

210 The proliferation of the majority of the cancer cell lines was altered by transwell co-culture with
211 xenogeneic fibroblast cell lines.

212 Specifically, CV-1 fibroblasts increased the proliferation of brain cancer cells by 12%, OVCAR3
213 ovarian cancer cells by 13.5% and fibrosarcoma cells by 11% compared to control. These
214 changes were significant ($p < 0.05$). The growth of the pancreatic cancer cell line increased 20%
215 in two out of three experiments, while growth of the MCF7 breast cancer cell line did not
216 increase significantly (Figure 2A).

217 DF-1 fibroblasts had mixed effects on cancer cell line growth. Brain cancer cell proliferation
218 increased 16%. The growth of MCF7 breast cancer cells was reduced 25% and OVCAR3
219 ovarian cancer cell growth was reduced by 14% compared to control ($p < 0.05$). The pancreatic
220 cancer and the fibrosarcoma cell lines showed no significant growth change in co-culture with
221 either fibroblast cell line (Figure 2B).

222 To assess the effect of different initial cancer cell concentration (10,000, 20,000 and 40,000) on
223 cell growth in the presence of xenogeneic fibroblasts, proliferation was examined for the breast
224 and ovarian cancer cell lines in co-culture with DF-1 fibroblasts. Inhibition was higher overall at
225 lower starting cell concentrations (Figure 3) except for OVCAR3 where inhibition was higher at
226 the highest cell concentration. Thus the growth effects differed between the two ovarian cancer
227 cell lines. The pattern was similar for either breast cancer cell lines regardless of estrogen and
228 progesterone receptor absence (e.g., MDA-MB231 cells) or presence (e.g., MCF7 cells).

229 **Gene Expression**

230 Gene expression was examined in the MCF breast cancer cell line in response to DF-1
231 fibroblasts. Overall, 484 genes were significantly differentially expressed; of these, 285 genes
232 were down-regulated and 199 genes were up-regulated compared to control. The results of
233 Reactome analysis show the major functional pathways that are differentially up-regulated
234 (Table 1A) and down regulated (Table 1B). Immune pathway genes ($n = 101$ entities found)
235 were the major over-represented group among the downregulated genes. Among the upregulated
236 genes those involved in developmental pathways were the most overrepresented genes ($n=27$
237 entities found). An MA plot of the distribution of significantly up and down-regulated genes is
238 shown in Figure 4.

239 To validate the RNA sequencing data, 12 genes with a significant fold change in expression were
240 chosen and quantified by qRT-PCR. The results of qRT-PCR supported those obtained from
241 transcriptome analysis and demonstrated a similar up- or down-regulation of the genes (Table 2).

242

243

244 **DISCUSSION**

245 The proliferation of a majority of the cancer cell lines was altered by co-culture with xenogeneic
246 fibroblasts. The direction of the effect varied with different cell combinations. The DF-1
247 chicken embryo-derived fibroblast cell line most effectively inhibited breast and ovarian cancer
248 cell lines. Associated genomic changes in breast cancer cells showed that in addition to the
249 expected changes in proliferation and differentiation pathways, downregulation of components
250 of immune system pathways was the most dramatic change of the cancer cells.

251 These findings are significant since cancer-associated fibroblasts are an active component of the
252 tumor microenvironment and they coordinate interactions between the cancer cells and stromal
253 cells [15, 17]. Fibroblasts are known to remodel tumor stroma and can have pro- and anti-tumor
254 effects [16, 21]. In this study, the difference between monkey and chicken fibroblasts effects on
255 cell growth could be due to a number of factors. Aside from the obvious difference in species
256 origin, the monkey fibroblasts are from adult kidney while chicken fibroblasts were from
257 embryos that are pluripotent and could produce a different and greater range of active factors.
258 Interestingly, exposure to embryonic microenvironment(s) of chicken or zebrafish reprograms
259 human melanoma cells and inhibits tumor development [22]. Fibroblasts are a dominant
260 component of tumor stroma and play a key role in regulating the anti-tumor immune response
261 [5]. Thus, the results of RNA-seq in this study are consistent with a major effect on immune
262 system pathways.

263 Immunotherapy became an important new development in treatment of multiple malignancies
264 and after more than 100 years of basic research and clinical trials, finally proved that
265 manipulating the host immune system can lead to a clinically significant anti-tumor effect.
266 However, the percentage of patients with advanced solid tumors who achieve a durable response
267 or cure from immunotherapy remains small [23]. Immunotherapy employs monoclonal
268 antibodies to biomarkers present on immune cells such as PD-L1 or CTLA-4 [23], and assumes
269 all relevant targets are addressed. A potential advantage of cell therapy is that multiple factors
270 are produced by therapeutic cells, which could address multiple targets.

271 Xenogeneic cell and organ transplantation has been used to replace damaged cells in Parkinson's
272 disease (DA neurons), diabetes (islets) and liver and heart failure [7]. Xenogeneic cell
273 transplantation has been proposed as a therapeutic approach to re-activate anti-tumor immunity
274 and restore impaired function [7]. Various cell types and preparations have been used as a
275 cancer therapy [8]. Human, mouse and rat MSCs transfected with various vectors (e.g. viruses,
276 transposon-based gene vectors) attenuated growth of different tumors targeted by each individual
277 genetically engineered group of MSCs [24]. A composite xenogeneic polyantigenic vaccine
278 prepared from murine melanoma B16 and carcinoma LLC cells increased survival and tumor
279 immunity (e.g., increased T cell responses to human Caco-2 colon adenocarcinoma-associated
280 antigens) in stage IV colorectal cancer patients [13]. Xenogeneic monkey fibroblasts (Vero
281 cells) genetically engineered to produce human IL-2 were administered intra-tumorally; this
282 treatment was associated with an anti-tumor effect [10]. A vaccine using xenogeneic whole
283 endothelial cells effectively inhibited tumor growth, induced regression of established tumors
284 and prolonged survival of tumor-bearing mice [9]. Fibroblasts inhibited cancer cell growth in
285 co-culture; this inhibition varied depending on the source and the site of origin of the fibroblasts
286 [18].

287 Caveats and considerations for this study are related to the heterogeneity of fibroblast functions.
288 A uniform effect of fibroblasts was not expected since subsets of cancer associated fibroblasts
289 have cancer-suppressing or cancer-promoting functions [15, 16]. Furthermore, fibroblasts have
290 intrinsic cellular plasticity and exhibit heterogeneity in tumors [25]. Activated fibroblasts, which
291 have similar features to mesenchymal stromal cells, may be capable of reprogramming into
292 different lineages, including endothelial cells, adipocytes, and chondrocytes [17]. The function
293 of the co-cultured fibroblasts may differ when paired with different cell lines. A future study
294 would reveal the effect of fibroblasts in direct contact with cancer cells in co-culture.

295 Finally, this simplified system was used to gain knowledge of the effect of xenogeneic
296 fibroblasts on cancer cells. However, it does not include the complex interactions that might
297 occur *in vivo*; in other words, would the chicken fibroblast cell line drive the same response *in*
298 *situ*? While there is interest in the development of fibroblast-targeted cancer therapies, the
299 complexities of fibroblast-cancer cell interactions remain to be adequately understood before
300 novel therapies targeting or exploiting fibroblasts can be implemented [5].

301 **CONCLUSION**

302 The results of the studies showed that xenogeneic fibroblasts can inhibit proliferation of human
303 ovarian and breast cancer cells *in vitro*. Furthermore, this growth inhibition was associated with
304 differential expression of genes and genomic pathways involved in cell proliferation,
305 differentiation, and immune function. Thus, the co-culture experiments suggest that xenogeneic
306 cells may affect not only tumor cell growth and differentiation, but also, their interactions with
307 immune system.

308 Future directions will include analysis of biomolecules secreted by chicken embryonic
309 fibroblasts in paracrine fashion in co-culture. These biomolecules may have human homologs
310 with potential utility in cancer treatment. We are also planning to explore this phenomenon
311 further *in vivo* using animal models.

FIGURE LEGENDS

413 **Figure 1.** Diagram of transwell used for co-culture of fibroblasts and cancer cell lines

414 Legend: In the experimental wells, cancer cells were seeded in the lower chamber and fibroblasts were
415 seeded in the upper well. In the control wells the same cancer cells were seeded in the top and bottom
416 wells without added fibroblast cell lines. Upper wells contained 2×10^4 cells/300 μ l media.

417

418 **Figure 2.** Xenogeneic fibroblast cell lines alter cancer cell growth in co-culture

419 Legend: The proliferation of a majority of the cancer cell lines was increased significantly ($p < 0.05$) in
420 the presence of CV-1 fibroblasts (monkey; *C. aethiops*) (upper panel). The percent change in growth is
421 shown for brain cancer (HTB14 cells), ovarian cancer (HTB161 line of OVACR3 cells), fibrosarcoma
422 (CCL121 cells) and pancreatic cancer (HPAF II and CRL1997 cells) compared to the control. The small
423 increase in the breast cancer cell line MCF7 (HTB22) growth was not significant.

424 The DF-1 (chicken; *G.gallus*) embryo-derived fibroblast cell line had mixed effects on the cancer cell
425 lines (lower panel); the growth of brain cancer increased but the growth of breast cancer MCF7 (HTB22)
426 and OVCAR3 was reduced compared to the control ($p < 0.05$). The pancreatic cancer cell line (HPAF II,
427 CRL1997) and the fibrosarcoma cell line (CCL121) showed no significant change in response to DF-1
428 cells.

429 All experimental wells were seeded at 4×10^4 cancer cells/well/800 μ l of media along with 2×10^4 cells/300
430 μ l media fibroblast cells in the transwell insert. Controls consisted of adding matched cancer cells to the
431 transwell.

432

433 **Figure 3.** Cancer cell concentration and inhibition of their growth by chicken embryo-derived fibroblast

434 Legend: Inhibition of cancer cell line growth by DF-1, (chicken; *G.gallus*) embryo-derived fibroblast cell
435 line, is greater at lower initial cancer cell numbers.

436

437 **Figure 4.** MA plot of significantly up- and downregulated genes in response to DF-1 fibroblasts

438 Legend: MA plot shows the distribution of significantly ($p < 0.05$) up- and downregulated genes in
439 response to DF-1 xenogeneic fibroblasts as a fold change (FC) in expression.

440

TABLE LEGENDS

441 **Table 1.** Selected genes from Reactome analysis with altered expression by RNAseq of the MCF7 breast
442 cancer cell line in response to DF-1 xenogeneic fibroblasts are shown. There were more (B)
443 downregulated (n=285) than (A) upregulated (n=199) entities. The top 10 with up- or downregulated
444 expression are shown. Overall the p values were more significant for downregulated genes. The major
445 changes in expression in the cancer cells involved the immune system.

446

447 **Table 2.** Changes in expression of selected genes seen in next generation sequencing (NGS) were
448 confirmed by qPCR.

449 **Table 1.** Selected genes in MCF7 breast cancer cell line with altered expression after exposure to DF-1
 450 fibroblasts
