13 **Abstract**

14 Integrity of mitochondrial DNA (mtDNA), encoding several subunits of the respiratory chain, is

15 essential to maintain mitochondrial fitness. Mitochondria, as a central hub for metabolism, are

16 affected in a wide variety of human diseases but also during normal ageing, where mtDNA

17 integrity is compromised. Mitochondrial quality control mechanisms work at different levels, and

18 mitophagy and its variants are critical to remove dysfunctional mitochondria together with

19 mtDNA to maintain cellular homeostasis. Understanding the mechanisms governing a selective

20 turnover of mutation-bearing mtDNA without affecting the entire mitochondrial pool is

21 fundamental to design therapeutic strategies against mtDNA diseases and ageing. Here we

22 show that mtDNA depletion after expressing a dominant negative version of the mitochondrial

23 helicase Twinkle, or by chemical means, is due to an exacerbated mtDNA turnover. Targeting of

24 nucleoids is controlled by Twinkle which, together with the mitochondrial transmembrane

25 proteins ATAD3 and SAMM50, orchestrate mitochondrial membrane remodeling to form

26 extrusions. mtDNA removal depends on autophagy and requires the vesicular trafficking protein

27 VPS35 which binds to Twinkle-enriched mitochondrial subcompartments upon mtDNA damage.

28 Stimulation of autophagy by rapamycin selectively removes mtDNA deletions which

29 accumulated during muscle regeneration *in vivo*, but without affecting mtDNA copy number.

30 With these results we unveil a new complex mechanism specifically targeting and removing

31 mutant mtDNA which occurs outside the mitochondrial network. We reveal the molecular targets

32 involved in a process with multiple potential benefits against human mtDNA related diseases,

33 either inherited, acquired or due to normal ageing.

36

37

INTRODUCTION

The accumulation over time of mutations in the mitochondrial genome (mtDNA) is a common process which has been shown to occur in many tissues [1] and is probably one of the hallmarks of aging [2]. MtDNA is present in thousands of copies per cell, hence, impairment of mitochondrial function is observed only when the percentage of mutated mtDNA molecules surpasses a specific threshold[3].

Cells possess a plethora of quality control mechanisms to survey the intactness of DNA, RNA and proteins, but also of entire organelles. In addition to bulk autophagy, which is responsible for the continuous and non-selective turnover of cellular material activated during nutrient shortage, specific mechanisms are initiated to remove malfunctioning organelles upon damage. The process of mitophagy has been investigated extensively in recent years as an important salvage pathway to remove dysfunctional mitochondria [4]. The ongoing fission and fusion events of the dynamic mitochondrial network are important processes in order to survey mitochondrial quality by predisposing those parts of the network with impaired function to degradation. Mitochondrial fission is a requirement to initiate mitophagy of damaged mitochondria [4], whereas knockout of key players of mitochondrial fusion has been shown to induce mtDNA instability, either by causing a rapid accumulation of mtDNA alterations over time [5] or by mtDNA depletion [6].

Recently, a process with a high level of specificity involving mitochondrial derived vesicles (MDVs) was shown to remove not the complete organelle, but rather mitochondrial fragments containing specific cargo[7,8]. This mechanism requires the coordination of mitochondrial dynamics, mitophagy and also the vacuolar protein sorting (VPS) or retromer complex. In this process, changes in the mitochondrial membrane potential and the oxidation state of mitochondrial subcompartments induce the curvature of the membrane which is followed by recruitment of PINK1 and PARKIN [9]. The retromer complex, formed by VPS26, VPS29 and VPS35, provides the force to generate a vesicle which is then delivered to lysosomes or peroxisomes in a process which is independent of the autophagy proteins ATG5 or LC3 [10-12]. In summary, mitophagy and its variants are crucial pathways to degrade parts of the mitochondrial network, thus maintaining cellular fitness.

Many inherited forms of neurodegenerative diseases are examples for insufficient mitochondrial quality control. Mutations of specific receptors involved in targeting dysfunctional organelles to mitophagy like PINK1 and PARKIN, but also malfunction of lysosomal proteins ATP13A2 and LAMP3 among many others, as well as mutations in the retromer component *VPS35* [13] cause familial forms of Parkinson´s disease. Parkinson's disease is caused by the specific degeneration of dopaminergic neurons which have been comprehensively shown to be a hotspot for the accumulation of large scale mtDNA deletions during normal aging [14,15] making mitochondrial quality control mechanisms especially important in these cells. Unfortunately, these mechanisms are not sufficient to counteract the often progressive phenotype of patients suffering from PD and other diseases caused by either maternally inherited or by acquired mtDNA alterations, the latter due to mutations in proteins essential for mtDNA replication and

78   maintenance [16]. Thus, therapeutic approaches to increase mitochondrial quality control and
79   counteract the progression of mtDNA related diseases have been attempted [17,18], but a lack of
80   specificity and activation of undesirable effects are still a hallmark [19]. Therefore, understanding
81   the specific mechanisms governing mtDNA turnover is pivotal to develop new therapeutic
82   strategies against these syndromes.

83   Expressing the mitochondrial helicase Twinkle bearing dominant negative mutations causing
84   mitochondrial disease in patients induces mtDNA instability [20]. Expression of the disease related
85   *PEO1* Twinkle mutation K320E (from now on K320E) in mouse models accelerates the
86   accumulation of mtDNA deletions in postmitotic tissues like heart and muscle[21,22] during aging
87   and induce mtDNA depletion in proliferating cells such as epidermis and cartilage[23,24]. Recently,
88   it has been shown that muscles from those mice accumulated deletions, but the main
89   alterations were gene duplications, leading to a vast variety of different enlarged and rearranged
90   molecules [25]. Using a combination of *in vivo* and *in vitro* approaches, we have now identified the
91   proteins involved in a new mechanism for targeting and specific degradation of mtDNA to avoid
92   the accumulation of such mutations. Expression of K320E induces the formation of
93   mitochondrial extrusions, much larger than MDVs, which are consecutively engulfed by
94   autophagosomes and fused with lysosomes. Elimination of altered mtDNA molecules is
95   preceded by the relocation of nucleoids to the poles of mitochondria, a process controlled by the
96   interaction between the mitochondrial inner membrane protein ATAD3 and the nucleoid protein
97   Twinkle. The translocase protein SAMM50 and VPS35 are essential to provide the required
98   selectivity and specificity for mtDNA elimination. We show that stimulation of autophagy by
99   rapamycin *in vivo* is sufficient to specifically remove deleted mtDNA, but without affecting the
100   total mtDNA copy number. Thus, modulation of autophagy *in vivo* can be used as an approach
101   to counteract the accumulation of mutations in mtDNA observed in several mitochondrial
102   pathologies and during aging.

103

104   **RESULTS**

105

106   **Accumulation of mtDNA mutations in skeletal muscles *in vivo* does not induce**
107   **mitophagy**

108   In a previous work we have found that, in extraocular muscles, which are first affected in *Peo1*
109   patients, mtDNA alterations preferentially accumulated in fast twitch in contrast to slow oxidative
110   fibers, indicating important differences in mitochondrial quality control mechanisms in different
111   muscle fiber types [22]. To study the nature of these mechanisms surveillant mtDNA integrity, we
112   first analysed fast-twitch M. tibialis anterior (TA) and slow-oxidative M. soleus (SOL), muscles
113   both rich in fibers with a high mitochondrial content in mice, but with a preferentially glycolytic
114   (TA) vs. oxidative metabolism (SOL), respectively. As shown before by deep sequencing[25], both
115   muscles showed an accumulation of many mtDNA alterations in 24 months old animals (Fig.
116   1a). K320E mutant mice carry a wide variety of reorganized mtDNA molecules[25], causing an
117   inefficient amplification reaction leading to a smear of products, however there were no changes

118   in total mtDNA copy number (Fig. 1b). Noteworthy, TA from aged wt mice also showed many
119   mtDNA alterations, while only few were found in SOL. By conventional PCR, we analysed the
120   presence of deletions common in aged mice [22] and selected a deletion covering about 4000bp
121   (*Mus musculus* mtDNA-$\Delta^{983-4977}$), which was present in both mutant muscles (Fig. S1a).
122   Considering that mtDNA copy number is on average 20% higher in SOL than in TA (Fig. S1b),
123   we performed qPCR quantification using the D-Loop region as a reference and found that
124   indeed, this deletion was on average 20 times more abundant in TA compared to SOL (Fig. 1c).
125   Steady state levels of common mitochondrial autophagy markers showed that in SOL of
126   K320E^{skm} mice, the general autophagy adaptors p62 and LC3 were significantly decreased
127   while levels were similar in TA (Fig. 1d, e). Levels of the specific mitophagy adaptor Optineurin
128   (OPT) and the mitochondrial marker TOM20 were similar in all samples.   *In situ*
129   immunofluorescence of LC3 and p62 confirmed reduced puncta of those proteins (Fig. S1c-f).
130   Since such a reduction could reflect both an increase or a decrease of autophagy flux, we
131   blocked autophagy flux by chloroquine, and analysed the conversion of LC3-I to LC3-II (Fig. 1f,
132   g). We did not observe an increased autophagy flux in K320E mice compared to control mice.
133   However, in SOL for K320E mice, chloroquine was not inducing a change in the LC3 ratio
134   suggesting that, in this muscle, autophagy flux was already at maximum level in steady state.
135   We therefore hypothesized that oxidative fibres, which are most dependent on intact
136   mitochondria, possess a faster mitochondrial turnover, hence maintaining mutated mtDNA
137   molecules more efficiently below a pathogenic threshold. To visualize protein synthesis *in vivo*,
138   we fed our mice with heavy lysine ($^{13}C_6$-lysine) for two weeks in order to get an estimate for
139   mitochondrial turnover rates [26]. Here, we selected SOL and M. extensor digitorum longus (EDL)
140   for analysis, since the latter contains almost exclusively glycolytic fibers. We first confirmed that
141   heavy Lysine incorporation was equal in all animals (Fig. S2a, b). We analysed H/L (heavy/light)
142   ratios of detected proteins (1286 and 1224 for SOL, 1042 and 1018 for EDL in wild-type and
143   K320E^{skm} mice, respectively) and filtered the mitochondrial proteins using Mitocarta 3.0
144   (Supplementary Table 1; Fig. S1c). Surprisingly, no mitochondrial protein was showing
145   differential incorporation of heavy lysine comparing K320E mutant and wild-type animals,
146   neither in EDL nor in SOL, suggesting that bulk mitochondrial turnover, here measured as an
147   increase of mitochondrial biogenesis, is not enhanced in muscles bearing mtDNA alterations
148   (Fig. 1h).
149
150   **Autophagy is required for depletion of mtDNA following oxidative damage**
151   To further dissect the molecular pathways activated upon mtDNA instability, we generated
152   stable C2C12 myoblast cell lines expressing tagged versions of Twinkle and K320E.
153   Colocalization of these variants with mitochondria (outer membrane marker TOM20, Fig. S3a,
154   b) as well as colocalization with mtDNA and the mtDNA binding protein TFAM was confirmed
155   (Fig. S3c, d), showing that Twinkle is enriched in mitochondrial nucleoids.
156   To investigate if K320E expression leads to activation of autophagy or mitophagy in these cells,
157   C2C12 myoblasts were additionally transfected with plasmids encoding LC3-GFP-mCherry or

158　　Fis1p-GFP-mCherry. Expression of K320E induced the accumulation of autolysosomes marked

159　　by LC3-GFP-mCherry (Fig. 2a, b; magenta signal). In agreement with our *in vivo* pSILAC

160　　results, expression of Fis1p-GFP-mCherry, a mitophagy reporter, showed no activation of acute

161　　mitophagy (Fig. 2c, d). Previous studies have demonstrated that the *in vitro* expression of

162　　several Twinkle missense mutations often leads to accumulation of mtDNA replication

163　　intermediates, producing mtDNA depletion [27]. Consistently, expression of K320E leads to

164　　mtDNA depletion (Fig. 2e), but this was not related to a decrease in mtDNA replication rate, as

165　　observed by analysis of mtDNA replication foci in BrdU labelled cells (Fig. S4a, b). We

166　　hypothesized that accumulation of lysosomes and mtDNA depletion after expressing K320E

167　　was reflecting a novel selective mtDNA degradation process. Thus, we blocked lysosomal

168　　activity using chloroquine and showed that, indeed, under these conditions, mtDNA levels

169　　remained at control levels (Fig. 2f). Finally, we analysed the spatial relationship between

170　　Twinkle foci and autophagy structures, using LC3 as an autophagosome marker and Lamp1 as

171　　a late endosomal marker, respectively. As expected, most wt Twinkle foci distributed in a

172　　pattern reflecting the mitochondrial network and were independent of autophagy markers (Fig.

173　　2g-j). However, colocalization with LC3 and LAMP1, respectively, was observed with K320E.

174　　The increased mtDNA degradation flux in K320E cells suggests that expression of this

175　　missense mutation harms mtDNA by unknown means. To visualize *in situ* mtDNA damage, we

176　　searched for the presence of 8-hydroxy-2′deoxyguanosine (8-OHdG), a specific base

177　　modification induced by reactive oxygen species [28]. We could not observe any specific staining

178　　with α-8-OHdG in steady state levels (Fig. S4c, d), however when cells were incubated in

179　　presence of chloroquine, we detected a specific accumulation of 8-OHdG decorating the

180　　mitochondrial network only in K320E expressing cells (Fig. 2k, l). In summary, our data indicate

181　　that K320E induces mtDNA depletion in a lysosome-dependent manner without involving acute

182　　mitophagy, pointing to a more specialized path.

183　　To further analyse the contribution of autophagy to mtDNA turnover, we turned to Atg5 KO

184　　MEFs and expressed Twinkle variants (Fig. 3a), since Atg5 has been shown to be important in

185　　quality control after mitochondrial damage [29]. Analysis of mitochondrial nucleoids showed that

186　　K320E expression decreased nucleoid foci number in Atg5 wt cells (Fig. 3b). In contrast, in Atg5

187　　KO cells, foci number was not altered by K320E expression (Fig. 3c). Nevertheless, expression

188　　of K320E reduced mtDNA copy number in both Atg5 WT and Atg5 KO cells (Fig. 3d, e).

189　　Analysis of mtDNA replication by BrdU labelling showed that, in contrast to wt cells, expression

190　　of K320E in autophagy deficient cells led to a reduced number of foci replicating mtDNA within

191　　the mitochondrial network (Fig. 3f, g). Chloroquine treatment also restored mtDNA copy number

192　　in Atg5 WT cells expressing K320E but not in Atg5 KO cells (Fig. 3h). Our data suggest that in

193　　contrast to wt cells where K320E induces mtDNA depletion linked to an increased nucleoid

194　　turnover rate, in autophagy deficient cells, mtDNA depletion is caused by reduced mtDNA

195　　replication, presumably to avoid accumulation of excessive mtDNA damage.

196　　Therefore, to evaluate the role of autophagy in mtDNA depletion, we induced mtDNA alterations

197　　by growing these cells for 7 days in medium containing Ethidium Bromide (EtBr), which we also

198 found to provoke the accumulation of 8-OHdG within the mitochondrial network (Fig. S4c, e).

199 Morphological analysis of mitochondrial nucleoids showed that EtBr decreases foci number in

200 Atg5 WT cells but not in Atg5 KO (Fig. 3i-k). In line with this, Atg5 control cells showed

201 consistent mtDNA depletion, whereas in Atg5 KO cells mtDNA copy number remained

202 unchanged (Fig. 3l). This EtBr-induced depletion could not be recovered by overexpression of

203 wt Twinkle, indicating again a prominent role of autophagy in mtDNA depletion in this case.

204 All these data together confirm that mtDNA damage induces activation of a mtDNA turnover

205 mechanism, which is dependent on autophagosome formation and specifically degrades

206 mtDNA but it does not activate an acute mitophagy response.

207

208 mtDNA instability induces the formation of mitochondrial protrusions prior to lysosomal

209 degradation

210 One of the most surprising features we noticed while studying cellular localization of Twinkle

211 was that TOM20, a mitochondrial outer membrane marker, does not consistently overlap with

212 Twinkle, a mitochondrial matrix protein (Fig. 4a and S3a, b). Live imaging microscopy using

213 C2C12 clones expressing Twinkle-mCherry showed that occasionally, Twinkle moved to

214 Mitotracker Green-negative poles of the network releasing a small particle which was also

215 Mitotracker-negative (Fig. 4b, arrows). These particles were more evident in K320E expressing

216 cells, where most of K320E was residing in such Mitotracker-negative structures (Fig. 4c). As

217 Mitotracker green is independent of the inner membrane potential, we ruled out the possibility

218 that these regions were depolarized areas of the mitochondrial network but mitochondrial

219 regions with different cardiolipin composition.

220 To determine Twinkle localisation with high resolution, we used Twinkle-APEX2 fusion versions

221 in C2C12 cell lines. APEX2 generates a black precipitate in the presence of DAB, which is

222 visible by electron microscopy. Twinkle-APEX2 distribution in the matrix was heterogeneous

223 and the organization of mitochondria and other cellular organelles was undisturbed by its

224 expression (Fig. 4d). K320E-APEX2, however, accumulated in poles of the network, sometimes

225 close to abnormal cristae structures (Fig. 3d, red arrows) and also inside lysosomes (Fig. 4d,

226 red stars). Such multi-membrane structures were also observed in cells expressing a

227 mitochondrial matrix targeted APEX2, but in that case, they did not show DAB precipitate (Fig.

228 4d, red stars). A very recent study demonstrated that mitochondrial fission occurring at

229 mitochondrial poles is followed by mitophagy of mitochondrial compartments containing non-

230 replicative mtDNA, and that this is preceded by mitochondrial cristae reorganization [30]. Indeed,

231 electron tomography of K320E expressing cells revealed that these structures are derived from

232 the inner mitochondrial membrane and that they are formed by protrusions containing

233 reorganized mitochondrial cristae (Fig. 4e).

234

235 Twinkle interacts with membrane proteins to facilitate mtDNA removal

236 We speculated that mtDNA targeting prior to degradation is controlled by specific protein-protein

237 interactions. Thus, as Twinkle follows mtDNA positioning and degradation through lysosomes,

238   we sought to investigate how nucleoids containing Twinkle distribute in the mitochondrial matrix

239   by analysing the Twinkle interactome. We performed immunoprecipitation of wt Twinkle fused to

240   a V5-APEX2 epitope followed by mass spectrometry analysis. As expected, the majority of

241   proteins interacting with Twinkle were related to mtDNA replication, transcription and translation

242   (Supplementary Table 2), but only a few interactions were found to be significant (Fig. 5a, blue

243   dots), one of them being ATAD3, an AAA-ATPase previously linked to anchoring and

244   distribution of mtDNA to the inner membrane [31]. Direct co-immunoprecipitation and

245   immunofluorescence confirmed the physical interaction between ATAD3 and Twinkle (Fig. 5b;

246   Fig. S5a) enlightening Twinkle as an important part of the link between mitochondrial nucleoids

247   and the inner membrane.

248   To evaluate the role of these proteins in mtDNA turnover, we generated constitutive *Atad3*

249   knock-down (KD) clones (shAtad3_1+2, shAtad3_3; Fig. S5b, c). *Atad3* KD clones showed

250   steady state levels of mtDNA copy number comparable to control lines (Fig. 5c, d) and no

251   changes in mitochondrial morphology (Fig. S5d). After one week of mild treatment with EtBr,

252   control cells showed a persistent decrease of mtDNA copy number. However, this depletion

253   was not observed in Atad3 KD clones (Fig. 5d). Number of nucleoid foci per cell was also higher

254   in downregulated clones than in control cells upon EtBr treatment (Fig. 5e). These data suggest

255   that nucleoid binding to the mitochondrial inner membrane through a Twinkle-ATAD3 interaction

256   is essential for mtDNA elimination upon mtDNA damage.

257

258   **mtDNA turnover requires coordination of the retromer complex in a process independent**

259   **of MDVs**

260   We initially hypothesized that selective removal of mitochondrial fragments containing mtDNA

261   was carried out through MDVs [7]. The E3 Ubiquitin ligase MAPL has been shown to direct

262   mitochondrial cargo to peroxisomes [32], while the endosomal adaptor Tollip specifically divert

263   MDVs to lysosomes [8]. In both cases, the VPS35-retromer complex initiates the force to

264   generate a vesicle [10]. Thus, in order to investigate if the specific mtDNA degradation we

265   observed follows the MDV or a new pathway, we studied VPS35 and MAPL localization in

266   Twinkle-mCherry expressing cells. Consistent with previous studies, expression of MAPL-GFP

267   induced mitochondrial fission and formation of structures excluding TOM20 (Fig. S6a) [32].

268   However, Twinkle was also excluded from those particles. Chloroquine treatment for 4h was

269   sufficient to induce a rapid accumulation of Twinkle positive structures excluding TOM20 and

270   MAPL, suggesting that the fate of those particles is the lysosomal compartment (Fig. S5b). In

271   addition, we also corroborate that Twinkle colocalizes with VPS35 but excludes MAPL (Fig.

272   S6c, d).

273   Next, we treated these cells as well with EtBr to induce mtDNA damage. One week of treatment

274   was sufficient to reduce mtDNA copy number (Fig. S7a). Image quantification revealed that the

275   percentage of VPS35 containing Twinkle was strongly increased upon EtBr treatment (Fig. 6a-

276   c), even when the overall steady state levels of VPS35 structures did not change (Fig. 6d).

277   Importantly, VPS35 also colocalized with dsDNA (Fig. 6e).

278   We then generated Vps35 KO clones in MEFs and selected two monoclonal lines targeting

279   exon 4 (*Vps35*_Ex4) and exon 5 (*Vps35*_Ex5) (Fig. S6b, c). Vps35 KO cells showed no

280   changes in mtDNA foci number but reduced levels of mtDNA copy number in steady state (Fig.

281   6f-h) and mitochondrial fragmentation (Fig. S7d). After 7 days of EtBr treatment, the number of

282   mtDNA foci was further decreased (Fig. S7e, f) and mtDNA depletion was enhanced (Fig. S7g,

283   h). We analysed the activation of canonical mitophagy in steady state by expressing Fis1p-

284   GFP-mCherry (Fig. 6i) and found that, indeed, in Vps35 KO cells, acute mitophagy was

285   activated (Fig. 6j). Moreover, VPS35 protein level was shown to be affected by lysosomal

286   function, as chloroquine induced VPS35 accumulation in K320E cells (Fig. S7i, j) without

287   interfering with late endosomes or mitochondrial content (Fig. S7i-n).

288   We hypothesize that VPS35 is necessary to fine-tune the elimination of mutated mtDNA without

289   activating acute mitophagy and sought to investigate how VPS35 is recruited to mitochondria

290   upon mtDNA damage. Thus, we performed VPS35 IP followed by MS analysis under basal

291   conditions and in cells treated 7 days with EtBr (Fig. S8a). As expected, in basal medium the

292   protein profile of VPS35 IP revealed poor interaction with mitochondrial proteins (Fig. 7a, red

293   dots). Upon EtBr treatment, however, the association of mitochondrial proteins was markedly

294   increased (Fig. 7b, c). Among them, we noticed the presence of mitochondrial membrane

295   proteins such as VDAC1 and VDAC3, TIMMDC1 or TOMM40 as well as SAMM50, which

296   interaction was confirmed by coimmunoprecipitation (Fig. 7d). The comparison of IP protein

297   profiles of cells in basal vs. EtBr medium highlighted also a strong enrichment of the mAAA

298   protease SPG7 (Fig. S8b). Remarkably, comparison between the IP protein profiles from

299   Twinkle and K320E revealed also a strong enrichment of SAMM50 upon K320E

300   immunoprecipitation (Fig. 7e). SAMM50 belongs to the sorting and assembly machinery in the

301   mitochondrial intermembrane space and has important functions in the biogenesis of respiratory

302   complexes, cristae morphology and mitochondrial shape [33]. It was also described as a regulator

303   of PINK1-Parkin mediated mitophagy but excluding the mtDNA for degradation [34].

304   Immunoprecipitation of Twinkle confirms that, after mtDNA damage with EtBr, Twinkle can

305   physically interact with SAMM50 (Fig. 7f).

306   Thus, we hypothesize that SAMM50, a protein located in the mitochondrial outer membrane,

307   could serve as a platform to recruit VPS35 and eliminate mitochondrial subcompartments

308   containing damaged mtDNA. Consequently, we generated SAMM50 shRNA KD clones and

309   expressed Twinkle-mCherry (Fig. 7g; Fig. S8c, d). EtBr does not affect the overall population of

310   VPS35 but enhances recruitment to Twinkle (Fig. 7g-i). However, the percentage of VPS35-

311   Twinkle contacts were reduced in absence of SAMM50 (Fig. 7i). To decipher if VPS35

312   recruitment shows Twinkle specificity, we examined VPS35 colocalization with LRPPRC, a

313   native mitochondrial matrix protein (Fig. S8e). Again, the overall number of VPS35 particles

314   was unchanged by EtBr treatment (Fig. S8f) and in this case, we observed that VPS35 contacts

315   with LRPPRC were not increased and therefore, there was no effect following Samm50

316   downregulation (Fig. S8g).

317 In summary, our data thus demonstrate that VPS35 is required for mitochondrial quality control
318 in the presence of mtDNA alterations. We show that a mechanism to specifically remove
319 mtDNA is activated when mtDNA damage is induced both genetically or chemically by K320E or
320 by EtBr, respectively. ATAD3 is required for specific membrane localization of nucleoids,
321 SAMM50 confers nucleoid specificity and VPS35 is involved in fine-tuning of this selective
322 process, removing specific parts of mitochondria containing affected nucleoids, thus avoiding
323 the activation of acute mitophagy which would affect the functional mitochondrial pool.

324
325 **Rapamycin eliminates mtDNA alterations without affecting copy number**
326 Since our data highlight that autophagy, together with a specific nucleoid extraction mechanism,
327 plays an important role in maintaining mtDNA fitness *in vitro*, we aimed to test whether this is
328 also relevant *in vivo*. We have previously shown that expression of K320E in skeletal muscle
329 leads to the accumulation of mtDNA alterations, unfortunately only in very old animals, making
330 this model not very convenient [22] (Fig. 1). However, expression of K320E in muscle satellite
331 cells (Pax7-Cre[ERT]; K320E[msc]), followed by cardiotoxin-induced muscle damage and one week
332 of regeneration, shows a rapid accumulation of mtDNA alterations, leading to newly generated,
333 cytochrome-c-oxidase (COX) negative fibers (stained blue, Fig. S8a, b), while mtDNA copy
334 number remained stable (Fig. S8c). In several mitochondrial disease models, it has been shown
335 that rapamycin, an activator of autophagy through the specific inhibition of mTORC1, is able to
336 revert mitochondrial dysfunction and ameliorate disease progression. This probably occurs by
337 stimulating mitochondrial turnover mechanisms [35], and, *in vitro* it was also shown to direct
338 selection against mtDNA mutations [36]. Interestingly, genetic induction of autophagy was shown
339 to reduce mtDNA deletions in *Drosophila* [37]. Thus, to test if activation of autophagy can purify
340 mtDNA alterations also in mammals *in vivo*, we used this muscle regeneration paradigm in
341 combination with rapamycin treatment. Regenerated muscles from vehicle treated K320E[msc]
342 mice showed a prominent accumulation of COX negative fibers indicating mitochondrial
343 dysfunction (Fig. 8a). In contrast, mice treated with rapamycin showed much less COX deficient
344 cells in the regenerated area (Fig. 8a-c). Consistently, qPCR analysis revealed that mtDNA
345 copy number remained unchanged (Fig. 8d), while mtDNA alterations were absent and thus had
346 been purified (Fig. 8e). We noticed that COX staining was much lighter in rapamycin treated
347 animals, suggesting a change in mitochondrial OXPHOS activity. Vehicle treated mice showed
348 a predominant accumulation of glycolytic fiber type 2b in both wt and K320E[msc] mice (Fig. S9d),
349 while in rapamycin treated wt mice, fiber type staining showed a predominant shift towards
350 mitochondria rich type I fibers (Fig. S9e). Interestingly, in K320E[msc] mice regenerated fibers
351 showed a mixed myosin heavy chain pattern after one week of regeneration. These data
352 indicate that rapamycin can be used as a modulator of mitochondrial turnover which specifically
353 purifies mutated mtDNA species, thus ameliorating mitochondrial dysfunction, albeit changing
354 muscle fiber type composition.

355
356 **Discussion**

357 Autophagy and specifically mitophagy and its variants are well-established pathways for
358 mitochondrial turnover, which is essential to maintain mitochondrial fitness [4]. Loss of
359 mitochondrial quality control mechanisms, either by specific mutations of key players or by
360 reduced autophagy activity, strikingly correlates with the acquirement of mtDNA mutations [38].
361 However, an exacerbated activation of mitophagy may lead to a serious reduction of the
362 mitochondrial pool, thus affecting cellular energy supply [39]. Therefore, the fine-tuned regulation
363 of mitochondrial quality control mechanisms is essential to maintain cellular energy
364 homeostasis.

365 Although toxic substances can cause mitochondrial damage, the most prevalent reason is the
366 accumulation of alterations in mtDNA due to replication errors. Mutations in genes encoding
367 proteins involved in mtDNA replication, like the helicase Twinkle, and in mtDNA maintenance
368 cause mutations leading to mitochondrial diseases, with brain and skeletal muscle being
369 regularly affected. In addition, somatic mutations in mtDNA accumulate during the normal aging
370 process in many organs in humans [3], leading to a tissue mosaic where few cells with
371 mitochondrial dysfunction, caused by high mutation loads, are embedded in normal tissue [40].

372 In general, tissues most depending on mitochondrial function are most severely affected when
373 carrying mtDNA mutations. Paradoxically, we found that expression of the dominant negative
374 K320E mutation of Twinkle in extraocular muscle shows a remarkable differential vulnerability of
375 muscle fiber types, with mitochondrial dysfunction especially affecting fibers with a glycolytic
376 metabolism [22]. In agreement with these results, we found less mtDNA alterations in aged SOL,
377 a muscle rich in type I fibers which mostly rely on mitochondrial ATP production, compared to
378 the TA mostly composed of fast twitch, glycolytic fibers (Fig. 1). Noteworthy, different muscles
379 rich in oxidative vs. glycolytic fibers show notable differences in the expression of genes
380 involved in mitochondrial dynamics [41], making oxidative muscles more resistant to ageing
381 related dysfunction [42]. In fact, our data shows that SOL expressing K320E already has an
382 increased flux in steady state but this was not related to increased mitochondrial turnover.
383 Nevertheless, mitophagy, understood as the specific removal of the entire damaged organelle,
384 does not provide the required selectivity to remove only mutated mtDNA. Hence, the existence
385 of a specific turnover mechanism has been postulated, but not been proven yet [43].

386 In contrast to terminally differentiated muscle of aged mice, proliferating cells in culture did not
387 accumulate mtDNA alterations upon expression of K320E, instead this led to mtDNA depletion.
388 Both K320E expression or mild treatment with EtBr induced the accumulation of mtDNA
389 damage. EtBr intercalates between base pairs and slows down mtDNA replication. It is
390 accepted that EtBr, when used at low concentration, also induces frame shift mutations and
391 deletions[44] and we demonstrated that it also triggers oxidative damage in the mtDNA. Our data
392 show that mtDNA depletion induced by damage is caused by a specific exacerbated mtDNA
393 turnover which is Atg5 dependent and thus requires autophagosome formation and lysosomal
394 degradation.

395 Interestingly, K320E localizes preferentially in specific mitochondrial regions. K320E
396 localization does not overlap completely with the mitochondrial outer membrane protein TOM20

397   and is present in areas that are also not stained by Mitotracker Green, demonstrating that

398   nucleoids containing Twinkle can be specifically localized in a unique mitochondrial

399   subcompartment. Indeed, mtDNA has been shown to attach preferentially to cholesterol-rich

400   membrane structures and Twinkle, as a nucleoid protein, has been found to be enriched in

401   these areas as well [45]. The onion-like structures we observed in our cell model have been

402   detected in the muscle of patients with mitochondrial myopathy caused by mtDNA mutations [46]

403   and very recently also in ρ0-cells lacking mtDNA [47]. Here we show that mtDNA damage induces

404   cristae remodelling in poles of the mitochondrial network and that these structures containing

405   Twinkle are delivered to lysosomal compartments, which are therefore specifically involved in

406   mtDNA removal.

407   Three proteins present in three mitochondrial compartments are responsible for mtDNA

408   distribution and selective turnover: Twinkle, in the mitochondrial matrix; ATAD3, in the

409   mitochondrial inner membrane and SAMM50, in the mitochondrial outer membrane. Twinkle

410   arises as the link between nucleoids and the inner membrane through interaction with ATAD3, a

411   protein controlling several aspects of mitochondrial membrane dynamics [48]. Interestingly, the

412   human ortholog ATAD3B has been recently found to be a mitophagy receptor for mtDNA

413   damage induced by oxidative stress [49]. In the other side, SAMM50, which resides in the

414   mitochondrial outer membrane, interacts with the MICOS complex, and organizes membrane

415   architecture [50]. Interestingly, both ATAD3 and SAMM50 have been described as regulators of

416   Pink1-Parkin as well [34,51], thus providing the link between nucleoid localization and specific

417   degradation of mtDNA.

418   Furthermore, we show that upon mtDNA damage, VPS35, an endosomal protein involved in

419   mitochondrial quality control, increases contacts to mitochondrial subcompartments containing

420   Twinkle. Interestingly, VPS35 deficient cells showed a persistent activation of mitophagy with

421   mtDNA depletion. The fact that *Samm50* depletion induces mitophagy, but excludes mtDNA

422   degradation [34], suggests that SAMM50 confers the required selectivity and VPS35 the

423   specificity to remove only fragments containing mtDNA.

424   Removal of mitochondrial fragments has been shown to take part through a specialized

425   pathway called Mitochondrial Derived Vesicles (MDVs) [7]. Currently, only a few proteins have

426   been found to determine cargo and vesicle fate. While MAPL generates vesicles which divert

427   oxidized cargo to peroxisomes [32], Tollip, an endosomal organizer, synchronizes Parkin-

428   dependent MDVs directed to the lysosomal compartment [8]. Canonical MDVs are generated in

429   the mitochondria in an Atg5 and LC3 independent manner [32], however, mtDNA damage by

430   K320E expression showed accumulation of LC3 autophagosomes and mtDNA depletion which

431   is Atg5 dependent. Additionally, electron microscopic pictures of our cells never showed

432   vesicles resembling MDVs, which are much smaller than the mitochondrial extrusions and

433   autolysosomes containing Twinkle we observed. Furthermore, we unequivocally showed that

434   Twinkle particles are directed to the lysosomal compartment and that VPS35 associates with

435   mitochondria upon mtDNA damage. We also showed that VPS35 recruitment is SAMM50

436   dependent and, upon mtDNA damage, such recruitment is specific to Twinkle containing

437   regions. Upon EtBr damage, we confirmed that VPS35 precipitates with mitochondrial outer
438   membrane proteins, such as SAMM50, TOMM40, TIMMDC1 and VDAC1 and VDAC3 and it is
439   in this environment when Twinkle, a mitochondrial matrix protein, interacts with SAMM50.
440   mtDNA removal exemplifies a specialized mitophagy trail. Delivery of specific mitochondrial
441   cargo to quality control pathways through VPS35 was previously shown to be highly regulated.
442   If the selected cargo is diverted into peroxisomes, VPS35 associates with MDVs by interacting
443   with MAPL in a Drp1 independent manner [10]. However, if the MDVs are directed to lysosomes
444   the association is dependent on Drp1 [52]. On the other hand, SAMM50 modifies mitochondrial
445   structure by interacting with Drp1 [53] and with the Pink1-Parkin machinery for selective
446   mitophagy [34]. Hence, SAMM50 works as a platform where mitochondrial fission, membrane
447   architecture, and mitophagy components orchestrate membrane protrusions and facilitate
448   VPS35 recruitment. Very recently, SAMM50 has been linked also to piecemeal mitophagy,
449   independent of MDVs, through direct interaction with the p62 adaptor [54]. Hence, we conclude
450   that specific mtDNA degradation does not follow the MDV pathway, despite the fact that they
451   share some components, and that it is more likely that mitochondrial protrusions containing
452   nucleoids are engulfed in autophagosomes in a specialized mitophagy pathway.
453   VPS35, which has been extensively linked to neurological diseases such as Parkinson's and
454   Alzheimer disease, appears as a regulator of mtDNA quality control necessary to maintain
455   mitochondrial intactness. Modulation of *VPS35* expression has been evaluated as a potential
456   approach against Parkinson's disease [55] and, in *Drosophila*, *Vps35* overexpression can rescue
457   an LRRK2-induced Parkinson´s phenotype [56]. iPSC derived neurons from *LRKK2*-PD patients
458   showed accumulation of mtDNA damage [57]. Nonetheless, the ability of VPS35 to eliminate such
459   molecules in a human disease related model needs to be further explored as a potential
460   therapeutic strategy.
461   Enrichment of Spg7 upon VPS35 IP in EtBr treated cells also suggests the involvement of
462   mitochondrial proteases. Mitochondrial matrix proteases (mAAAs) represent a group of
463   enzymes related to mitochondrial quality control and mitochondrial membrane remodeling upon
464   proteolytic cleavage of Opa1 and Oma1. Spg7 has been found to copurify with Prohibitin
465   participating in the formation of the permeability transition pore [58,59]. Mutations in the *SPG7*
466   gene are the cause for Hereditary Spastic Paraplegia Type 7 but also a Progressive External
467   Optalmoplegia-like syndrome with accumulation of mtDNA deletions [60]. Hence, it is tempting to
468   propose that Spg7 works as a regulator of mtDNA turnover as well. However, further studies are
469   needed to reveal its specific role and regulation of the process.
470   Finally, our data demonstrate that specific removal of mtDNA is linked to lysosomal activity.
471   Lysosomal degradation of bulk autophagy is regulated by the serine-threonine protein kinase
472   mTORC1 which resides on the lysosomal surface. mtDNA replication defects activate mTORC1
473   and the integrated mitochondrial stress response in a cascade of effects with wide downstream
474   consequences [61]. It is well known that mTORC1 activation inhibits autophagy by influencing
475   both the formation of autophagosomes but also lysosomal acidification [62]. In order to prove the
476   selectivity of this process *in vivo*, we used a mouse model where mtDNA alterations rapidly

477 accumulate and indeed, activation of the mTORC1 pathway by rapamycin was able to eliminate
478 abnormal mtDNA molecules and thus reduces the accumulation of cells with mitochondrial
479 dysfunction. Rapamycin has been described as a potential treatment against mitochondrial
480 diseases [18,63], however, since we observed a fiber-type shift, mTORC1 inhibition might activate
481 other signalling pathways with undesirable effects. Nonetheless, by using Rapamycin we
482 demonstrated that elimination of mutant mtDNA without affecting total mtDNA copy number is
483 possible.
484 In conclusion, we unveil a new complex mechanism with physiological relevance for
485 mitochondrial fitness. Twinkle mediates nucleoid binding to the mitochondrial inner membrane
486 through ATAD3 interaction, which is responsible for nucleoid organization. SAMM50 provides
487 the required specificity to eliminate mtDNA while VPS35 supplies the selectivity. Interestingly,
488 mutations in *TWNK*, *ATAD3A* and *VPS35* have been linked to several severe mitochondrial
489 diseases having in common mtDNA instability [64-66], therefore representing a cluster of proteins
490 involved in specific mtDNA turnover. Fine tuning the activity of such proteins could be used as a
491 therapeutic strategy against mtDNA related diseases, either inherited, acquired or due to normal
492 ageing.
493
494 **Methods**
495
496 ***In vivo* experimental approaches**
497 K320E transgenic mice were generated by crossing R26-K320EloxP/+ mice (point mutation
498 K320E; Rosa26-Stop-construct; downstream EGFP) with mice expressing Cre recombinase
499 under the control of the skeletal muscle-specific MLC1f- promoter or satellite cells Pax7-Cre[ERT].
500 All mice used for experiments were housed in a standard animal facility maintained at 23°C,
501 12:12h light-dark cycle, with free access to water and standard rodent chow. Autophagy flux
502 was tested by intraperitoneal injection of 50mg/kg chloroquine 4h prior euthanasia. All
503 procedures and experimentation with mice were performed according to protocols approved by
504 the local authority (LANUV, Landesamt für Natur, Umwelt und Verbraucherschutz NRW,
505 approval number: 2019-A090). Activation of Pax7-Cre[ERT] promotor was performed by injecting
506 daily, for 5 days, intraperitoneal 2mg tamoxifen dissolved in mygliol. For muscle regeneration
507 experiments, 2 days after the last tamoxifen injection, mice were anesthetized with 2%Xylazin,
508 10% Ketamine in NaCl 0.9% and 10µM Cardiotoxin (*Naja Pallida*, Latoxan) was injected inside
509 the fascia. After 2 days of rest, 2mg/kg rapamycin dissolved in mygliol was injected
510 intraperitoneally daily for 5 days. The day after the last injection, mice were treated as explained
511 below.
512
513 **Molecular biology and vector generation**
514 *Twnk* ORF was amplified from plasmids pJet2-Twinkle and pROSA-K320E [67] and cloned in
515 pmCherry-N1. For retroviral vector generation, Twinkle and Twinkle-mCherry, ORF was
516 amplified and subcloned into pLenti-CMV Puro DEST (Addgene #17452). All ORFs were

517 subcloned into pBabe-Puro vector, kindly provided by Dr. Bernhard Schermer, and verified by

518 Sanger sequencing. pLX304-TWINKLE-APEX2 vector was kindly provided by Dr. Alice Ting. To

519 generate *Mus musculus Twnk* vectors, *Homo sapines TWNK* was replaced by *Twnk* ORF and

520 subcloned into pBABE-Puro vector. Mitochondrial matrix APEX2 control vector (Addgene

521 #72480) was also subcloned into pBABE-Puro. For generation of Tfam-GFP, total RNA from

522 mouse liver was isolated and converted into cDNA using TRIzol (Thermo Fisher) and RevertAid

523 First Strand cDNA Synthesis Kit (Thermo Fisher) using PolyT as feeder. *Tfam* cDNA was

524 cloned into pEGFP-N1. Atad3 KD and Samm50 KD clones were generated by transducing

525 MEFs with the vector pMKO1-GFP (Addgene #10676) containing a shRNA (Table M1). Empty

526 vector and a scramble containing vector were used as a control. For CRISPR Cas9 KO

527 generation two gRNA directed to exon 4 and exon 5 (Table M1) were cloned in pSpCas9 (BB)-

528 2A-Puro V2.0 (Addgene #62988).

529

Generation and culture of cell lines

531 C2C12 cell line was purchased from ATTC and grown in DMEM 4.5 g/L Glucose + GlutaMax,

532 20% FBS, 1x Pen/Strep. Immortalized mouse embryonic fibroblast Atg5WT and Atg5KO MEFs

533 [68] and immortalized MEFs line were maintained as described [69]. Stable cell lines were

534 generated by transducing C2C12 cells or MEFs with pBABE-Puro retroviruses. Briefly, $2.5x10^6$

535 HEK293 cells were plated in $10cm^2$ dish transfected with pCL-ECO (5 µg) and pBABE-Puro (10

536 µg) vectors using PEI (40 µl). After 48h and 72h, medium containing viruses was harvested,

537 filtered through 45 µm, mixed with 8µg/ml Polybrene and added to 250.000 cells previously

538 plated. 48h post transduction, positive clones were selected by adding Puromycin 2.5 µg/ml to

539 the medium in C2C12 and 5µg/ml to MEFs, which was maintained during all the experiments.

540 shRNA clones were generated by transducing MEFs with pMKO.1-GFP vectors. Prior to all

541 experiments, transduction rate was verified to be higher than 99% of GFP expressing cells by

542 Flow cytometry. For generation of Vps35 CRISPR Cas9 KO clones, MEFs were transiently

543 transfected with the vector containing gRNA and selected with 3 µg/ml puromycin for 4 days.

544 Single clones were plated independently using cloning cylinders, analyzed by western blotting.

545 Genomic DNA was isolated from VPS35-negative cells and genomic DNA modification was

546 verified by Sanger sequencing. Exon 4 and Exon 5 were amplified (Table M1) and cloned using

547 pJET1.2 cloning kit (Thermo Fisher) before sequencing.

548 Transient transfection was achieved transfecting the corresponding plasmids using

549 Lipofectamine 3000 following manufacturer instructions. Plasmids use in this work were: LC3-

550 GFP (Addgene #21073), Lamp1-GFP (Addgene #34831), Fis1p-Cherry-GFP [70], LC3-Fis1p-

551 Cherry (kindly provided by Dr. Terje Johansen) and MAPL-GFP from CECAD Imaging Facility

552 [32].

553 For mtDNA depletion experiments, cells were maintained as described before for 7 days but

554 media was supplemented with 50 ng/ml Ethidium and 50 µg/ml Uridine. Lysosomal function was

555 blocked using 10 µM Chloroquine for 24h.

556

557 **mtDNA amplification**

558 Total DNA was isolated using DNeasy Blood & Tissue Kit (Qiagen) according to manufacturer´s

559 instruction. 25 ng of total DNA was used for analysis of threshold amplification differences

560 between mtDNA and nuclear DNA (delta C(t) method with specific primers (Table M1). Long

561 range PCR was used to screen for the presence of mtDNA alterations. 14 Kb of mtDNA was

562 amplified using Rabbit Bioscience Long Range kit with oligos described in table M1.

563

564 **Western blot and co-immunoprecipitation**

565 Cells pellets were lysed with RIPA-buffer (150 mM NaCl, 1% Triton-X1000, 0.1% SDS, 50 mM

566 Tris-HCl pH 8, 0.5% Na-deoxycholate) containing protease inhibitor (Roche) and protein

567 concentration measured using the Bradford assay. Proteins were transferred after

568 electrophoresis to a PVDF-membrane previously activated with methanol. Membranes were

569 blocked (5% milk in TBS-0.1% Tween-20) and incubated overnight with primary antibodies.

570 Antibodies used in this work are: monoclonal α-V5 (Abcam), polyclonal α-V5 (Thermo

571 Scientific), polyclonal α-TOM20 and monoclonal α-VPS35 (Santa Cruz), monoclonal and

572 polyclonal α-SAMM50 (Abnova and Abcam respectively), polyclonal α-ATAD3, polyclonal α-LC3

573 and polyclonal α-p62 (Proteintech), polyclonal GAPDH (Novus Biologicals). Secondary goat

574 anti-mouse, goat anti-rabbit and goat anti-chicken HRP (Jackson Laboratory). Images were

575 acquired using the ECL Advanced Chemiluminescence kit (GE Healthcare Life Sciences ®, UK)

576 according to manufacturer's protocols and visualized using a LAS500 CCD camera.

577 For immunoprecipitation, cells expressing Twinkle-APEX2-V5 were pelleted and solubilized in

578 IP Buffer (500 mM HEPES KOH pH 7.2, 150 mM NaCl, 1 mM MgCl$_2$, 1% Triton-X1000 and

579 Protease inhibitor (Roche). 500 μg of total protein extract were used to IP with either 2.5 μg V5

580 rabbit polyclonal antibody or VPS35 mouse monoclonal over night at 4°C and recovered after

581 incubating for 6h at 4°C in a rotator with equilibrated Agarose Protein-G beads (Abcam).

582 Immunoprecipitation followed by MS analysis was performed as described but using magnetic

583 Protein G beads (Thermo Scientific). Samples were washed 5 times with washing buffer

584 (10 mM HEPES KOH pH 7.2, 150 mM NaCl, 1 mM MgCl$_2$, 0.2% Triton-X1000) and once with

585 PBS. Prior to analysis by MS, samples were washed 3x with ammonium-bicarbonate (ABC)

586 buffer, denatured with 50 μl of urea buffer (6 M urea, 2 M thiourea) and followed by disulfide-

587 bridge reduction using dithiothreitol (DTT) at a final concentration of 5 mM for 1 hour at room

588 temperature. To alkylate oxidized cysteines, 2-Iodoacetamide (IAA) was added to the samples

589 until a concentration of 40 mM was reached and incubated for 30 min in the dark. Lys-C was

590 added in a ratio of 1:100 (0.1 μg enzyme for 10 μg protein) and incubated for 2-3 hours.

591 Samples were finally diluted with ABC buffer to reach 2M urea concentration. Protein digestion

592 was performed overnight with trypsin 1:100. Samples were acidified with 1% formic acid and

593 desalted using a modified version of the previously described Stop and Go extraction tip

594 (StageTip) protocol [71].

595

596 **Pulsed SILAC labeling in mice and in-solution digestion**

597   For pulsed SILAC labeling mice, 30-40 weeks old mice for K320E; Mlc1 line (C57BL/6J) were

598   fed a $^{13}C_6$-lysine (Lys6)-containing mouse diet (Silantes) for 14 days to monitor newly

599   synthesized proteins by comparing the incorporation of Lys-6 with the naturally occurring Lys-0

600   [72]. Mice were sacrificed at the end of day 14 and tissues dissected and snap-frozen in liquid

601   nitrogen. Samples were grinded and proteins extracted and denatured by the addition of 4%

602   SDS in PBS. To remove residual SDS proteins were precipitated overnight in 4x ice-cold

603   acetone (v:v). On the next day after centrifugation at 16,000 g for 10 min the protein pellets

604   were dissolved in urea buffer (6 M urea / 2 M thiourea). The following protein digestion was

605   performed as described previously but instead of overnight tryptic digestion proteins were only

606   digested with Lys-C (1:100 enzyme-to-protein ratio) for both pre-digestion (2h at RT) and

607   overnight digestion after dilution of urea using ABC buffer.

608

609   **Liquid chromatography – mass spectrometric analysis**

610   Both affinity-enriched and pulsed SILAC proteomics samples were analyzed in positive mode

611   using data-dependent acquisition (DDA) either by an Easy-nLC 1000 – Q Exactive Plus or an

612   Easy-nLC 1200 – Orbitrap Eclipse tribrid system (all Thermo Fisher). On-line chromatography

613   was directly coupled to the mass spectrometric systems using a nanoelectrospray ionization

614   source. Peptides were separated by reversed-phase chromatography with a binary buffer

615   system of buffer A (0.1% formic acid in water) and buffer B (0.1% formic acid in 80%

616   acetonitrile) using a 60 min chromatographic gradient for IP samples and 120 min for pulsed

617   SILAC samples. Separation was performed on a 50 cm long in-house packed analytical column

618   filled with 1.9 µM C18-AQ Reprosil Pur beads (Dr. Maisch). Using the 60 min chromatographic

619   gradient peptide separation based on their hydrophobicity was performed by linearly increasing

620   the amount of buffer B from initial 13% to 48% over 35 min followed by an increase of B to 95%

621   for 10 min. The column was washed for 5 min and initial column conditions were achieved by

622   equilibrating the column for 10 min at 7% B. Full MS spectra (300 to 1750 m/z) were acquired

623   with a resolution of 70,000, a maximum injection time of 20 ms and an AGC target of 3e6. The

624   top 10 most abundant peptide ions were isolated (1.8 m/z isolation windows) for subsequent

625   HCD fragmentation (NCE = 28) and MS/MS recording at a resolution of 35,000, a maximum

626   injection time of 120 ms and an AGC target of 5e5. Peptide ions selected for fragmentation

627   were dynamically excluded for 20 seconds.

628   Using the 120 min chromatographic gradient peptides were separated by linearly increasing B

629   from initial 4% to 25% over 96 min followed by an increase of B to 55% over 14 min. After a

630   steep increase of B to 95% over 2 min the analytical column was washed for 8 min at 95% B.

631   Full MS spectra (375 to 1500 m/z) were acquired with a resolution of 60,000, a dynamic

632   injection time and an automated AGC target. The top 20 most abundant peptide ions (charge

633   state 2 – 7) were isolated (1.2 m/z isolation windows) for subsequent HCD fragmentation (NCE

634   = 30) and MS/MS recording at a resolution of 15,000, a maximum injection time of 22 ms and

635   an automated AGC target. Peptide ions selected for fragmentation were dynamically excluded

636   for 60 seconds.

16

637

Data processing and analysis

639 The mass spectrometry proteomics data have been deposited to the ProteomeXchange
640 Consortium (http://proteomecentral.proteomexchange.org) via the PRIDE partner repository [73]
641 with the dataset identifier PXD023939. All recorded RAW files were processed with the
642 MaxQuant software suite (1.5.3.8 for IP data, 1.6.14 for pSILAC) [74]. For peptide identification
643 and scoring MS/MS spectra were matched against the mouse Uniprot database (downloaded
644 08/15/2019) using the Andromeda search algorithm [75]. For the affinity-enriched samples
645 multiplicity was set to one and trypsin/P was selected as digestive enzyme.
646 Carbamidomethylation was set as a fixed modification and methionine oxidation or N-terminal
647 acetylation was selected as variable modification. Peptides were identified with a minimum
648 amino acid length of seven and a false-discovery rate (FDR) cut-off of 1% on the peptide level.
649 Proteins were identified with FDR < 1% using unique and razor peptides for quantification.
650 Label-free quantification was performed using the standard settings of the maxLFQ algorithm.
651 Match between runs was activated. pSILAC data were analyzed with the same settings with
652 some modifications. Multiplicity was set to two with Lys6 as heavy isotope label. Lys-C/P was
653 selected as digestive peptide and LFQ quantification was deactivated.

654 Statistical analysis and visualization were done with the Perseus (1.6.5) and InstantClue
655 software suits [76,77]. LFQ intensities of the IP samples were log_2-transformed and filtered for
656 proteins identified in all replicates of at least one condition. Missing values were imputed by
657 random drawing of values from 1.8 standard deviations (SD) downshifted, 0.3 SD broad normal
658 distribution to simulate the lower detection limits of the mass spectrometer. To evaluate
659 principal components responsible for the variances between samples we performed a principal
660 component analysis. Further, we performed a two-sided Student's *t*-test to identify significantly
661 regulated proteins. We proceeded similarly for the pulsed SILAC data but used the heavy-to-
662 light (H/L) ratios for statistical testing. We used the same filtering-criteria but did not imputed
663 missing values. We performed a 1D annotation enrichment to identify enriched categorical
664 terms in the different conditions [78].

665

Histology, Immunofluorescence and Microscopy

667 For tissue histology, mice were sacrificed by cervical dislocation, muscles dissected, mounted in
668 cork with OCT (Tissue-Tek), snap frozen in isopentane and stored at -80°C till needed. 10 μm
669 thick sections covering the injured area were produced using a cryostat maintained at -20°C
670 (Leica CM 3050s, Techno-med). To assess the integrity of mitochondrial function the sections
671 were sequentially stained for COX and SDH activities. Frozen sections were incubated 20 mins
672 at 37°C in COX solution (20 mg/ml catalase, 74 mg/ml sucrose, 2 mg/ml cytochrome c, and
673 1mg/ml DAB in 50mM Na_2HPO_4 pH 7.4). After 3 PBS washes, sections were then incubated for
674 30 min at 37°C in SDH staining solution (2 mg/ml NBT, 0.2M Sodium succinate, 50mM $MgCl_2$,
675 50mM Tris-HCl, pH 7.4), washed 3 times with miliQ water, and mounted in Glycerol gelatin
676 medium (Sigma).

677   For immunofluorescence of autophagy markers LC3 and p62 and mitochondrial TOM20, mice

678   were perfused with PFA 4% in PBS prior to muscle collection. Samples were equilibrated in

679   15% sucrose for 6h and 30% sucrose overnight before frozen in OCT medium. For LC3 IF,

680   samples were preincubated with 0.1% SDS for 5min. Antibody specificity was determined in

681   muscle sections from LC3-GFP transgenic mice (kindly provided by Dr. Evangelos Kondilis).

682   Cryosections were blocked for 1h with 1% Western blocking reagent (Roche) containing 0.1%

683   Triton in PBST, antibodies incubated overnight at 4°C and secondary antibodies at room

684   temperature for 1h in blocking buffer. Samples were mounted in Fluoromount G containing

685   DAPI. Fiber type staining was performed as described previously [26]. Images were obtained with

686   Leica SP8 with 63x/1.40 oil PL Apo objective.

687   For *in vitro* analysis, cells were fixed in 4% PFA/PBS, permeabilized with PBS-0.2% Triton-

688   X1000 for 30 min and blocked for 1 hour at RT in blocking buffer (5% fat free milk powder, 10%

689   FBS, 1% BSA, 0.1% Triton-X100 in PBS). Primary antibodies were incubated in blocking buffer

690   over night at 4°C and secondary antibodies for 1 hour at RT. mtDNA replication rate was

691   determined by pulse BrdU labelling. Briefly, cells were incubated with 20 µM BrdU (Sigma) for

692   6h, fixed with 4% PFA/PBS for 30 minutes and directly permeabilize with 05% Triton X-100 on

693   ice for 5 min. To allow access to mtDNA, cells were incubated with HCl 2N for another 30 min

694   prior to immunofluorescence. Coverslips were mounted using DAPI-Fluoromount G. Images

695   were acquired using a spinning-disk confocal microscope (Ultra View VoX; PerkinElmer) with a

696   Plan-Apochromat total internal reflection fluorescence 60Å~/1.49 NA oil DIC objective, Leica

697   SP5 microscope controlled by Las AF 3 with 2.5x extra magnification and Leica SP8 with

698   63x/1.40 oil PL Apo objective. Microscopy Live imaging was performed in spinning-disk confocal

699   microscope (Ultra View VoX; PerkinElmer). Cells were seeded onto glass plates and loaded

700   with 500nM Mitotracker green for 30 minutes. Videos were recorded taking 1 picture/min at

701   37°C and 5% CO_2.

702   Antibodies used for immunofluorescence were: rabbit polyclonal α-V5 (Thermo); rabbit

703   polyclonal α-TOM20, mouse monoclonal α-Vsp35 and mouse monoclonal α-8-OHdG (Santa

704   Cruz); goat polyclonal α-Vsp35 and mouse monoclonal α-dsDNA (Abcam); rabbit polyclonal α-

705   ATAD3, rabbit polyclonal α-LC3, rabbit polyclonal α-p62, rabbit polyclonal LRPPRC

706   (Proteintech); and monoclonal α-BrdU (BD Bioscience). Fluorescence secondary antibodies

707   goat α-mouse, α-rabbit Alexa Fluor-488, 555 and 647 and rabbit α-goat-647 were used

708   accordingly to the primary antibodies. Additionally, α-mouse IgM Alexa Fluor 488, α-mouse IgG

709   Alexa Fluor 555 and α-mouse IgG2b Alexa Fluor 647 were used for fiber type triple staining.

710

711   **Electron microscopy**

712   For electron microscope cells were grown on small discs of aclar foil and fixed for 1 h in 2%

713   Glutaraldehyde with 2 %Sucrose in HEPES buffer pH 7,4. After washing two times with 0.1M

714   Cacodylate buffer, free aldehyde groups were quenched with 0.1M Glycin in 0.1M Cacodylate

715   buffer for two times 20 min. After a short wash with 0.1M Cacodylate buffer, cells were

716   incubated in 0.5mg/ml Diaminobenzidine in 0.1M Cacodylate buffer and, after 10 min, a final

717 concentration of 0.03% H_2O_2 added and incubated for 30min. Finally, cells were washed three

718 times with 0.1M Cacodylate buffer and incubated with 1% Osmiumtetroxid and 1.5% Potassium

719 hexacyanoferrat for 30 min at 4°C. After 3x5min wash with ddH2O, samples were dehydrated

720 using ascending ethanol series (50%, 70%, 90%, 100%) for 5 min each and infiltrated with a

721 mixture of 50% Epon/ethanol overnight at 4°C and with pure Epon for two times 2 h. Samples

722 were embedded into TAAB capsules and cured for 48 h at 60°C.

723 For electron tomography Ultrathin sections of 200 nm were cut using an ultramicrotome (Leica,

724 UC7) and incubated with 10 nm protein A gold (CMC, Utrecht) diluted 1:25 in ddH20. Sections

725 were stained with 2% Uranyl acetate for 20 min and Reynolds lead citrate solution for 3 min.

726 Images and Tilt series for 1nm thickness were acquired from -65° to 65° with 1° increment on a

727 JEM-2100 Plus Transmission Electron Microscope (JEOL) operating at 200kV equipped with a

728 OneView 4K 32 bit (Gatan) using SerialEM (Mastronarde, 2005). Reconstruction was done

729 using Imod (Kremer et al.,1996).

730

731 **Image analysis**

732 All image analysis was performed in FIJI (NIH, Bethesda). LC3 and p62 puncta quantification

733 were performed with the "counting cells" internal plugin for particles bigger than 2 pixels to

734 exclude background. mtDNA foci quantification, VPS35-Twinkle analysis, 8-OHdG and BrdU

735 analysis were performed with a self-created macro. Briefly, threshold was set for the different

736 channels. Nuclear signal was selected and removed for the analysis. The signal corresponding

737 to the mitochondrial network was selected and only the particles from the other channel bigger

738 than 1 pixel inside the mitochondrial network were considered to the analysis. For VPS35, the

739 minimum size was determined to be 3 pixels. After thresholding, all VPS35 particles were

740 summarized and the ones in contact with Twinkle or LRPPRC were used to get a percentage.

741 Manders´ coefficient was obtained using JaCOP plugin. (Bolte & Cordelieres, 2006).

Figure 1. *In vivo* expression of Twinkle-K320E induces differential accumulation of mtDNA alterations in muscles. (**a**) Long range PCR analysis, (**b**) quantification of mtDNA copy number and, (**c**) qPCR quantification of deletion mtDNA-Δ983-4977 in M. soleus and M. Tibialis anterior from 24 months old control and K320E^SkM mice. (**d, e**) Western blot analysis and quantification of the indicated proteins in muscle extracts from 24 months old mice. M. soleus, control: n=3; Twinkle-K320E: n=4. M. tibialis anterior, control: n=4; Twinkle-K320E: n=4. (**f, g**) Western blot analysis and quantification of LC3 flux (LC3-II/LC3-I ratio) in muscle extracts from mice treated with saline or 50mg/kg chloroquine 4 hours before euthanasia. n=4 mice per treatment and genotype. Unpaired Students´ T-test. Mean ± SEM. (**h**) Volcano plots for mitochondrial and non-mitochondrial proteins detected in the muscles analysed for *in vivo* Pulse SILAC. Red dots: mitochondrial proteins; dark red: mitochondrial proteins with significant difference; blue dots: non mitochondrial proteins with significance difference. (p-value < 0.05 and a H/L ratio fold change > 1.5). n=5.
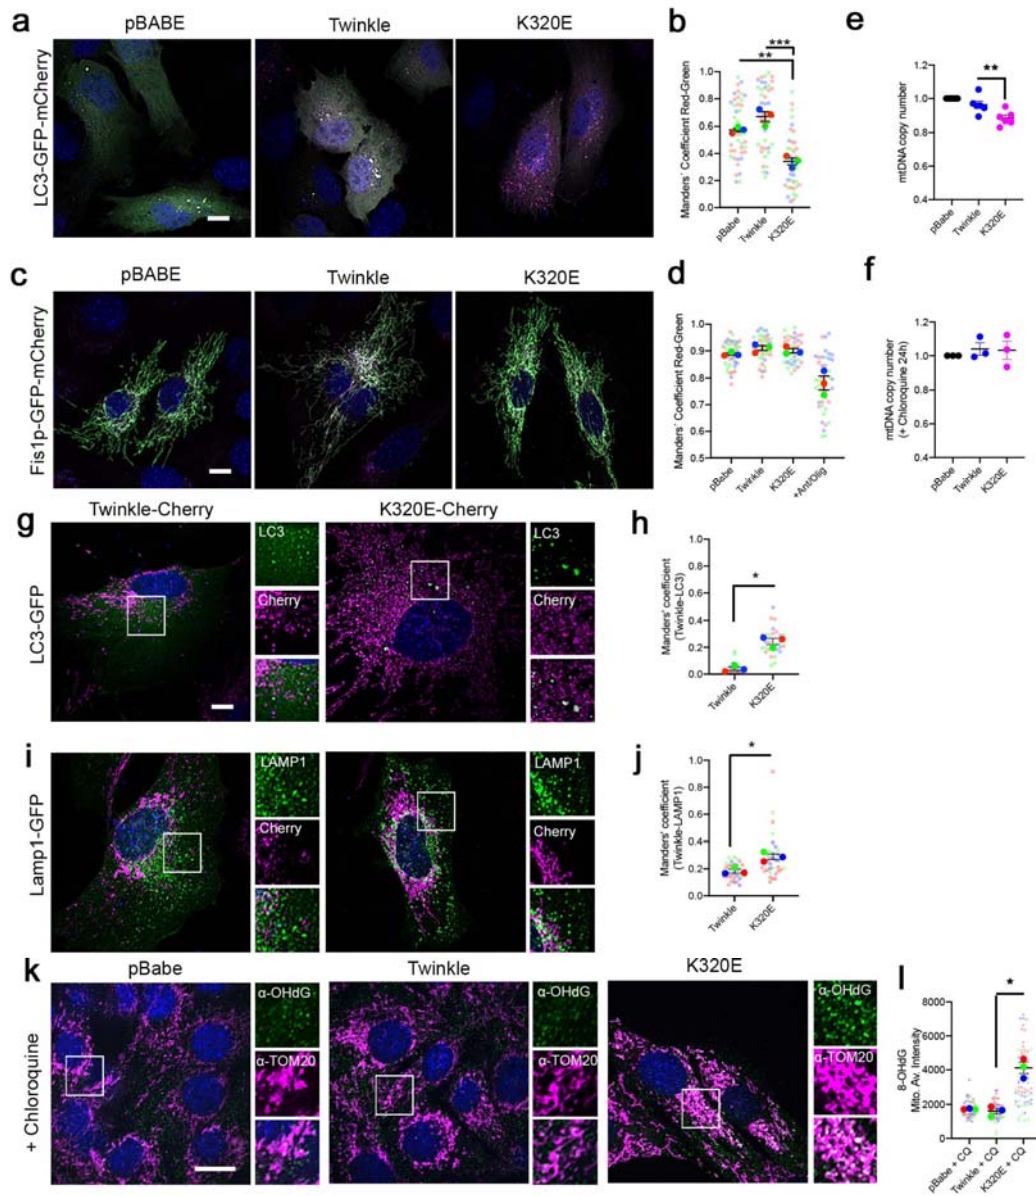

Figure 2. **Twinkle-K320E triggers mtDNA damage and induces autolysosome accumulation independent of bulk mitophagy**. (**a-e**) C2C12 expressing untagged Twinkle constructs transiently expressing the autophagy reporter LC3-GFP-mCherry or (**c**) the mitophagy reporter Fis1p-GFP-mCherry. Red signal shows lysosomal localization. (**b, c**) Manders´ coefficient Red / Green quantification of transfected cells. n=3. A decrease in Manders´ coefficient indicates autolysosome or mito-lysosome accumulation, n=3, 10-15 cells per replicate. Cells treated overnight with 10µM Antimycin/Oligomycin were used to induce canonical mitophagy. (**e, f**) mtDNA copy number in C2C12 cells stably expressing Twinkle or Twinkle-K320E (K320E), respectively, vs. empty vector (pBABE). In (**f**), mtDNA levels were recovered by treating cells with the lysosomal inhibitor chloroquine for 24h, n=3. (**g-h**) Confocal images and quantification of C2C12 expressing mCherry tagged Twinkle transfected with plasmids encoding the autophagosome marker LC3-GFP and (**i, j**) lysosome marker Lamp1-GFP. Manders´ colocalization coefficient was used to confirm Twinkle colocalization with autophagic organelles, n=3 (>10 cells per experiment). (**k**) mtDNA oxidative damage detected by immunofluorescent labelling with α-OHdG and α-TOM20 in cells expressing Twinkle and treated with chloroquine (CQ) for 24h. (**l**) Relative intensity quantification of α-OHdG signal inside the mitochondrial network. Scale Bar, 10µm. (**c-f** and **l**) ANOVA, Tukey multiple comparison. **, p<0.01; ***, p<0.001. (**h** and **j**) Unpaired Student´s T-test. *, p<0.05. Mean ± SEM.
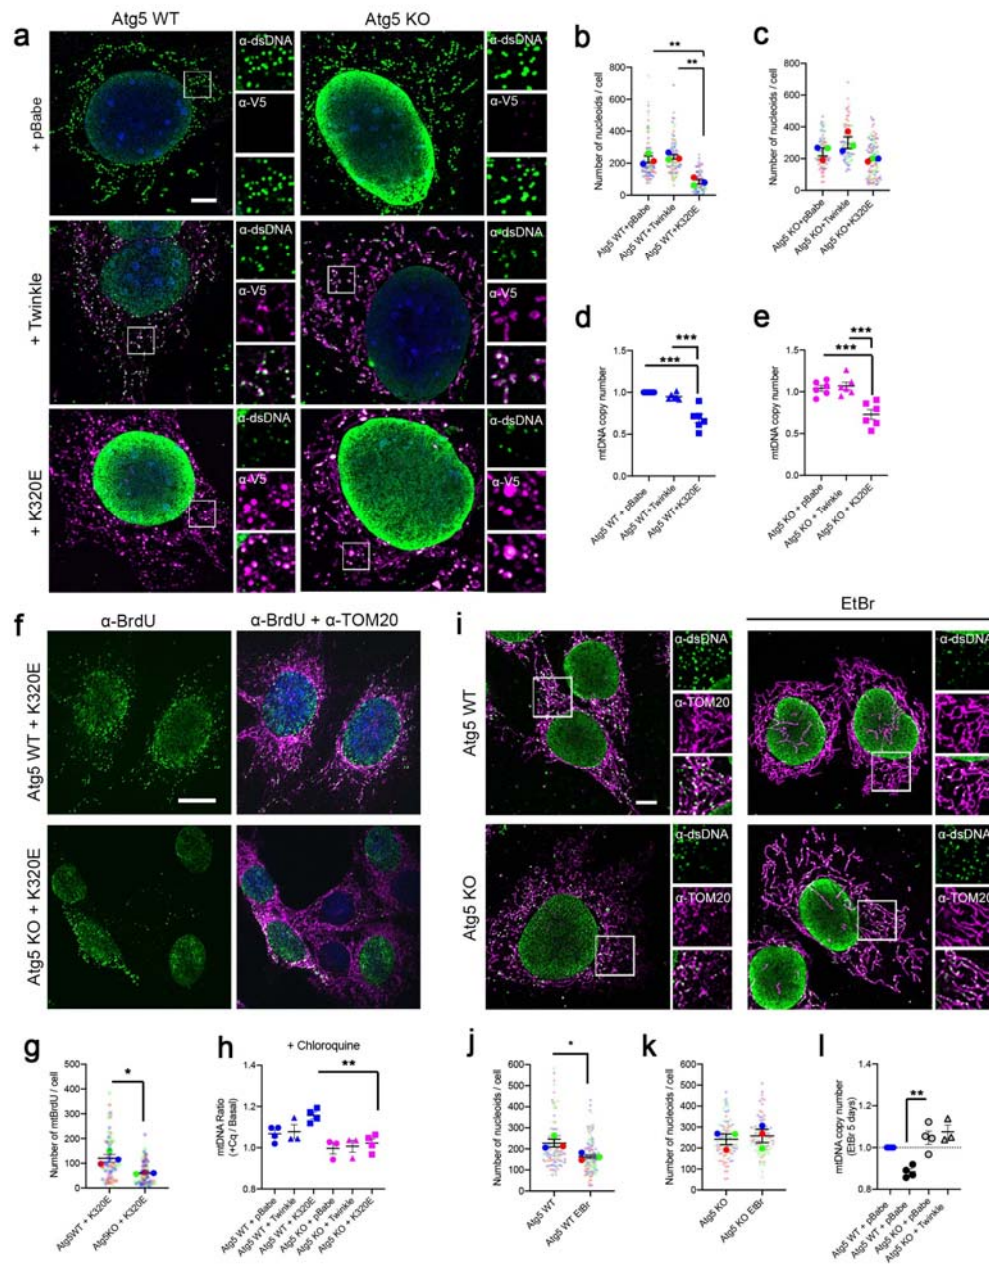

Figure 3. **Autophagy is required for mtDNA clearance after mtDNA damage.** Atg5 WT and KO cells were transduced with Twinkle-APEX-V5 plasmids. **(a)** α-DNA and α-V5-tag immunofluorescence confirming localization of Twinkle in mtDNA containing nucleoids. Scale bar 5µm. **(b, c)** Quantification of mtDNA foci number in Atg5 WT and Atg5 KO cells. n=3 (>25 cells per experiment). (**d, e**) Steady state mtDNA copy number in Atg5 cells. (**f, g**) α-BrdU and α-TOM20 immunofluorescence and quantification of mtDNA replicating foci detected by treating the cells for 6h with 20µM BrdU. n=3, >20 cells per replicate (**h**) Quantification of mtDNA copy number ratio in Atg5 cells treated with Chloroquine for 24h. n=3. (**i-k**) α-DNA and α-TOM20 immunofluorescence and mtDNA foci quantification in steady state and in cells treated with 50ng/ul EtBr for 7 days. n=3, >20 cells per replicate. (**l**) mtDNA copy number analysis for steady state and in cells treated for 7 days with EtBr. n=3-4. Scale Bar, 10µm. (**b-e, h** and **l**) ANOVA, Tukey multiple comparison. **, p<0.01; ***, p<0.001. (**g, j** and **k**) Unpaired Student´s T-test. *, p<0.05. Mean ± SEM.
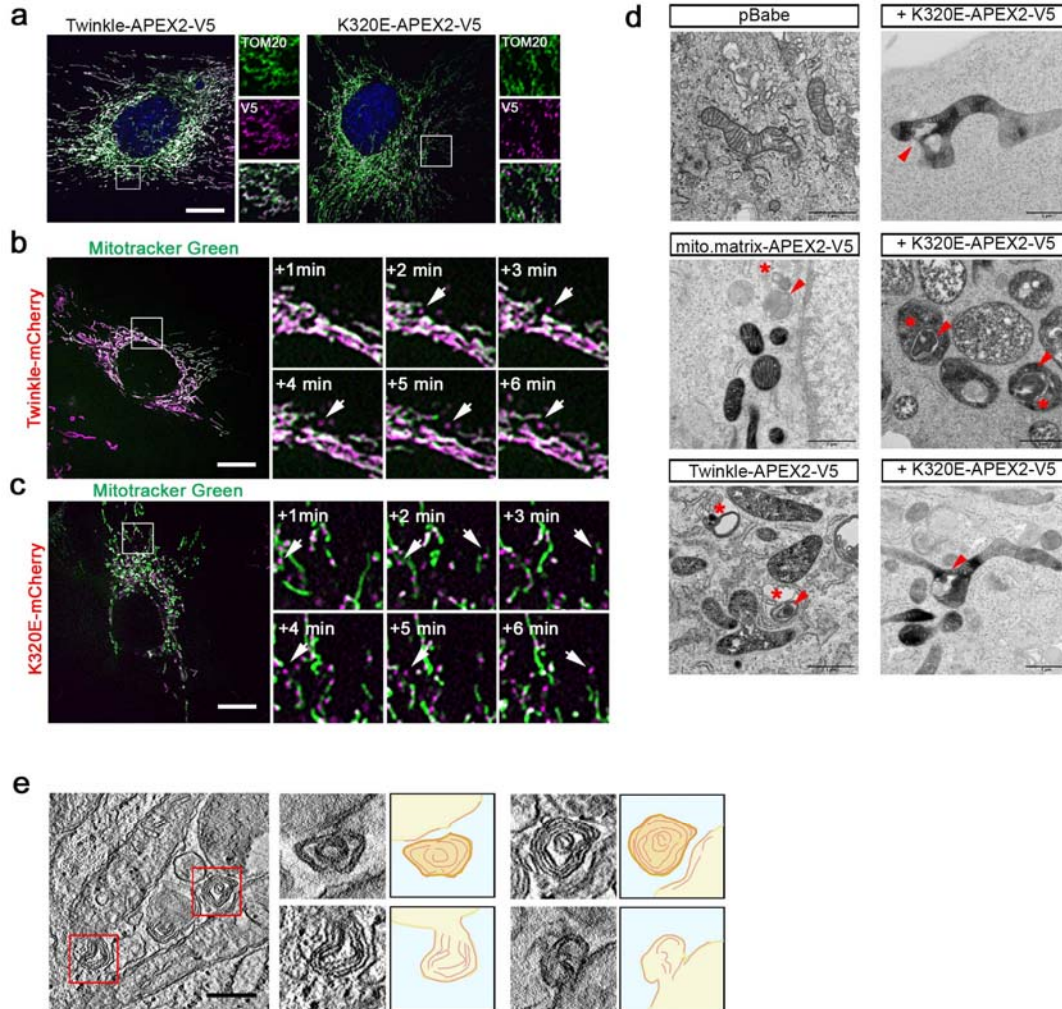

Figure 4. Twinkle-K320E localizes to specialized mitochondrial regions. (**a**) Immunofluorescence of C2C12 cells expressing Twinkle-APEX-V5 variants probed with α-TOM20 and α-V5 antibodies. Arrow shows TOM20 negative particle containing Twinkle-K320E. Bar, 10μm (**b, c**) Live imaging of C2C12 cells expressing tagged Twinkle-m-Cherry variants counterstained with mitotracker green. Insets represent a 1 min time lapse series of the selected area. Bar, 10μm (**d**) Transmission electron microscopic pictures of C2C12 cells expressing APEX2-V5 clones. APEX2 generates a black precipitate in presence of DAB. Red arrows indicate multimembrane structures, asterisks indicate autophagosomes. Bar, 1μm. (**e**) Electron tomography in C2C12 cells expressing Twinkle-K320E illustrating extrusion of mitochondrial fragments containing multimembrane structures. Bar, 0,5μm
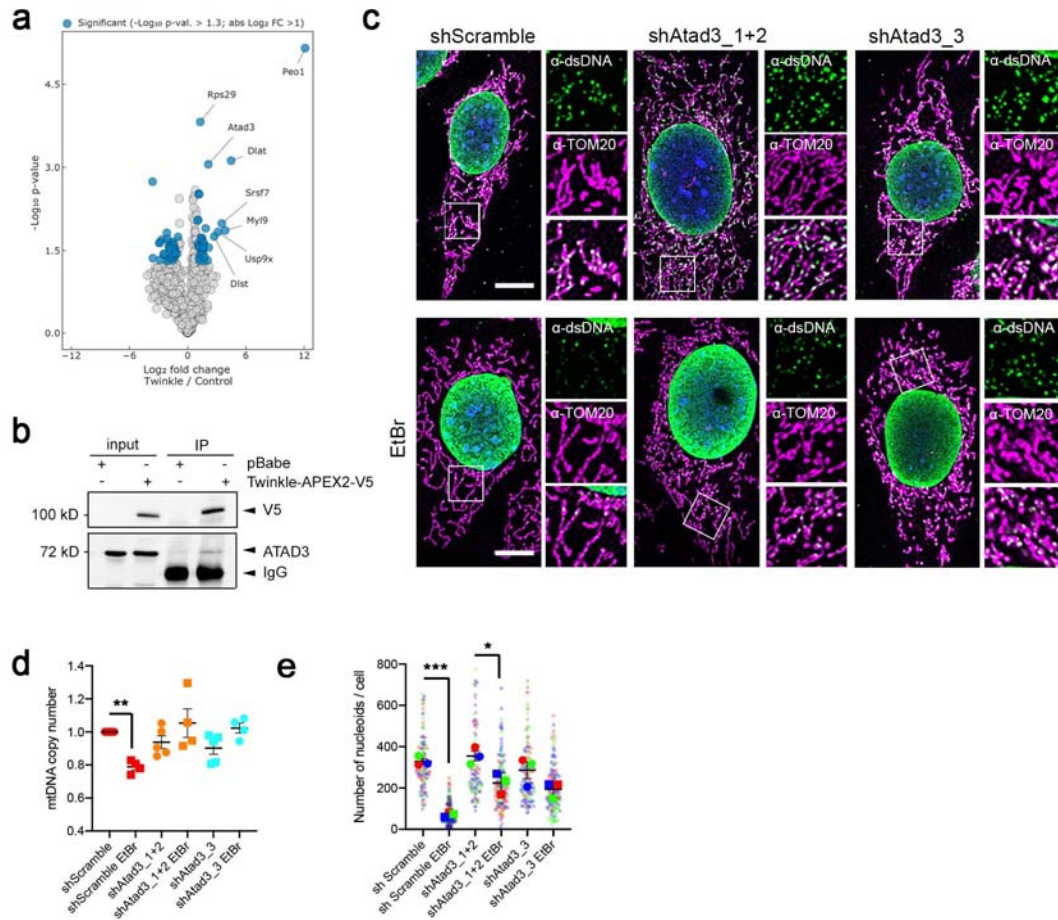

Figure 5. Twinkle mediates interaction of nucleoids with the inner mitochondrial membrane protein ATAD3. (**a**) Volcano plot showing proteins enriched after immunoprecipitation of Twinkle-APEX2-V5 in C2C12 cells. Differentially enriched proteins compared with cells transfected with empty vector (p-value < -0.05 and FC > 2 or < -2) are highlighted in blue (Peo1 = Twinkle). (**b**) Co-immunoprecipitation of V5-tagged Twinkle and ATAD3. (**c**) α-TOM20 and α-dsDNA immunofluorescence in Atad3 KD MEFs in steady state and grown for 7 days in presence of 50ng/ml EtBr. Bar, 10 µm. (**d**) Quantification of mtDNA copy number in steady state and EtBr treated cells. n=4-5. and (**e**) mtDNA foci quantification for Atad3 KD in steady state and EtBr treated cells. n=3, >20 cells per replicate. ANOVA, Tukey multiple comparison. *, p<0.05, **, p<0.01. Mean ± SEM.
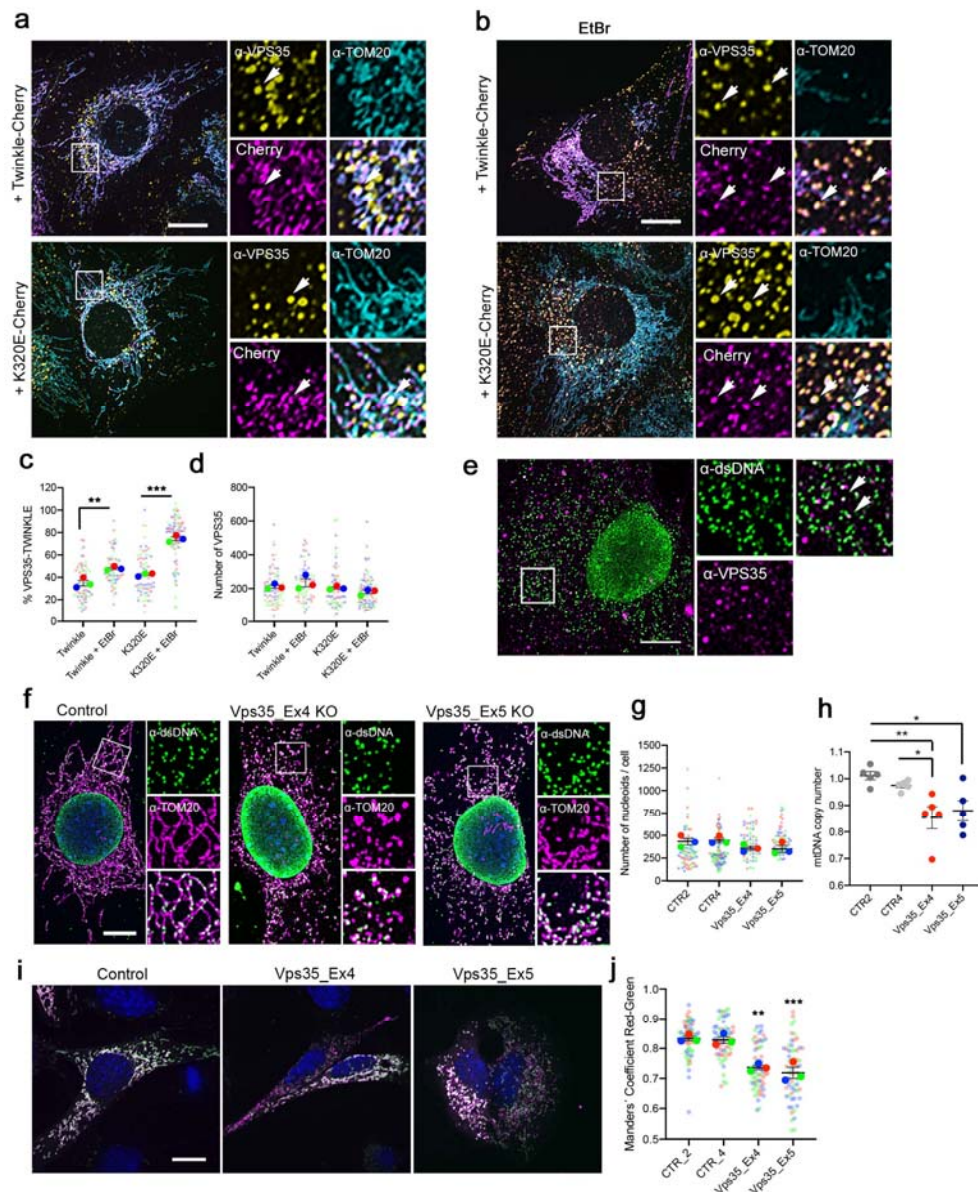

Figure 6. VPS35 is required for autophagy-dependent mtDNA removal. Immunofluorescence of C2C12 cells expressing Twinkle-mCherry variants labelled with α-VPS35 and α-TOM20 and grown in (**a**) basal medium or (**b**) treated for 7 days with 50ng/ml EtBr. Arrows indicate colocalization. Bar, 10µm. (**c, d**) Quantification of VPS35 particles in contact with Twinkle. n=3 (**e**) Immunofluorescence of C2C12 wild type cells labelled with α-dsDNA and α-VPS35. Arrows indicate colocalization between VPS35 and dsDNA puncta. Bar, 10µm. (**f**) α-TOM20 and α-dsDNA immunofluorescence of *Vps35* KO MEFs. Bar, 10µm. (**g**) mtDNA foci analysis (n=3) and (**h**) mtDNA copy number quantification of *Vps35* KO cells. n=5. (**i**) Control and *Vps35* KO cells transfected with Fis1p-GFP-mCherry plasmid to detect mitophagy. Red signal represents mito-lysosomes. Bar, 10µm. (**j**) Manders´ coefficient quantification of transfected cells. n=3. A decrease in Manders´ coefficient indicates process activation. n=3 (20 images per replicate). ANOVA, Tukey multiple comparison. *, p<0.05; **, p<0.01; ***, p<0.001. Mean ± SEM
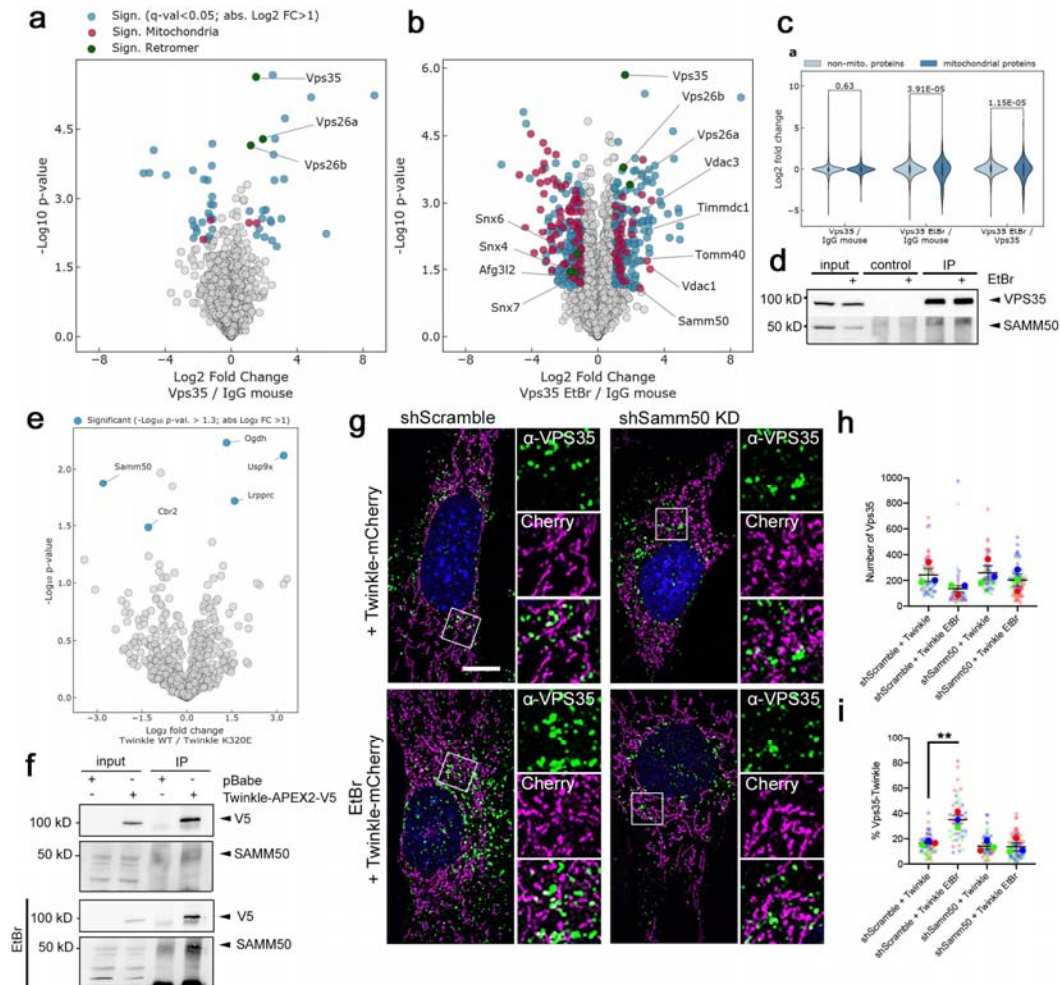

Figure 7. SAMM50 is a mitochondrial receptor for VPS35 recruitment into mitochondrial subcompartments containing nucleoids. (**a**) Volcano plot showing proteins enriched after immunoprecipitation of VPS35 in MEFs. Only differentially enriched proteins are highlighted (adj. p-value <0.05 and FC >2 or <-2). Blue, non-mitochondrial proteins; Red, mitochondrial proteins; Green, retromer proteins (**b**) Comparison of VPS35 IP profiles of cells grown in normal medium or 1 week treated with 50ng/ml EtBr. n=3. (**c**) Violin Plots showing enrichment of mitochondrial proteins upon pull down of VPS35 in presence of EtBr. Numbers indicate p-value. Students´ T-test. (**d**) Co-Immunoprecipitation of VPS35 and SAMM50 in steady state and EtBr treated cells. IgG from mouse was used as a control. (**e**) Comparison of interactome profiles of Twinkle and K320E. n=3. (**f**) co-Immunoprecipitation of Twinkle and SAMM50 in steady state and in cells treated with EtBr for 1 week. (**g**) Immunofluorescence of control and Samm50 KD MEFs transduced with Twinkle-mCherry constructs and labelled with α-VPS35 in basal and 7 days treated with 50ng/ml EtBr. Bar, 10μm. (**h, i**) Quantification of VPS35 particles and VPS35 in contact with Twinkle. n=3, >20 cells per replicate. ANOVA, Tukey multiple comparison. **, p<0.01. Mean ± SEM
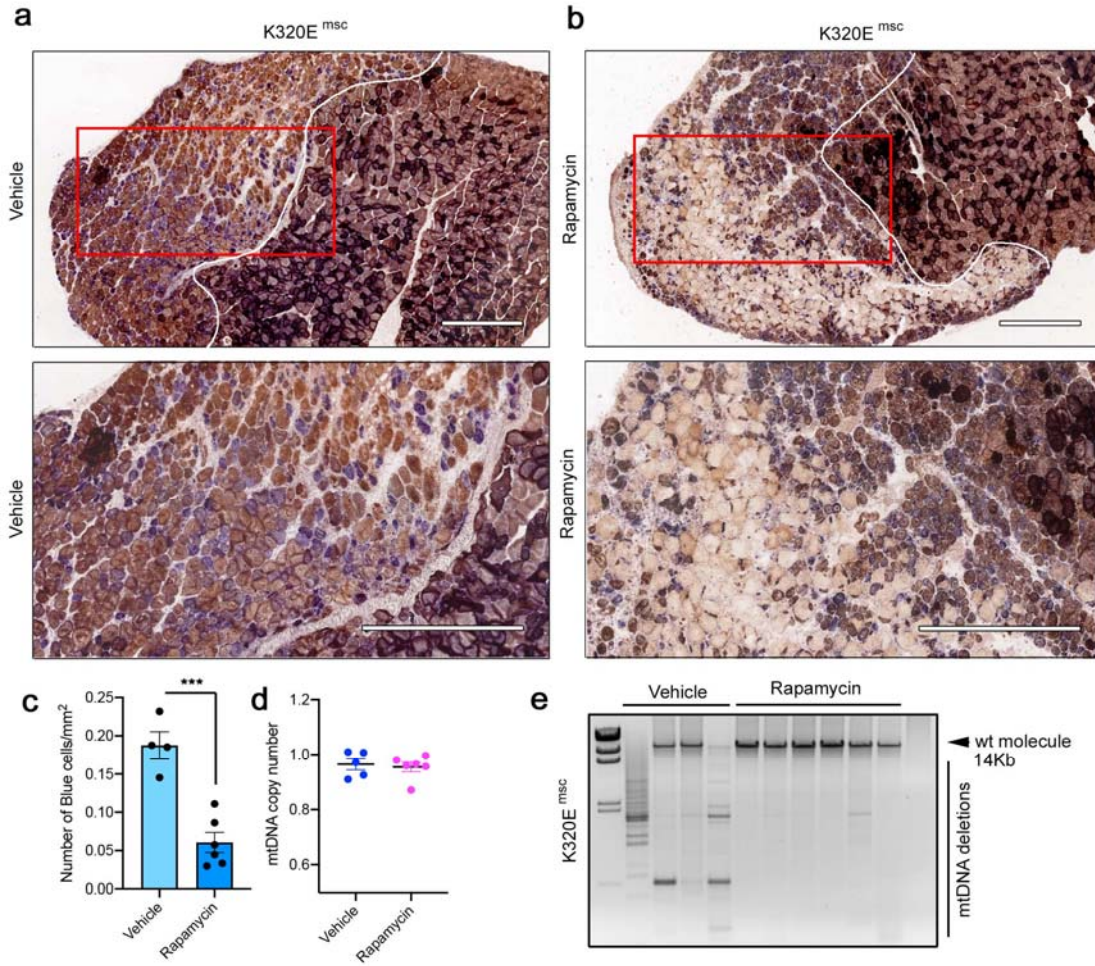

Figure 8. Rapamycin eliminates mtDNA deletions without affecting copy number *in vivo*. COX-SDH staining of regenerated TA muscle from Pax7-K320E mice (K320E^{msc}). After cardiotoxin induced injury, mice were injected for five days either with (**a**) vehicle or (**b**) 2 mg/Kg Rapamycin. Bar, 500µm. (**c**) Quantification of COX negative cells (blue) in the injured area. (**d**) mtDNA quantification by qPCR or (**e**) Long-range PCR in regenerated muscle from K320E^{msc} mice treated with vehicle or with Rapamycin. n=5-6 mice per condition, genotype and treatment. (**c** and **d**) Unpaired Students´ T-test. Mean ± SEM.
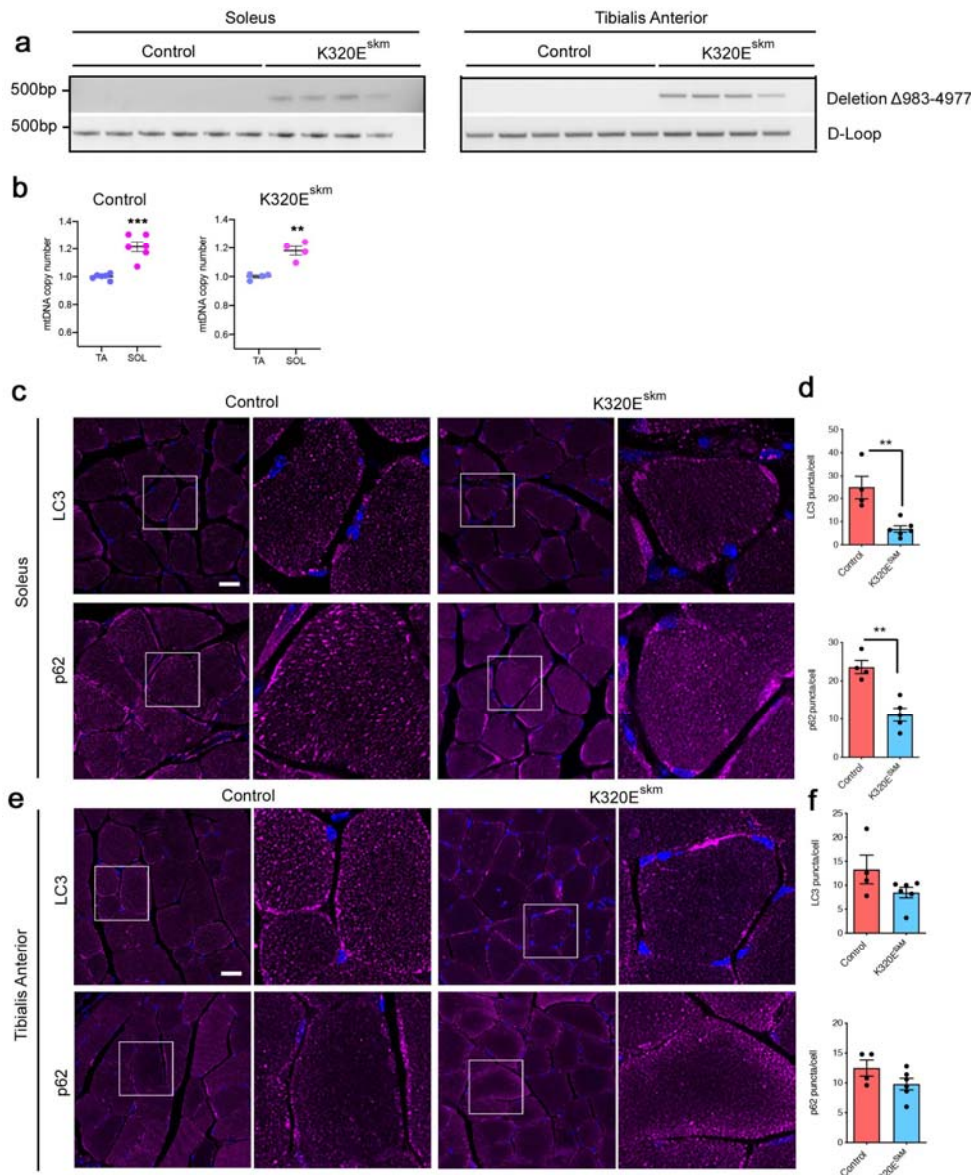

Figure S1. (**a**) Conventional PCR with specific oligonucleotides flanking the deletion mtDNA-Δ983-4977. (**b**) mtDNA copy number in muscles from 24 months old control and Twinkle-K320E mice. This graph shows a comparison between samples analysed in Fig 1b. (**c-f**) *In situ* immunofluorescence and image quantification showing autophagic markers LC3 and p62 in cryosections of M. soleus (**c, d**) and M. tibialis anterior (**e, f**). 5 random pictures with 4 fibers per picture were analysed per animal to obtain averaged values. Control: n=4; Twinkle-K320E: n=5. Bar, 20μm. (**b**, **c**, **e**, **h** and **i**) Unpaired Students´ T-test. Mean ± SEM.
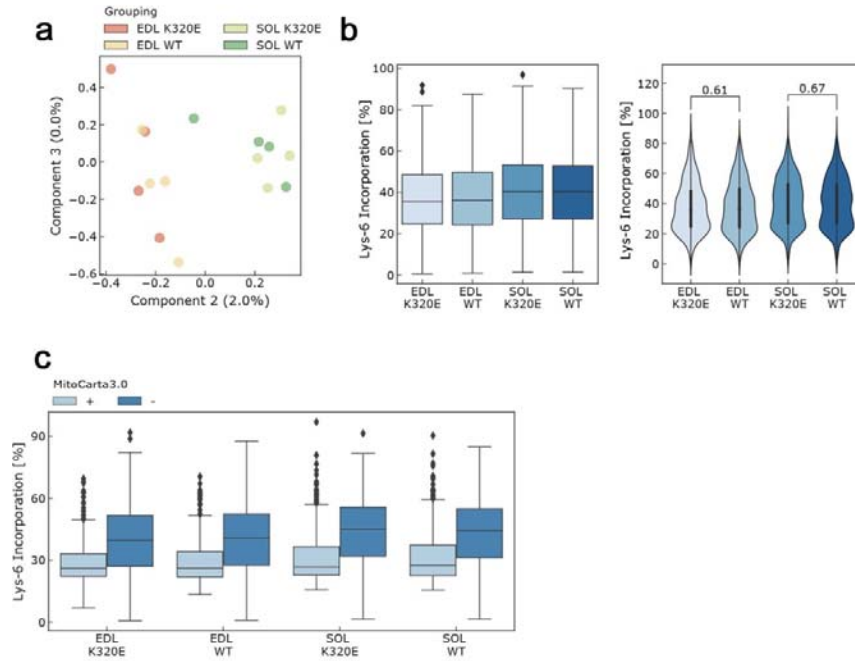

Figure S2. (**a**) Component analysis of *In vivo* Pulse SILAC in M. extensor digitorum longus (EDL) and M. soleus. (**b**) Box plot and Violin plots showing Lys-6 incorporation in muscles from Twinkle mice. (**c**) Box plot analysis for mitochondrial and non-mitochondrial proteins detected in the muscles analysed for *in vivo* Pulse SILAC. n=5.
Figure S3. (**a, b**) α-TOM20 immunofluorescence of clones expressing (**a**) m-Cherry and (**b**) APEX2-V5 tagged Twinkle variants. (**c, d**) Immunofluorescence of (**c**) m-Cherry tagged clones transiently expressing Tfam-GFP and (d) APEX-V5 tagged clones probed with α-dsDNA antibody showing nucleoid localization (see magnifications in lower panels). Bar, 10 μm.
Figure S4. (**a, b**) Analysis of mtDNA replicating foci by α-BrdU and α-TOM20 immunofluorescence of C2C12 cells expressing Twinkle plasmids treated with 20 µM BrdU. Only BrdU foci inside the mitochondrial network were analysed. (**c, d**) α-OHdG and α-TOM20 immunofluorescence and quantification of the average intensity inside the mitochondrial network of C2C12 in steady state. (**e, f**) α-OHdG and α-TOM20 immunofluorescence and quantification of the average intensity inside the mitochondrial network in C2C12 treated 24h with 50 ng/ul EtBr. Students´ T-test. Mean ± SEM. *, $p < 0.05$. Scale Bar, 10 µm.
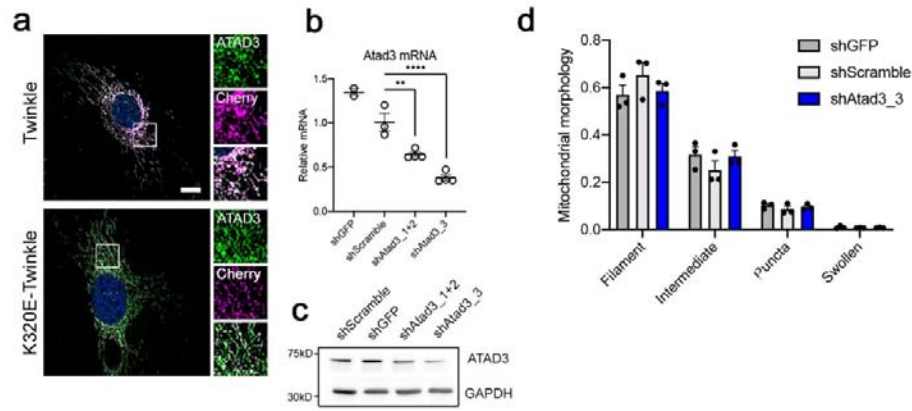

Figure S5. (**a**) Immunofluorescence of C2C12 cells expressing Twinkle-mCherry stained with α-ATAD3 antibody. Scale bar, 10 µm. (**b**) Analysis of Atad3 expression by RT-qPCR and (**c**) western blot upon shRNA transduction. n=3-4 (**d**) Quantification of Mitochondrial morphology in shATAD3 cells. n=3, >30 cells per replicate. (**b** and **d**) ANOVA, Tukey multiple comparison. **, p<0.01; ****, p<0.001. Mean ± SEM.
Figure S6. (**a-c**) Immunofluorescence of C2C12 cells expressing Twinkle-mCherry transiently transfected with MAPL-GFP and stained with α-TOM20 antibody (**a, b**) or α-VPS35 antibody (**c, d**). In (**b, d**) Cells were treated 4h with 10μM Chloroquine. Bar, 10 μm.
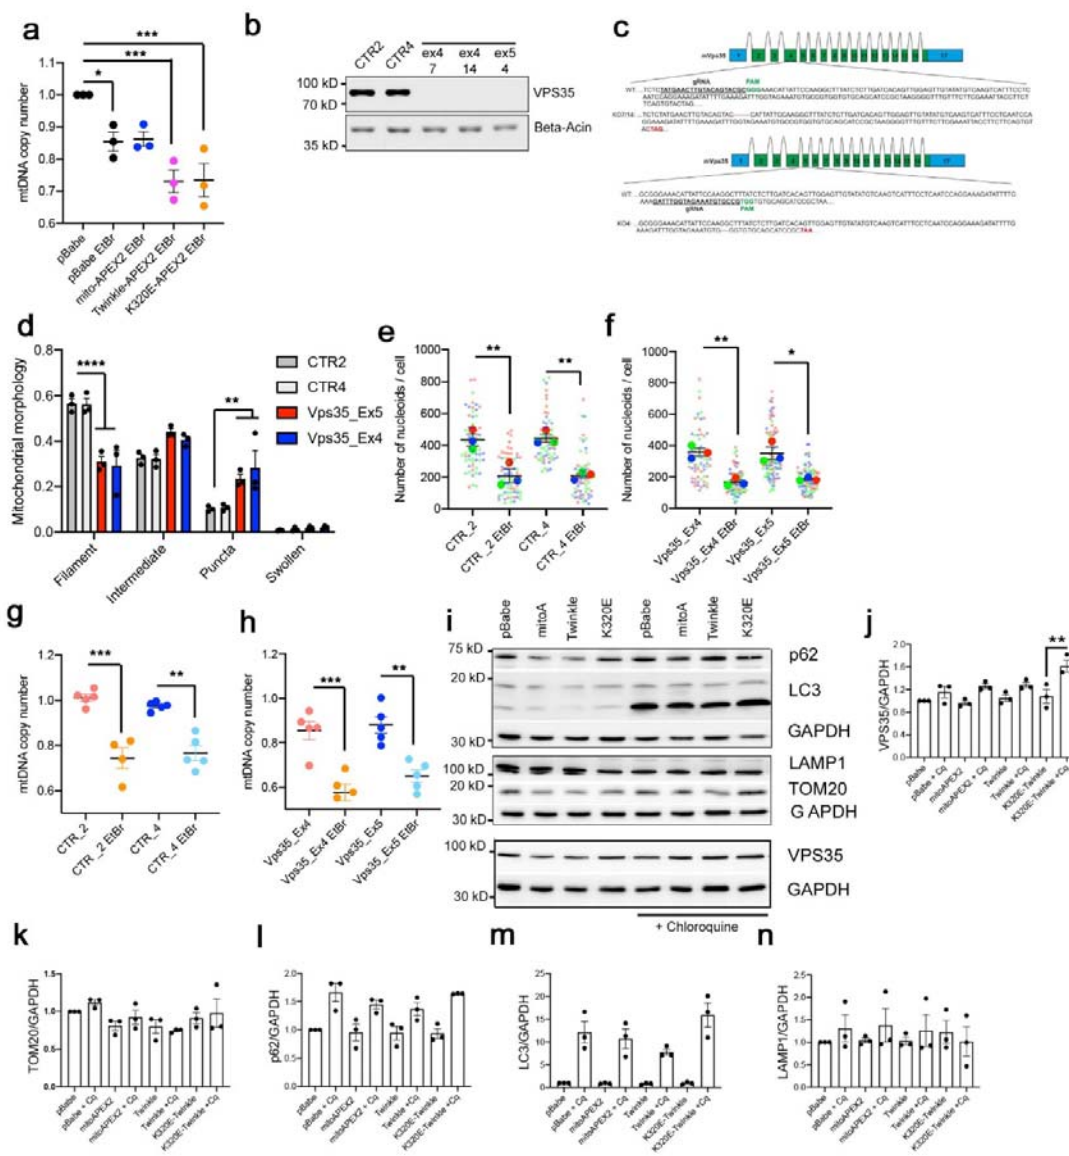

Figure S7. (**a**) mtDNA copy number in C2C12 cells treated for 7 days with 50ng/ml EtBr. n=3. (**b**) Western blot analysis of MEFs after CRISPR Cas9 mediated KO of *Vps35*. (**c**) Schematic representation of DNA modification in *Vps35* Exon 4 and Exon 5 triggered by CRISPR-Cas9. (**d**) Quantification of mitochondrial morphology in *Vps35* KO clones. n=3, >30 cells per replicate. (**e**) mtDNA foci quantification in control and (**f**) *Vps35* KO clones treated with EtBr. n=3. (**g**) qPCR mtDNA copy number analysis of control and (**h**) *Vps35* KO clones treated with EtBr. Students´ T-test. **, p<0.01; ***, p<0.001. n=5. (**i**) Western blot analysis of autophagy markers and VPS35 levels in C2C12 cells expressing Twinkle-APEX2-V5 variants (WT, KE) or matrix targeted APEX2 protein, treated 24h with 10µM Chloroquine. n=3. (**j-n**) Intensity quantification of the indicated proteins relative to empty vector pB (pBABE). (**a, g, h and j-n**) ANOVA analysis of variance. Tukey multiple comparison test. Mean ± SEM. *, p<0.05; **, p<0.01; ***, p<0.001. (**d**) Two-way ANOVA. Control lines were compared with KO lines. **, p<0.01; ****, p<0.0001.
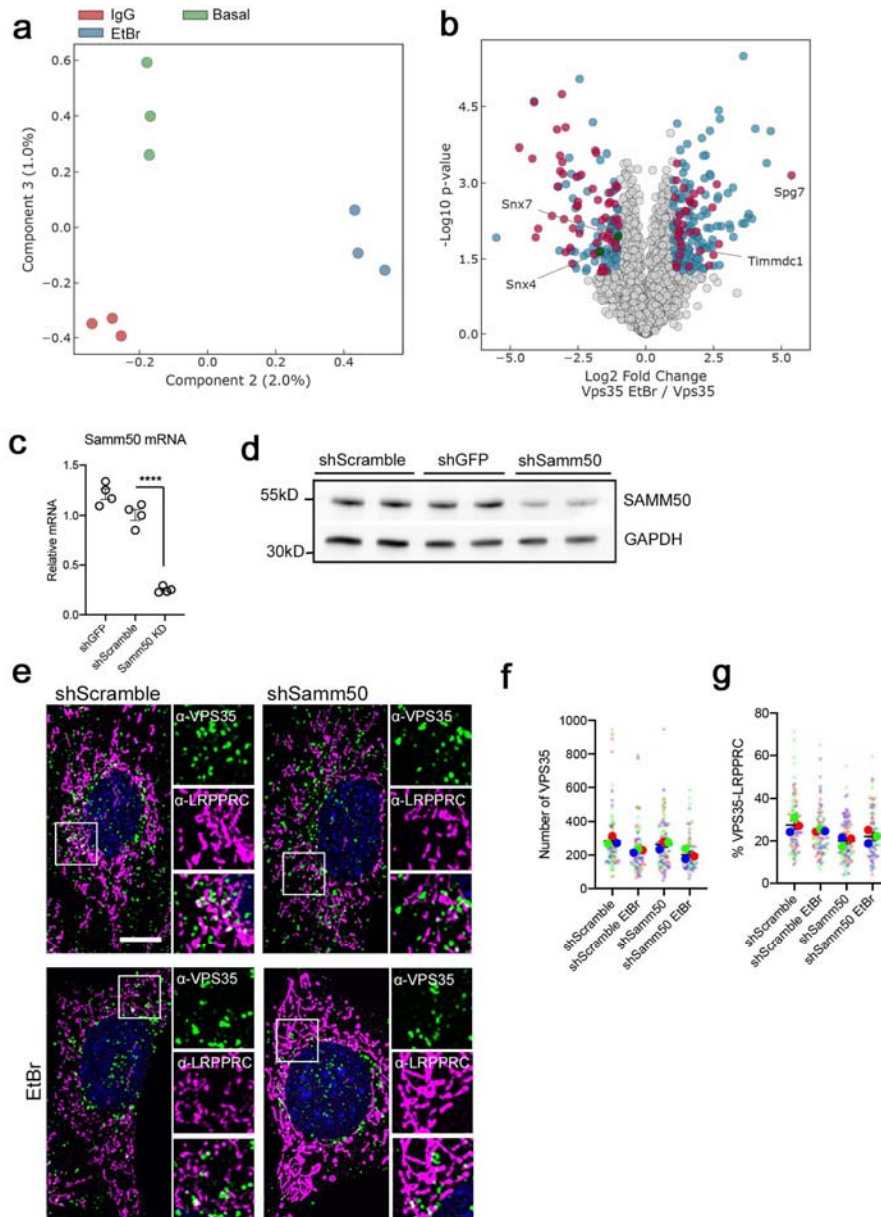

Figure S8. (**a**) Component analysis of VPS35 IP. (**b**) Comparison of VPS35 IP profiles from cells in basal medium or treated with 50ng/ml EtBr for 1 week. Only significantly different proteins are highlighted. Blue, cytosolic proteins; Red, mitochondrial proteins; Green, retromer proteins. (c) mRNA quantification and (d) western blot analysis of *Samm50* upon shRNA transduction. *Gapdh* mRNA and GAPDH was used as an internal control for both experiments. (**e**) Immunofluorescence of Control and Samm50 KD MEFs labelled with α-VPS35 and α-LRPPRC in basal and 7 days treated with 50ng/ml EtBr. Scale bar, 10μm. (**f, g**) Quantification of VPS35 particles and VPS35 in contact with LRPPRC. n=3. Mean ± SEM. ANOVA analysis of variance. Tukey multiple comparison test.
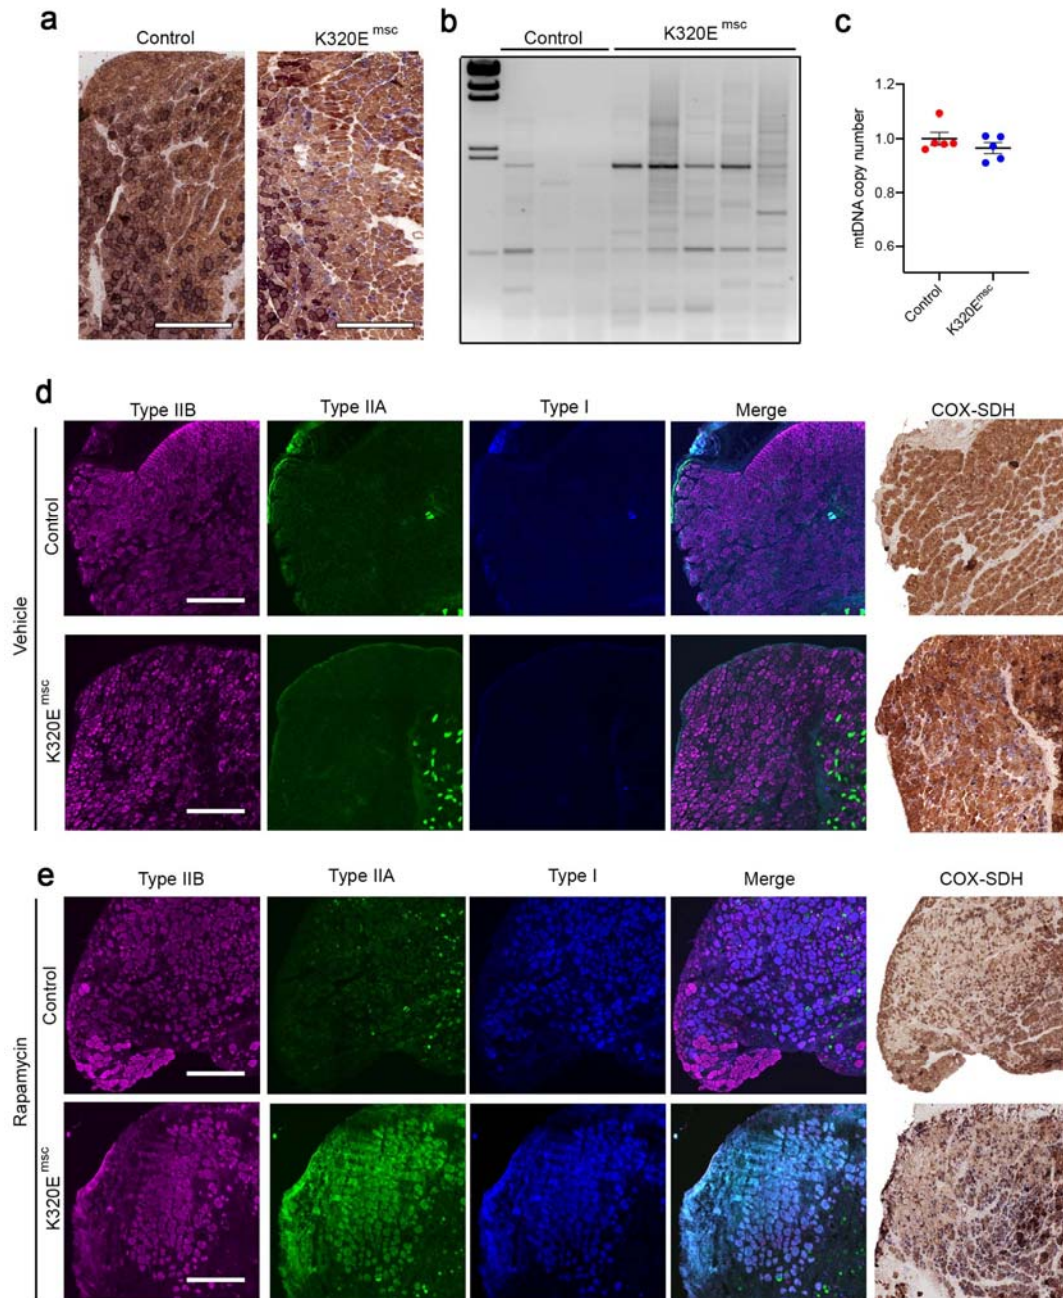

Figure S9. (**a**) Representative image for COX-SDH staining in a regenerated area from the M. Tibialis anterior from control and K320E-Twinkle^msc -mice. Bar, 500 µm. (**b**) Long Range PCR for mtDNA deletions and, (**c**) mtDNA copy number analysis in control and Twinkle-K320E mice. n=5. Muscle regeneration was induced with intramuscular injection of 10µM Cardiotoxin (*Naja Pallida*). Students´ T-test. (**d**) Fiber type and COX-SDH serial analysis of regenerated muscles in vehicle and (**e**) rapamycin treated mice. Mean ± SEM. Bar, 250 µm.
