15   **Abstract**

16   Upon fertilisation, the mammalian embryo must switch from dependence on maternal transcripts to

17   transcribing its own genome, and in mice involves the transient upregulation of MERVL transposons

18   and MERVL-driven genes at the 2-cell stage. The mechanisms and requirement for MERVL and 2-cell

19   (2C) gene upregulation are poorly understood. Moreover, this MERVL-driven transcriptional program

20   must be rapidly shut off to allow 2C exit and developmental progression. Here, we report that robust

21   ribosomal RNA (rRNA) synthesis and nucleolar maturation are essential for exit from the 2C state. 2C-

22   like cells and 2C embryos show similar immature nucleoli with altered structure and reduced rRNA

23   output. We reveal that nucleolar disruption via blocking Pol I activity or preventing nucleolar phase

24   separation enhances conversion to a 2C-like state in embryonic stem cells (ESCs) by detachment of

25   the MERVL activator *Dux* from the nucleolar surface. In embryos, nucleolar disruption prevents proper

26   *Dux* silencing and leads to 2-4 cell arrest. Our findings reveal an intriguing link between rRNA synthesis,

27   nucleolar maturation and gene repression during early development.

28

29

Introduction

Upon fertilisation, one of the earliest requirements for the development of a new organism is the formation of a totipotent zygote, which possesses the capacity to generate the entire embryo and all extra-embryonic structures. In mice, only the zygote and 2-cell stage embryo possess totipotency(Tarkowski 1959; Casser et al. 2017) with subsequent cleavages entailing a decrease in cellular plasticity as cells become specialised. Cells of the E4.5 epiblast, for example, are pluripotent, possessing the ability to generate all three germ layers of the embryo yet typically not extra-embryonic cell types(Rossant et al. 2003; Martinez Arias et al. 2013). Concurrent with the establishment of totipotency is the essential switch from reliance on maternal transcripts to activation of the embryo's own genome, termed zygotic or embryonic genome activation (ZGA/EGA). Interestingly, ZGA and totipotency at the 2-cell stage have been linked to the rapid and transient activation of several families of transposable elements (TEs), most notably MERVL(Peaston et al. 2004; Svoboda et al. 2004; Macfarlan et al. 2012).

TEs have contributed a widespread and significant source of cis-regulatory information to mammalian genomes, providing transcription factor binding sites, enhancers, and promoter sequences(Kunarso et al. 2010; Chuong et al. 2013; Sundaram et al. 2014). Many 2-cell-specific and ZGA transcripts use MERVL LTR sequences as promoters, making the MERVL-dependent transcriptome an important component of ZGA(Macfarlan et al. 2011; Macfarlan et al. 2012). In humans, specific TEs from the HERVL family are also expressed upon EGA at the 4-8 cell stage(De Iaco et al. 2017; Hendrickson et al. 2017). Several studies suggest that correct MERVL regulation is functionally important during embryogenesis. MERVL depletion impairs developmental progression(Huang et al. 2017), while overexpression in embryonic stem cells (ESCs) confers expanded fate potential: the ability in chimeras to generate both embryonic and extra-embryonic lineages, similar to 2-cell blastomeres(Yang et al. 2020). However, the functional relevance of these TEs at ZGA, as well how and why they are swiftly repressed, is still poorly understood.

Understanding of the 2-cell stage and ZGA has been enhanced by the identification of a rare, transient population of cells within ESC cultures that share several epigenetic, metabolic, and transcriptomic features with 2-cell embryos, termed 2-cell (2C)-like cells(Macfarlan et al. 2012; Boskovic et al. 2014), marked by expression of a MERVL-GFP (2C-GFP) reporter. This tool recently led to the discovery of a Dux (DUX4 in human) as a potent MERVL/HERVL and 2C activator. Dux binding directly to 2C/MERVL promoters is sufficient to convert ESCs to a 2C-like fate, and in zygotes and early 2-cell embryos drives the expression of many early ZGA and 2C-specific genes(De Iaco et al. 2017; Hendrickson et al. 2017; Whiddon et al. 2017). Since then, several 2C-activators both upstream and downstream of *Dux* have been uncovered, including both transcriptional and post-transcriptional regulators(Choi et al. 2017; Guallar et al. 2018; Eckersley-Maslin et al. 2019; Hu et al. 2020).

Surprisingly, *Dux* knockout in embryos has overall mild effects, implying the existence of parallel and redundant mechanisms to activate MERVL and ZGA *in vivo*, which remain to be discovered(Chen and Zhang 2019; Guo et al. 2019; De Iaco et al. 2020; Bosnakovski et al. 2021). In contrast, the swift attenuation of *Dux* and MERVL expression for 2-cell stage exit is likely essential both *in vitro* and *in vivo*. Dux overexpression arrests embryos at the 2-4 cell stage(Guo et al. 2019), while prolonged *Dux* overexpression in ESCs causes DNA-damage and apoptosis(Olbrich et al. 2021). Similarly, DUX4 de-repression in muscle cells causes the human disease, Facioscapulohumeral Muscular Dystrophy (FSHD), characterised by upregulation of DUX4 target genes, dsRNAs, TEs and apoptosis(Dixit et al. 2007; Geng et al. 2012; Shadle et al. 2017). Despite its importance, the mechanism for such rapid shutdown of *Dux* and MERVL gene expression at the late 2-cell stage is unclear.

Towards this, we recently reported a novel complex that is essential for *Dux* and MERVL/2C repression during early development, comprising the TE, LINE1 in association with Nucleolin (Ncl) and Kap1/Trim28 proteins(Percharde et al. 2018). LINE1 RNA in this complex is essential for proper *Dux* repression and its depletion induces the conversion of ESCs to the 2C-like state and causes 2-cell arrest in embryos(Percharde et al. 2018). At the same time, the discovery of Ncl as a *Dux* repressor implied an intriguing potential role for the nucleolus in 2-cell exit, which has not yet been explored.

Here, we investigated the impact of nucleolar dynamics and its link to *Dux* repression and 2-cell exit, using a new 2C-GFP reporter cell system and early mouse embryos. We find that 2C-like cells possess immature nucleoli with morphology akin to nucleolar precursor bodies (NPBs) that show reduced output and abrogated *Dux* repression compared to ESCs. Direct disruption of nucleolar structure and function by RNA Polymerase I inhibition (iPol I) or by perturbation of nucleolar liquid-liquid phase separation is sufficient to rapidly release *Dux* from perinucleolar regions, activate its expression, and convert ESCs into a 2C-like state. *In vivo*, short-term iPol I activates *Dux* and impairs developmental progression past the 2-4 cell stage. Our study reveals a direct link between rRNA transcription, nucleolar-based repression and cell fate during early mammalian development.

Results

The 2C-GFP/CD4 reporter enables rapid isolation of endogenous 2C-like cells

2-cell(2C)-like cells can be identified from within ESC cultures by expression of a stably-integrated fluorescent reporter (eg MERVL-GFP, 2C-GFP(Macfarlan et al. 2012; Ishiuchi et al. 2015)). These cells arise infrequently and transiently at a typical rate of less than 1-2%, making it challenging to perform large-scale or unbiased analyses in spontaneously-arising cells. Purification by flow cytometry assisted cell sorting (FACS) is laborious and slow, thus potentially perturbing biological processes(Binek et al. 2019). To perform 2C-like cell characterisation without flow sorting, we devised an improved strategy to allow FACS-free and rapid isolation of 2C-like cells. We generated ESCs stably harbouring a modified MERVL-GFP reporter, which induces expression of the extracellular portion of CD4 protein as well as GFP in the 2C state (2C-GFP/CD4+, Figure 1A). With this technique, naturally-arising 2C-like cells can

be rapidly purified from ESC cultures by magnetic bead-based isolation with a typical purity of 55-85% after only 15 minutes, more than a 100-fold increase over the starting population (Figure 1B-C, Figure S1A-B). We confirmed that 2C-GFP/CD4+ ("2C-pos") cells express markers of bona fide 2C-like cells, including high levels of MERVL and 2C-specific transcripts (Figure 1D, S1C). 2C-GFP/CD4+ cells display induction of MERVL Gag protein, together with loss of Oct4 protein and DAPI-dense chromocenters (Figure 1E-F), which are all previously-described features of 2C-like cells, and similar to 2-cell embryos (Macfarlan et al. 2012; Ishiuchi et al. 2015; Percharde et al. 2018). Thus, 2C-GFP/CD4+ cells faithfully capitulate the 2C-like state.

2C-like cell nucleoli resemble NPBs and exhibit reduced nucleolar function

We previously discovered that a ribonucleoprotein complex comprising LINE1 RNA, together with Nucleolin (Ncl) and Kap1, is essential for both ribosomal RNA (rRNA) expression as well as 2-cell exit(Percharde et al. 2018). Since Ncl and rRNA are both well-known nucleolar components, we investigated whether the 2C-like state is associated with changes to nucleoli. 2C-positive and negative cells were isolated following CD4 enrichment and examined by confocal microscopy (Figure 2A). Interestingly, we found that 2C-like cells possess a distinct nucleolar morphology, with a rounded, ring-like structure (Figure 2B-C). We next tested whether nucleolar morphological changes in 2C-like cells might also be accompanied by changes to RNA Polymerase I activity and nucleolar function. Nucleoli are the site of RNA Polymerase I-driven ribosomal RNA (rRNA) synthesis, processing, and ribosomal assembly. rRNA makes up over 70% of cellular RNA, which is tightly co-ordinated with *Rpl/Rps* RNA expression and protein synthesis(Laferte et al. 2006; Percharde et al. 2017). We measured production of nascent RNA and protein in the 2C-like versus ESC state using Click-iT assays, where a pulse of nucleotides or amino acid analogues is given to cells that are then fluorescently labelled post fixation for quantification (Figure 2A). We discovered a significant reduction in translation in 2C-like cells (Figure 2D) as well as reduced nascent RNA synthesis – the majority of which comprises nucleolar rRNA (Figure 2E, S2A, and inset). To confirm that these changes are not an artefact of CD4-based enrichment, nascent transcription and translation rates were profiled in unsorted, bulk 2C-GFP reporter ESCs(Percharde et al. 2018). In agreement, spontaneously-arising 2C-like cells exhibit reductions in nucleolar function in contrast to neighbouring ESCs (Figure 2F).

Subsequently, we investigated whether these changes are reflected at the 2-cell stage *in vivo*. Following fertilisation, 1-2 cell embryos possess immature nucleolar precursor bodies (NPBs) - largely uncharacterised structures that are initially transcriptionally silent and lacking distinct compartments(Flechon and Kopecny 1998). In contrast, mature nucleoli contain 3 sub-compartments: a fibrillar centre surrounded by a dense fibrillar component, which itself is surrounded by a granular component. In contrast to mature nucleoli, embryo NPBs are morphologically similar to 2C-like nucleoli (Figure 2B, 2G). Coincident with the increasing initiation of rRNA transcription, mature nucleoli only gradually form from NPBs at the late 2-cell stage onwards(Kyogoku et al. 2014; Borsos and Torres-Padilla 2016). We analysed nucleolar function in embryos with nascent transcription/translation assays, which demonstrated dynamic rates of biosynthesis during the 2-cell stage. Early 2-cell (E2C) embryos

149 exhibit low levels of nascent RNA synthesis but also nucleolar translation, which rapidly increases by
150 the late 2C (L2C) stage and upon 2-cell exit (Figure 2H). At the same time, Ncl protein only becomes
151 readily detectable surrounding nucleoli in L2C embryos onwards (Figure 2G), at the time when MERVL
152 and the 2-cell program is being shut down. We conclude that the 2-cell stage *in vitro* and *in vivo* is
153 characterised by significantly reduced nucleolar function and morphologically distinct nucleolar
154 structure.

155

Nucleolar disruption induces conversion to the 2C-like state

157 The observed nucleolar remodelling upon 2-cell stage exit lead us to ask whether alterations to
158 nucleolar structure and function might be drivers of the 2C-like state. We took advantage of two different
159 small molecules to inhibit Pol I and rRNA synthesis, CX-5461 - which blocks recruitment of the Pol I
160 initiation factor SL1 to rDNA(Bywater et al. 2012; Haddach et al. 2012), and BMH-21, which triggers
161 rapid Pol I degradation(Peltonen et al. 2014). We found that nucleolar disruption by mild or partial
162 inhibition of rRNA synthesis (Pol I inhibition, iPol I) is detectable by 2h (Figure S3A) and by 4h induces
163 morphological nucleolar remodelling, generating singular ring-like structures in ESCs resembling 2C-
164 like nucleoli and embryo NPBs (Figure 3B, Figure 2G). Importantly, the structures observed following
165 this milder inhibition are distinct from the nucleolar cap-like structures seen upon more extreme
166 nucleolar stress, where fibrillar proteins such as Fibrillarin (Fbl) or UBF aggregate at the nucleolar
167 periphery, or from complete dissolution of nucleolar proteins into the nucleoplasm (Figure S3B)(Shav-
168 Tal et al. 2005; Ide et al. 2020). Moreover, we did not detect gross changes to Ncl or Fbl protein
169 abundance upon iPol I (Figure S3C). Strikingly, we found that following nucleolar reprogramming, iPol
170 I causes a significant increase to 20% of 2C-like cells within ESC cultures (Figure 3C). In agreement,
171 iPol I induces high expression of 2C-specific genes and MERVL transposons (Figure 3D) along with 2C
172 proteins, Zscan4 and MERVL gag in ESCs (Figure 3E). Thus, nucleolar disruption produces 2C-like
173 nucleoli and moreover is sufficient to reprogram ESCs into the 2C-like state.

174

Nucleolar proteins driving rRNA synthesis and processing are essential for *Dux* and 2C-repression

177 These results support the hypothesis that the development of functionally mature nucleoli may play a
178 role in the repression of the 2-cell transcriptional program and for exit from the 2-cell stage. To
179 investigate this, we asked which nucleolar proteins are most important for repression of the 2C-like
180 state in ESCs and performed an siRNA miniscreen for nucleolar components in 2C-GFP ESCs. Similar
181 to the effects of Ncl loss, depletion of Pol I and Fibrillarin (Fbl) also cause a notable increase in 2C-like
182 cells (Figure 3F, S3D), while knockdown (KD) of other nucleolar proteins has limited effect. Conversely,
183 KD of Npm3, a negative regulator of ribosome biogenesis(Huang et al. 2005), leads to a small but
184 consistent reduction in 2C-GFP+ cells (Figure 3F). Confirming these results, siRNAs against Pol I, Fbl
185 and Ncl all induce high levels of 2C-specific genes and transposons (Figure 3G-H), indicating that these
186 factors are necessary for repression of the 2C-like state. Interestingly, RNA Pol I, Ncl and Fbl are all
187 known to be critical for rRNA synthesis and/or processing(Ginisty et al. 1998; Yao et al. 2019; Ide et al.

188   2020). Collectively, these data reveal an intriguing link between rRNA synthesis and 2C-repression to
189   maintain ESC identity.

190

191   Next, we asked how rRNA synthesis and nucleolar function is mechanistically linked to repression of
192   the 2C-like state. We focused on *Dux*, which is a potent 2C activator and is upregulated upon nucleolar
193   protein knockdown (Figure 3H). We performed time-course experiments of acute iPol I treatment
194   followed by qRT-PCR and RNA-seq (Figure 4A, S4A), and found that *Dux* is significantly induced as
195   early as 4h following nucleolar disruption (Figure 4A, S4B). By 8h, *Dux* targets are highly upregulated
196   amongst all significantly altered genes following iPol I (Figure 4B). Moreover, transcriptomic profiling of
197   2C-specific genes(Macfarlan et al. 2012; Percharde et al. 2018) demonstrated that MERVL and the 2C
198   program is widely upregulated following nucleolar disruption (Figure 4C, S4B-C). Next, to test whether
199   2C gene induction is dependent on Dux, we performed iPol I experiments with *Dux* siRNAs. We
200   confirmed that 2C genes are specifically upregulated by 8h iPol I, which is prevented upon *Dux*
201   depletion (Figure 4D-E)*.* We subsequently investigated whether nucleolar disruption can also prevent
202   *Dux* silencing in embryos (Figure 4F), which normally occurs rapidly as embryos transit to the late 2-
203   cell stage (Figure 4G and(De Iaco et al. 2017; Hendrickson et al. 2017)). We found that iPol I treatment
204   in mid-2C embryos leads to significant rRNA reduction and concomitant *Dux* activation in L2C-4C
205   embryos (Figure 4G-H). We observed slightly different kinetics with the two inhibitors, with BMH-21
206   causing more rapid activation of *Dux* in embryos than CX-5461 (Figure 4G-H), similar to in ESCs (Figure
207   4A). Finally, nucleolar disruption leads to an inability to progress beyond 2-4 cell stage, in contrast to
208   control embryos (Figure 4I, S4D). Together, these results indicate that nucleolar disruption rapidly leads
209   to *Dux* de-repression and promotion of the 2-cell state both in ESCs and in embryos.

210

211   **Dux is repressed in perinucleolar chromatin**
212   Prolonged treatment or high doses of drugs that perturb rRNA synthesis or cause rDNA damage is
213   known to activate nucleolar stress. In this process, disruption of nucleolar integrity releases ribosomal
214   proteins into the nucleoplasm to bind MDM2, leading to p53 stabilisation and activation followed by
215   downstream effects such as cell cycle arrest(Rubbi and Milner 2003; James et al. 2014). To understand
216   how nucleolar disruption is linked to *Dux* activation, we first tested whether this is dependent on
217   nucleolar stress. Although iPol I does not induce typical markers of nucleolar stress (Figure S3B), levels
218   of total and activated, phospho-p53 are increased upon iPol I, similar to the effect of the Topoisomerase
219   II inhibitor, etoposide, used as a positive control (Figure S5A). Interestingly, etoposide treatment also
220   increases the proportion of 2C-GFP+ cells in culture (Figure S5B), suggesting that p53 activation can
221   activate the 2C-like state. Indeed, a recent study reported DNA damage-dependent activation of
222   Dux/DUX4 and the 2C-like state via p53(Grow et al. 2021). However, we did not detect any increase in
223   phospho-p53 in endogenously arising 2C-like cells (Figure S5C). Furthermore, iPol I treatment is still
224   able to cause *Dux* activation in the absence of p53 (Figure S5D). Thus, although p53 activation is
225   sufficient to induce the 2C-like state upon DNA damage(Grow et al. 2021), it is not necessary for *Dux*
226   de-repression upon nucleolar disruption.

227

In ESCs but not 2C-like cells, we reported that *Dux* genes localise to perinucleolar regions with unknown functional relevance(Percharde et al. 2018). Mature nucleoli are surrounded by a shell of chromatin that is enriched for repressive histone marks(Nemeth et al. 2010; Lu et al. 2020) and is lowly transcribed(Quinodoz et al. 2018). We therefore reasoned that disruption of nucleolar function and morphology might lead to *Dux* upregulation by preventing its repression at the nucleolar periphery. To observe perinucleolar chromatin in more detail, we performed 3D super-resolution Structured Illumination Microscopy (3D-SIM) of DAPI staining in ESCs versus 2C-like cells. These experiments revealed a reduction in perinucleolar chromatin fibres in the 2C state (Figure 5A, orange arrows), alongside a previously-reported loss of chromocenters(Ishiuchi et al. 2015). Reduced nucleolar DNA association is moreover replicated upon BMH-21 and CX-5461 treatment (Figure 5B), suggesting that iPol I perturbs nucleolar-associated chromatin. We next examined whether nucleolar disruption alters the localisation of the *Dux* gene locus, focusing on acute inhibition to determine direct effects of iPol I. DNA FISH confirmed that *Dux* is frequently associated with perinucleolar regions in ESCs, and moreover revealed significant movement away from nucleoli to the nucleoplasm by 4h of either CX-5461 or BMH-21 (Figure 5C-D). Using 3D nuclear segmentation and analysis of *Dux* distance to nuclear compartments, we confirmed these findings and found that movement away from the nucleolus starts from 2h CX-5461 and robustly at 4h. In contrast, there is no change in *Dux* distance from the lamina (Figure S6A-C). Thus, it is only nucleolar-localised *Dux* alleles that are affected by iPol I. *Dux* movement is closely linked to reactivation of *Dux* (Figure 4A), with single-cell analysis of *Dux* transcription demonstrating that maximal nascent expression is reached by 4h iPol I (Figure S6D). Importantly, nascent *Dux* expression occurs only in the nucleoplasmic or lamina compartments, in strong agreement with the repressive nature of the nucleolus (Figure S6E).

Nucleolar-associated DNA regions (NADs) have been previously identified by isolation and sequencing of DNA associated with purified nucleoli (NAD-seq(Nemeth et al. 2010; Vertii et al. 2019)), which has confirmed the generally repressive nature of nucleolar chromatin(Lu et al. 2020). Using NAD annotations generated from ESCs(Bizhanova et al. 2020), we asked whether the expression of other nucleolar-associated genes is altered following nucleolar disruption. We looked at Type I NADs, which overlap constitutively lamina associated domains (cLADs) and are considered to comprise constitutive heterochromatin, and Type II NADs, which do not overlap LADs in multiple cell types(Peric-Hupkes et al. 2010). GSEA analysis revealed that Type II NAD genes are particularly sensitive to nucleolar disruption, and are significantly upregulated from 4h iPol I compared to all genes, in contrast to Type I NADs (Figure 5E-F). This is not an isolated effect of inhibitor treatment, as knockdown of Ncl or LINE1, both important for nucleolar function(Percharde et al. 2018; Lu et al. 2020), also lead to NAD and NAD/LAD gene upregulation (Figure 5E). Together, these results reveal that nucleolar association of *Dux* is closely tied to its repression, and suggest that iPol I induces global disruption of nucleolar chromatin organisation and gene expression.

Phase-separated nucleolar integrity is required for *Dux* repression at nucleoli

7

267 Lastly, we sought to determine the link between disrupted rRNA synthesis and *Dux* loci release and de-
268 repression. The membrane-less nucleolus is held together by liquid-liquid phase separation (LLPS),
269 which is driven by the association of rDNA with nucleolar proteins and moreover dependent on continual
270 rRNA synthesis(Feric et al. 2016; Yao et al. 2019; Ide et al. 2020). We hypothesized that the disruption
271 of rRNA synthesis may inhibit nucleolar integrity and LLPS, thus allowing the release of associated
272 DNA regions such as *Dux*. To test this, we used 1,6-hexanediol (HDL), an aliphatic alcohol used to
273 disrupt liquid-like condensates(Ribbeck and Gorlich 2002). Short-term treatment with 1% HDL – a dose
274 notably lower than typically used to disrupt non-nucleolar compartments(Vertii et al. 2019) – is sufficient
275 to alter nucleolar morphology, resembling 2C-like cells or iPol I treatment (Figure 5G). Disruption of
276 phase separation remarkably releases *Dux* loci after only 2h HDL (Figure 5H), and moreover leads to
277 significant *Dux* upregulation by 4h (Figure 5I). Furthermore, we found this to be highly dynamic, with
278 nucleolar morphology, *Dux* localisation and transcriptional repression all returning to normal after 4h
279 washout (Figure 5I). These results suggest that *Dux* localisation and repression is maintained in the
280 nucleolus through LLPS. Taken together, our data show that nucleolar disruption by several means
281 causes *Dux* reactivation, initiation of 2C/MERVL gene transcription and conversion back to the 2C-like
282 state. Overall these findings point to a novel requirement for rRNA biogenesis, nucleolar maturation
283 and nucleolar-based repression for correct cell identity during the earliest stages of embryo
284 development.

285
286

287 **Discussion**

288

289 Major ZGA is an essential process occurring at the 2-cell stage of early mouse embryogenesis, which
290 entails rapid activation of zygotic RNAs required for subsequent development. This includes a
291 significant number of transcripts driven by the TE, MERVL, which unlike other ZGA transcripts are
292 rapidly downregulated upon 2-cell exit. These dynamics swiftly follow the rapid repression of the
293 MERVL activator, Dux. Sustained Dux expression in 2-cell embryos is poorly tolerated and moreover
294 promotes persistence of the 2C program and impedes development(Percharde et al. 2018; Guo et al.
295 2019). Thus, timely Dux repression is essential, yet the mechanisms for this process are poorly
296 understood.

297

298 Here, we reveal that high rRNA synthesis and nucleolar maturation from inactive NPBs to be an
299 essential driver of *Dux* repression in embryos and 2C-like cells. The absence of pluripotency proteins
300 such as Oct4 is a well-known feature of the 2C-like state(Macfarlan et al. 2012). Here we place this
301 finding within the context of suppression of both rRNA transcription and global translation and reveal
302 that the 2C-like state is characterised by significantly reduced nucleolar function, akin to NPBs in 2-cell
303 embryos. NPBs are unique structures that in 1-2 cell embryos lack distinct compartments and exhibit
304 low rRNA synthesis(Flechon and Kopecny 1998; Borsos and Torres-Padilla 2016). Nucleolar
305 maturation occurs with the resumption of transcription, and is essential to generate high levels of rRNA
306 and promote ribosomal assembly to fuel embryonic growth. However, it is becoming clearer that nucleoli

307 also possess other roles in development. NPBs are essential for early centromeric chromatin
308 organisation, which localises to the surface of NPBs(Zuccotti et al. 2005; Fulka and Langerova 2014)
309 and nucleolus removal in oocytes causes 2-cell arrest(Ogushi et al. 2008). Intriguingly, reprogramming
310 to totipotency by somatic cell nuclear transfer (SCNT) generates NPBs after only 3h(Martin et al. 2006),
311 highlighting a link between totipotency and nucleolar biology. Here, we additionally show that 2C-like
312 cells have NPB-like nucleoli with reduced chromatin association. We propose that nucleolar maturation
313 and full nucleolar function is critical for *Dux* recruitment to the nucleolar periphery for its repression,
314 which is in turn essential for 2-cell exit. Conversely, mild inhibition of Pol I is sufficient to rapidly release
315 *Dux* from nucleolar chromatin and to activate its expression (Figure 6). In this way, we hypothesise that
316 ZGA itself provides the mechanism to shut down the 2C program, in a feedback loop whereby high
317 levels of rRNA synthesis promote nucleolar maturation that can then silence Dux.

318

319 Importantly, this mechanism of Dux regulation appears separate from nucleolar stress-mediated p53
320 activation, which is capable of directly inducing *Dux*(Grow et al. 2021). We find that iPol I ESCs or 2C-
321 like cells do not display typical nucleolar stress markers and iPol I ESCs still activate *Dux* in the absence
322 of p53. Instead, our data agree with previous nucleolar positioning studies, which demonstrated in yeast
323 that an ectopic rDNA repeat can silence its chromosomal region(Zuccotti et al. 2005), and that 5S rDNA
324 sequences are sufficient to induce nucleolar association and silencing of a reporter gene in
325 ESCs(Fedoriw et al. 2012). Indeed, NAD-seq data(Bizhanova et al. 2020) indicate that *Dux* is located
326 within a NAD (Figure S7). Interestingly, *D4Z4* repeats containing human *DUX4* have also been
327 proposed to reside within a NAD(Nemeth et al. 2010) and bound by NCL(Gabellini et al. 2002). Studying
328 nucleolar regulation of *DUX4* will allow us to understand if failure of a similar mechanism may contribute
329 to DUX4 de-repression in the disease, FSHD.

330

331 Our data raise the question of how rRNA transcription is tied to *Dux* nucleolar association and
332 repression. The nucleolus is self-organised into its three subdomains by phase separation, driven by
333 the interaction between nucleolar proteins and rDNA(Feric et al. 2016; Yao et al. 2019), and nucleated
334 by rRNA(Falahati et al. 2016). Indeed, purified Fbl and B23 (Npm1) can separate into distinct layers
335 and recapitulate the dense fibrillar component and granular component in solution(Feric et al. 2016).
336 Importantly, the phase separation properties of the nucleolus in cells rely on continual activity of RNA
337 Pol I, since its inhibition leads to disruption of these compartments(Ide et al. 2020). Our results point to
338 a model in which *Dux* is held in repressive perinucleolar heterochromatin that is maintained through
339 LLPS, with perturbation of rRNA transcription or direct inhibition of phase separation sufficient to cause
340 *Dux* dissociation and de-repression. Similarly, we propose that the NPB structures of early 2C embryos
341 and 2C-like cells are not competent for *Dux* repression. It will be interesting in future work to understand
342 in further depth how the nucleolar periphery provides a repressive compartment like the nuclear
343 lamina(Kind and van Steensel 2010). We previously found that LINE1 RNA and repressors Kap1 and
344 Ncl bind both *Dux* and rDNA in ESCs(Percharde et al. 2018) with a recent report also identifying
345 nucleolar Lin28 as a *Dux* repressor within this complex(Sun et al. 2021). Furthermore, it is likely that
346 other repressor proteins may colocalise at the nucleolar periphery. For example, the histone

9

347 methyltransferase, G9a has been reported in the nucleolus(Yuan et al. 2007), while a repressive role

348 for nucleolar RNA Pol II itself has been recently discovered(Abraham et al. 2020).

349

350 In addition to *Dux* regulation, our work points to a wider role for nucleolar chromatin in gene regulation

351 and its dynamic establishment in early embryos. RNA-seq data upon iPol I suggests that genes within

352 Type II NADs, regions which are only associated with nucleoli and not constitutive LADs, are most

353 sensitive to nucleolar disruption. In contrast, Type I NADs that show both nucleolar and constitutive

354 lamina association are not upregulated upon acute iPol I, in agreement with their classification as

355 constitutive heterochromatin and their low expression(Vertii et al. 2019; Bizhanova et al. 2020).

356 Towards this, HDL treatment in MEFs was shown to cause relocalisation of a Type II, but not Type I,

357 NAD(Vertii et al. 2019). Future work is needed to understand if these distinct NAD classes show

358 differences in their association strength with the nucleolus, or if their activation depends on further

359 mechanisms or factors upon dissociation. For example, neuronal NAD genes detach from the nucleolus

360 upon neural progenitor cell differentiation yet do not yet become activated, supporting the model that

361 their release might poise them for later expression(Bersaglieri et al. 2020).

362

363 More broadly, it will be important in future work to understand how nucleolar chromatin organisation

364 proceeds in early embryos, as well as to uncover which genes rely on nucleolar association for their

365 repression. Together with new findings of nucleolar function/dysfunction in multiple processes such as

366 protein quality control(Azkanaz et al. 2019; Frottin et al. 2019), cancer(Lindstrom et al. 2018) and

367 aging(Buchwalter and Hetzer 2017; Tiku and Antebi 2018), our data reveal a novel axis of nucleolar

368 biology in early development and reflect the multi-faceted function of the nucleolus.

Materials and Methods

Mice and embryos

All animal experiments were performed according to a UK Home Office Project Licence in a Home Office-designated facility, using 4-6-week old female and 2-6-month-old male CD1 mice (Charles River). Animals were maintained on a 12h light/dark cycle and provided with *ad libitum* food and water in individually ventilated cages. Female mice were superovulated by intra-peritoneal injection of 5 I.U of pregnant mare serum gonadotropin (PMSG, Folligon, MSD Animal Health), followed by 5 I.U of human chorionic gonadotropin (hCG, Chorulon, MSD Animal Health) 46-48h later, then placed immediately with males. Zygotes were collected from oviducts ~22-24h post-hCG in M-2 medium (Sigma, M7167), isolated from cumulus cells with 200μg/mL Hyalurionidase (Sigma, H3506), washed through successive drops of M-2, and then cultured in pre-equilibrated KSOMaa (Sigma, MR-106-D) in microdrops overlaid with mineral oil (Sigma, M5310) or in 4-well dishes. Zygotes were cultured in a humidified incubator at 37oC, 5% CO_2, until early 2-cell (31-33h post-hCG), late 2-cell (48-49h post-hCG), morula (3d post-hCG), or blastocyst (4d post-hCG).

ESC culture

Mouse E14Tg2A (E14) ESCs (male) were used for all experiments(Hooper et al. 1987) and to derive 2C-GFP reporter cells. 2C-GFP reporter ESCs are described previously(Percharde et al. 2018) and were used when prior purification of larger numbers of 2C-like cells was not needed or for validation. All ESCs were cultured at 37°C, 5% CO_2, on 0.1% gelatin-coated plates in ES-FBS culture medium (high glucose DMEM GlutaMAX with sodium pyruvate (Thermo Fisher Scientific), 15% FBS (Gibco), 0.1mM non- essential amino acids (Gibco), 0.1mM 2-Mercaptoethanol (Millipore) and 1,000U/ml LIF supplement (ESGRO, Millipore). ESCs were routinely tested for mycoplasma and found to be negative. Inhibitors (Table S2) were added to ESCs at the indicated concentrations unless otherwise explicitly mentioned in the figure legend.

2C-GFP/CD4 cell line

The 2C-GFP reporter construct(Ishiuchi et al. 2015) was modified to insert a T2A cleavage element followed by the extracellular portion of mouse CD4 (a.a.1-427) immediately downstream of GFP, so that activation of MERVL in the 2C-like state labels cells doubly positive for GFP and CD4. ESCs are negative for CD4 expression, enabling rapid purification of endogenous 2C-like cells via selection for CD4+ surface expression. E14 ESCs were nucleofected with 4ug linearized 2C-GFP plasmid and plated at low density in 10cm^2 plates then selected with 250 μg/mLG418 (Mirus) for 8 days. Individual colonies were picked and expanded, with a single colony that showed high specific expression of GFP expanded and used for subsequent validations and experiments. For 2C-GFP/CD4 isolation, cells were trypsinised, washed, and resuspended in FACS buffer (PBS, 3% FBS, 1mM EDTA) then either isolated by MACS, using CD4 (L3T4) microbeads (Miltenyi Biotec), or with the EasySep mouse CD4 Positive selection kit II (StemCell), according to the manufacturer's protocols in each case. Apart from Figure S1, all purification experiments were performed with the EasySep kit. Flow-through cells were collected

409 as the 2C-negative population. For flow cytometry analysis, ESCs were pelleted and resuspended in
410 FACS buffer containing 1:8000 Sytox Blue (Thermo Fisher Scientific) to enable exclusion of dead cells.
411

412 **siRNA-mediated knockdown**
413 The nucleolar miniscreen was performed with a Cherry Pick custom library plate of OnTargetPlus
414 siRNAs (Horizon Discovery), consisting of 20 wells of different gene-targeting siRNA pools and 3
415 siControl wells. 2C-GFP ESCs (non-CD4) at a density of 10,000 cells per 96-well were transfected in
416 suspension with 3pmol siRNA and 0.17uL Lipofectamine 2000 per well of a 96-well plate and incubated
417 overnight. The media was changed the following day then cells cultured for a further 2 days before
418 analysis. For flow cytometry, ESCs were trypsinised, transferred to a 96-well, round-bottom plate,
419 pelleted, washed and then resuspended in PBS plus 1:8000 Sytox Blue (Thermo Fisher Scientific), then
420 the %GFP in live cells analysed by flow cytometry on a BD Fortessa cytometer. The nucleolar
421 miniscreen was performed in triplicate wells and the entire experiment repeated on a different day with
422 highly similar results. Z-scores were calculated as the %2C-GFP value for each factor minus the
423 average 2C-GFP level for the entire plate, divided by the plate standard deviation. Other siRNA
424 transfections or validation experiments were performed as above, scaling up cell numbers,
425 Lipofectamine and siRNA amounts accordingly for ESCs cultured in 12- or 24-well plates, with cells
426 harvested at the indicated time points.
427

428 **Nascent transcription/translation assays**
429 Nascent transcription (EU) and translation (HPG) assays were carried out as described
430 previously(Percharde et al. 2018) using Click-iT Assay Kits (Thermo Fisher Scientific) and according to
431 the manufacturer's protocol. For HPG assays, ESCs were cultured in medium made with DMEM lacking
432 methionine (Gibco, #21013024) for 1h prior to HPG addition. ESCs were cultured with 1 mM EU or 50
433 uM HPG for 45 min before fixation, permeabilization and Click-iT reaction. Where indicated,
434 immunofluorescence labelling was carried out prior to Click-iT as described above with the exception
435 that primary antibodies were added for 1-2h at RT.
436

437 **Western blotting**
438 Whole cell extracts were prepared from ESCs by scraping in ice-cold RIPA buffer containing protease-
439 inhibitors (Halt), incubating for 30 min at 4°C, then pelleting at 16000g, 20 min to remove insoluble
440 material. Proteins were quantified by the BCA assay (Pierce) and equal amounts loaded onto 4-12%
441 Bolt Bis-Tris plus SDS-PAGE gels (Thermo Fisher) to separate proteins, then transferred onto PVDF
442 membranes. Blocking was performed in 5% milk/PBS-T for 1h then membranes incubated overnight
443 with primary antibodies at 4oC in milk/PBS-T. Next day, membranes were incubated with the
444 appropriate HRP-conjugated secondary antibodies (Cell Signaling) for 1h, then proteins detected by
445 ECL reagent on an Amersham Imager 680.
446

447 **RNA Extraction and Expression Analysis**

448 RNA was isolated directly from ESCs by scraping in RLT lysis buffer (Qiagen) containing 1:100 beta-
449 mercaptoethanol (Sigma), or RLT was added to equal numbers of ESCs for CNN approaches. RNA
450 was purified and DNAse I treated according to the manufacturer's instructions using RNeasy mini kits
451 (Qiagen). For embryo inhibitor experiments, 2-cell embryos were flushed at 46h post-hCG and cultured
452 in KSOMaa medium containing either 1μM CX-5461, BMH-21, or 0.1% DMSO in a 4-well dish. Culture
453 in inhibitors began after 1h for a period of 8 or 24 hours. Equal numbers of embryos per experimental
454 condition were lysed in 75 μL buffer RLT prepared as above, and the RNA isolated according to RNeasy
455 micro kits (Qiagen). In ESCs and embryos, cDNA synthesis was performed with up to 1μg DNase-
456 treated RNA using a High Capacity RNA-to-cDNA kit (Thermo Fisher Scientific), and qRT-PCR
457 performed with SYBR green (KAPA) on a QuantStudio 5 qPCR machine (Thermo Fisher Scientific).
458 qRT-PCR data were normalised to two housekeeping genes (Rpl7/H2A), unless a cell-number-
459 normalisation (CNN) approach was used as detailed in the legend. Primer sequences are described in
460 Table S2.

461

462 **RNA-sequencing and Analysis**
463 For RNA-seq, RNA was extracted utilizing the RNeasy mini kit as for qRT-PCR, then 3 biological
464 replicates per condition of DNase-treated total RNA spiked with ERCCs (Thermo Fisher) was used for
465 RNA-seq library preparation and sequencing at the MRC LMS genomics core facility. RNA quality was
466 assessed using the Agilent 2100 RNA 6000 Nano assay and libraries were prepared using the NEBNext
467 Ultra II Directional RNA Library Prep Kit with NEBNext Poly(A) mRNA Magnetic Isolation Module,
468 following manufacturer's instructions. Library quality was evaluated using the Agilent 2100 High-
469 Sensitivity DNA assay, and their concentrations measured using the Qubit™ dsDNA HS Assay Kit.
470 Libraries were pooled in equimolar quantities and sequenced on an Illumina NextSeq 2000 to generate
471 a minimum of 40 million Single Read 50bp reads (with unique 8bp dual indexes) per sample. Reads
472 were trimmed and aligned to reference genome mm10 plus ERCCs using Tophat2. Default settings
473 were used apart from the specification 'g -1' to map each multimapping read to one random TE or gene
474 in the genome. Reads were counted using the Subread package, FeatureCounts to each gene or TE
475 family. Data were filtered to exclude rows with counts per million (cpm) >0 in fewer than 3 samples. To
476 account for any global decreases in RNA amounts due to iPol I, we used our previously described cell-
477 number-normalised (CNN) approach to normalise reads to the abundance of ERCC spike-
478 ins(Percharde et al. 2017) using Limma Voom. All other RNA-seq analyses and statistics were
479 performed in R/Bioconductor. Normalised RNA-seq expression data are available in Table S1. RNA-
480 seq data have been uploaded to GEO, accession GSE185424.

481

482 For analysis of NAD gene expression, NAD regions defined in ESCs were taken from Bizhanova et al.,
483 2020(Bizhanova et al. 2020). Type I NADs (overlapping constitutive LADs) and Type II NADs
484 (overlapping constitutive interLADs) were defined as described in Vertii et al., 2019(Vertii et al. 2019)
485 using LAD data from Peric-Hupkes et al., 2010(Peric-Hupkes et al. 2010), after LAD coordinates were
486 shifted to mm10 using LiftOver tool (UCSC Genome Browser). For an example of NAD/LAD
487 classification at the *Dux* locus see Figure S7. Ranked lists of log$_2$ fold-change were prepared from RNA-

488 seq of Pol I inhibitor treated ESCs (this study) and Ncl and LINE1 knockdown ESCs(Percharde et al.
489 2018). Ranked lists and Type I and Type II NAD files were submitted to the GSEA pre-ranked tool
490 (genepattern.org) with the following parameters: permutations = 10000, collapse dataset =
491 No_Collapse, and max gene set size = 4000. Normalised enrichment score (NES) and false discovery
492 rate q-value (FDR) for each RNA-seq dataset were plotted using R/ggplot2.

493

494 **ESC Immunofluorescence**
495 ESCs were allowed to adhere to Matrigel-coated 8-well chambers or 10 mm glass coverslips for 1-2h,
496 fixed in 4% PFA for 10min, then stored in PBS until staining. Blocking and permeabilization was carried
497 out in one step in immunofluorescence (IF) buffer (PBS, 10% donkey serum, 2.5% BSA), plus 0.4%
498 Triton X-100 for 30min. Primary antibody incubations were carried out overnight at 4°C using the
499 indicated antibodies and dilutions in IF buffer in Table S2. Next day, samples were washed with PBS
500 and incubated in secondary antibodies (1:500 Alexa-488nm, 594nm, or 647nm- conjugated antibodies)
501 for 1h at RT, followed by a wash for 30 min in PBS plus DAPI, two more washes in PBS, then samples
502 mounted in Vectashield mounting medium containing DAPI. Confocal images were taken on a Leica
503 SP5 fluorescent microscope under an oil immersion 63X objective.

504

505 **Embryo in vitro culture EU/HPG and IF experiments**
506 Embryos were fixed in 4% PFA in PBS containing 0.1% Triton X-100 for 30 min, followed by three
507 washes in PBS containing 0.1% PVA (PBS-PVA). Samples were permeabilised in PBS containing 0.5%
508 Triton X-100 for 30 minutes, followed by blocking in 5% BSA in PBS for 1.5 hours. A 1:100 dilution of
509 primary antibody (rabbit anti-nucleolin, Abcam, ab22558) was prepared in blocking solution, and
510 embryos were incubated in 10 µl drops in a humidified Terasaki plate (Greiner Bio-One) at 4°C
511 overnight. Embryos were washed three times in PBS containing 0.1% Tween-20 and 0.1% PVA (PBST-
512 PVA) for five minutes. A 1:500 dilution of secondary antibody (donkey anti-rabbit Alexa Fluor 488,
513 ThermoFisher, A21206) was prepared in blocking solution, and embryos were incubated in 10 µL drops
514 in a humidified Terasaki plate for 1h in the dark. EU and HPG assays were performed as for ESCs,
515 except that embryos were incubated for 1h in pre-equilibrated KSOM (without amino acids; Millipore),
516 prior to incubation in KSOM containing 500 µm HPG or 1 mM EU for 2h. Embryos were fixed in 4%
517 PFA in PBS containing 0.1% Triton X-100 for 15 minutes, and permeabilised in 0.5% Triton X-100 in
518 PBS for 20 minutes, prior to Click-iT reactions. Prior to mounting, all samples were washed three times
519 in PBST-PVA for five minutes, followed by a 30 min incubation in 1:1000 DAPI in PBS, and a further
520 three washes in PBS-PVA. Embryos were mounted in Vectashield (Vector Laboratories) under a
521 20x20mm #1.5 coverslip (Agar Scientific) supported at the corners by Dow Corning high-vacuum
522 silicone grease (Sigma-Aldrich) and sealed with nail polish. Confocal images were captured using a
523 Leica SP5 or SP8 fluorescence microscope using an oil immersion 40X objective and acquired in 1 µm
524 Z-stacks. All steps were carried out in 500 µl volumes at room temperature unless otherwise noted.

525

526 **Single Molecule RNA FISH combined with immunofluorescence staining (Immuno-smRNA-**
527 **FISH)**

14

528   *Dux* smRNA-FISH was based on branched DNA technology

529   (*https://www.thermofisher.com/uk/en/home/life-science/cell-analysis/cellular-imaging/in-situ-*

530   *hybridization-ish/rna-fish.html*) *to* detect the dynamics of *Dux* expression upon the inhibition of

531   ribosomal RNA synthesis. A target set of 20 short Alexa647 labelled oligo mouse *Dux* ViewRNA ISH

532   probe (VB6-3223670-VC, type-6; ThermoFisher Scientific) was designed and used to hybridize to *Dux*

533   RNA sequence. Cells were first adhered on Matrigel-coated 10 mm glass coverslips and fixed with 4%

534   paraformaldehyde in DEPC-treated PBS, containing 2.5% Acetic acid for 10 mins. Immunolabeling with

535   performed with mouse anti-B23 primary antibody (1:300; 2h) then detected with Alexa 488 donkey anti-

536   mouse antibody (Invitrogen; 1:500; 1h), then further fixed with 4% paraformaldehyde in DEPC-PBS, 10

537   min to preserve immunocomplexes before FISH. smRNA FISH was carried out in accordance with the

538   manufacturer's protocol for the ViewRNA ™ ISH Cell Assay (QVC001; ThermoFisher Scientific). Briefly,

539   previously immunolabled cells were washed in PBS (3x), permeabilised (1:2 digestion solution in

540   DEPC-PBS; 5 min), protease treated (1:8000 in DEPC-PBS, 10 min), and subsequently hybridized with

541   Alexa 647 ViewRNA ISH *Dux* probe (P4, 1:100 in QF diluent; 3h, 40°C). Following probe hybridisation,

542   cells were washed and then subjected to sequential hybridisation with pre-amplifier DNA, amplifier DNA

543   and fluorophore labeled in provided diluent (1:25, 1h, 40°C each step). After detection, cells were

544   washed and nuclei were stained with 1μg/ml DAPI in PBS before imaging. Control experiments were

545   performed with either hybridisation with mouse B-actin probe as a positive control that revealed

546   abundant b-actin RNA foci throughout nucleus and cytoplasm, or Rnase A treatment (250 μg/ml in PBS,

547   2h, 37oC) prior to hybridisation, which abrograted *Dux* signals.

548

549   **DNA FISH with immunofluorescence (Immuno-DNA-FISH)**

550   Immunofluorescence detection of nucleolus and nuclear lamina combined with DNA was performed

551   essentially as described previously(Beagrie et al. 2017). Briefly, ESCs were fixed with 4% plus 0.1%

552   Triton in PBS, 10 min, washed in PBS (3x), equilibrated in 20% glycerol in PBS (3x, 10min),

553   subsequently then frozen in liquid nitrogen and stored at -80°C. After thawing, cells were washed in

554   PBS 3x, permeabilized for 10 min with 0.1% triton in PBS and blocked with 2% BSA-PBS, 30 min,

555   before immunolabeling. Cells were incubated with the indicated mouse anti-B23 as above; and rabbit

556   anti-laminB1 (1:2000; ab16048; Abcam) antibodies in 2% BSA in PBS for 2h, then detected with

557   AlexaFluor488 or 647-conjugated antibodies. After immunolabelling, cells were fixed with 4% PFA in

558   PBS for 30 min prior to FISH to preserve immunocomplexes during FISH. *Dux* oligo probes used to

559   detect *Dux* foci were used and labelled with Cy3 fluorphores (PA23001; Amersham) as described

560   previously (Percharde et al. 2018). For hybridisation, 1 μg mouse Cot1 DNA (18440; Invitrogen), 10 μg

561   salmon sperm DNA (15632011; Invitrogen) and 3 μl Cy3- labelled Dux oligos, respectively, were

562   precipitated and resuspended in 6 μl of hybridisation buffer (H7782, Sigma-Aldrich) ready for DNA

563   FISH. Immunolablled cells were rinsed 3x in PBS, incubated for 15 min in 20 mM glycine in PBS, rinsed

564   3x in PBS, permeabilised for 10 min with 0.2% Triton, and then washed again. Cells were incubated for

565   1-2h at 37°C with 250 μg/ml RNase A (Sigma) in 2x SSC, treated for 10 min with 0.1 M HCl, dehydrated

566   in ethanol (50% to 100% series, 3 min each), dried briefly, denatured for 10 min at 80°C in 70%

567   deionized formamide in 2xSSC, and then re-dehydrated as above. After a brief period of drying,

15

568 coverslips were overlaid onto probe mixture on Hybrislips (H18200; Molecular Probe by Life
569 Technology) and sealed with Fixogum rubber cement (11FIXO0125; MP Biomedicals) for in situ
570 hybridisation. Hybridization was carried out at 37°C in a moist chamber for at least 40 h. Post-
571 hybridization washes were as follows: 40% formamide in 2xSSC (3x 10min); 2xSSC (3x, 10min); and
572 (3x, PBS). Nuclei were counterstained with 1μg/ml DAPI in PBS for 30 min and mounted in (Vectashield
573 H-1000; Vector Laboratories) immediately prior to imaging.

574

575 **Super-Resolution Structured Illumination Microscopy (SIM)**
576 Purified 2C-GFP/CD4-negative and positive cells or wild-type ESCs incubated for 8h with or without
577 iPol I were adhered on Matrigel-coated μ-Slide 8 Well Glass Bottom (80827; Ibidi) and fixed with 4%
578 paraformaldehyde in PBS for 10 min then stored in PBS at 4°C before immunolabeling. Cells were
579 rinsed 3x in PBS, incubated for 15 min in 20 mM glycine in PBS, rinsed, permeabilized with 0.1% Triton
580 X-100 for 10 min in PBS, blocked for 1h with 4% BSA in PBS then incubated with mouse anti-B23 to
581 detect nucleoli in 4% BSA in PBS overnight at 4°C. Next day, samples were washed 3x for 60 min with
582 2% BSA in PBS, then incubated 2h with Alexa secondary antibodies (1:250) washed again as above.
583 Finally, samples were washed and counterstained with 1μg/ml DAPI (30 min), rinsed successively in
584 PBS before coverslips were mounted in VectaShield. The long incubation times used allow for antibody
585 accessibility throughout the cells, providing the highest sensitivity for SIM imaging. Multi-colour SIM
586 imaging was performed using a Zeiss Elyra S.1 (Carl Zeiss Microimaging) and a Plan-Apochromat
587 63×/1.4 oil lens. Raw SIM images were acquired with an sCMOS camera (pco.Edge 4.2) using five
588 phase shifts and three grid rotations, with a z step size of 0.1 μm. Different fluorescent labels were
589 acquired sequentially using 642, 561, 488 and 405nm laser lines. SIM images were reconstructed with
590 ZEN 2012 SP4 (Black) software (Carl Zeiss Microimaging, version 13.0.2.518), using default parameter
591 settings. Channel alignment was performed using calibrations obtained from a multi-coloured bead
592 slide, acquired with equivalent acquisition settings.

593

594 **ESC Confocal microscopy and Quantitative Image Analysis**
595 Multi-colour image single snapshots (IF and EU/HPG assays) or Z-stacks (250nm stepsize, RNA/DNA
596 FISH) were acquired with a laser-scanning confocal microscope with a pinhole diameter of 1 Airy unit
597 (Leica TCS SP5 or SP8; Objective lens: 63x/1.40NA Oil CS2 HC PL APO; laser lines:
598 405/488/552/638nm). Different channels were imaged sequentially to avoid bleed through and cross-
599 excitation and then exported as TIFF files for further images analysis. RNA and DNA FISH image Z-
600 stacks were also acquired on an Olympus spinning disk confocal system based on an IX83 inverted
601 microscope stand (Yokogawa CSU-W1 scanhead with 50μm diameter pinhole disk; Objective lens:
602 60x/1.40NA Plan-Apo; Hamamatsu ORCA Flash 4.0 V2 camera, stepsize 200nm). Raw .lif images were
603 processed into TIFF files and merged, each channel manually thresholding or filtering with the same
604 setting in Fiji software for data analysis.

605

606 Dux FISH 3D spatial analysis was undertaken using custom written scripts in Fiji for nuclei and nucleoli
607 segmentation, and Imaris (version 9.6.0, Bitplane AG) for Dux FISH probe identification and distance

16

608 measurements. Briefly, identification of LaminB1 labelled Nuclei and B23 labelled Nucleoli was
609 performed in Fiji in combination with the MorphoLibJ plugin to perform 3D segmentation. Labelled
610 image masks generated were combined with the original image stack and imported into Imaris for use
611 with the 'Cells' Package, to facilitate interactive review of 3D segmentation results and Dux FISH probe
612 identification. Identified *Dux* FISH loci were related to each individual nucleus and contained nucleoli,
613 and distance to the nearest nucleoli and nuclei border measured.

614

615 The analysis of nucleolar morphology and fluorescence intensities was carried out with a custom written
616 CellProfiler pipeline (https://cellprofiler.org/; software version 4.1.3). To describe and quantify the
617 number of "ring-shaped" nucleoli - showing a distinct fluorescent B23 signal at the rim of the nucleoli
618 with a much dimmer interior signal – the fluorescence intensity distribution over four concentric layers
619 in each nucleolus was measured. The mean fluorescence intensity of the outer layer was divided by
620 the mean intensity of the innermost layer and any nucleolus with a ratio greater than 1.4 was counted
621 in the "ring-shaped" category. Nucleolar circularity ("Form Factor") was calculated within CellProfiler
622 according to $4\pi \times$ [Area]/[Perimeter]^2, excluding very small nucleoli which are liable to give unreliable
623 measurements (FormFactor values >1).

624

Statistical analysis

626 All statistical analyses were carried out in Prism 7 or above (Graphpad) or R (RNA-seq data). Details
627 of individual tests are outlined within each figure legend, including number and type of replication
628 performed (n) and the reported error either as standard deviation (s.d) or standard error of the mean
629 (s.e.m). All statistics are * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** $p < 0.0001$ with the relevant test
630 performed described in figure legends and corrections for multiple testing applied where necessary.
631 Welch's correction was applied to t-tests when the variance was unequal between conditions.

632

Data Availability

634 RNA-seq data have been uploaded to GEO, accession GSE185424.

635

Code Availability

637 RNA-seq data were analysed with standard packages and programs, as detailed in the Methods. Code
638 for data processing and analysis are available at https://github.com/mpercharde/RNAseq and/or are
639 available upon request.

640

Acknowledgements

648

Author Contributions

M.P. conceived the project. S.Q.X., B.J.L, P.C, F.G-L, N.T-F.C and M.P. designed and performed experiments. C.W. and D.D. performed microscopy image analysis with S.Q.X.. R.T.W. generated 2C-GFP/CD4 ESCs, supervised by M.T.M.. B.J.L and M.P. performed computational analysis. S.Q.X and M.P. wrote the manuscript with input from all authors.

850 **Figure Legends**

851

852 **Figure 1. A new reporter cell line for purification of 2C-like cells.**

853 (A) Reporter design: a previous MERVL-GFP reporter(Ishiuchi et al. 2015) is modified to contain the

854 extracellular portion of the CD4 antigen downstream of GFP and a T2A cleavage element, allowing

855 rapid 2C-like cell purification by anti-CD4 beads.

856 (B) Representative flow cytometry plot depicting proportion of typical 2C-GFP+ (2C-pos) cells before

857 (left) and after (right) CD4-based 2C enrichment.

858 (C) Percent recovery of 2C-GFP positive (pos) cells after CD4-based purification, comparing CD4+

859 cells (eluate) and CD4- cells (flow-through). Data are mean +/- s.e.m of 3 experiments.

860 (D) qRT-PCR validation of high levels of 2C-specific genes and TEs in the CD4+ eluate compared to

861 CD4- fraction and the starting population. Data are mean +/- s.e.m of 3 experiments.

862 (E) Representative confocal images and (F) quantification of levels of Oct4 and MERVL gag proteins

863 and DAPI in 2C-pos versus 2C-neg cells following CD4-based purification. Scale bar, 20 μm

864 All P values represent two-tailed, unpaired Student's t-test, with Welch correction for uneven variance

865 where relevant.

866

867 **Figure 2. 2C-like cells and embryos have altered nucleolar morphology and function.**

868 (A) Experimental set-up for 2C-like cell profiling: following CD4-based enrichment, 2C-neg/pos

869 populations are plated into Matrigel-coated chambers for a minimum of 1h before the indicated

870 downstream applications.

871 (B) Immunofluorescence images and quantification (RingShape+, CellProfiler) appearance in 2C-

872 pos/neg cells, revealing that 2C-like cell nucleoli, stained by the nucleolar marker B23 (Npm1), have

873 rounded, ring-like morphology, n, number of nucleoli scored. Scale bar, 20 μm.

874 (C) Nucleolar circularity is significantly increased in 2C-like cells. Very small nucleoli (area <100 pixels)

875 were filtered out as can typically generate unreliable measurements (see methods).

876 (D-E) Immunofluorescence images and quantification of (D) nascent translation and (E) nascent

877 transcription rates in 2C-pos versus 2C-neg cells via HPG or EU Click-iT incorporation

878 experiments, respectively. Scale bar, 25 μm.

879 (F) Confirmation of reduced transcription and translation in 2C-like (2C-GFP+) cells within unsorted

880 populations, using an independent 2C-GFP cell line(Percharde et al. 2018). Scale bar, 10 μm.

881 (G) Nucleolar (Nucleolin, Ncl) staining in in vitro cultured embryos, showing the emergence of Ncl+

882 nucleoli at the late 2-cell stage (L2C). PN5, zygote PN5 stage, E2C, early 2-cell stage; PB, polar

883 body. Scale bar, 20 μm

884 (H) Analysis of nascent transcription/translation in embryos by EU/HPG assays. Scale bar, 20 μm.

885 Insets show EU/HPG staining alone (grayscale) in a representative blastomere from each image.

886 P values represent (B) Chi-squared test and (C, D-E) two-tailed Student's t-test, with Welch's correction

887 for uneven variance where relevant.

888

889 **Figure 3. Nucleolar disruption induces the 2C-like state.**

23

(A) Representative immunofluorescence images following staining for nucleolar markers (Fibrillarin, Fbl) and B23 4h after RNA Pol I inhibition (iPol I), with either CX-5461 or BMH-21. Scale bar, 20 µm.

(B) Quantification of the percentage of ring-like (RingShape+) nucleoli 4h after iPol I. P values, Chi-squared test; n, number of nucleoli.

(C) Percentage of 2C-GFP+ cells following overnight (16-24h) treatment with 0.25 µM iPol I, data are mean +/- s.e.m, n=3 biological replicates representative of 3+ experiments.

(D) qRT-PCR analysis of 2C-specific genes and TEs following iPol I as in (C), with P values in (C-D) representing 2-tailed t-test with two-stage multiple comparisons correction.

(E) Western blots showing upregulation of 2C-specific proteins, Zscan4 and MERVL gag, after 16-24h iPol I in ESCs. Replicates from two experiments are shown.

(F) Flow cytometry analysis of % 2C-GFP+ cells following siRNA knockdown of the indicated factors. Red samples indicate a Z-score of >1, with KD of Ncl shown as a positive control (teal). Data are mean +/- s.e.m of 3 biological replicates, representative of two repeats of the screen.

(G) Validation by qRT-PCR of siRNA-mediated knockdown of the indicated factors and

(H) upregulation of 2C-specific genes, showing mean +/- s.e.m of n=2-3 biological replicates, representative of 2 experiments. P values, 2-way ANOVA followed by Dunnett's multiple comparisons test.

Figure 4. Nucleolar disruption causes *Dux* reactivation in ESCs and embryos.

(A) Cell-number normalised (CNN) qRT-PCR time course analysis of *Dux* upregulation following iPol I. Data are analysed as CNN to exclude potential global effects of iPol I on transcription; however the same results are seen with *Rpl7/H2A* normalisation. Data are mean +/- s.e.m, n=3 biological replicates. P values, two-way ANOVA and Šídák multiple comparisons test.

(B) Boxplot of log2-fold change values for n=99 *Dux* target genes(Percharde et al. 2018) versus significantly altered non-targets (FDR <0.05, n=8057: CX-5461, n=13830: BMH-21) following 8h iPol I. P values, two-sided Wilcoxon rank-sum test.

(C) Heatmap of 2C-specific genes(Macfarlan et al. 2012) showing gradual upregulation following iPol I. Samples are grouped by unsupervised hierarchical clustering.

(D-E) Expression of (D) *Dux* and (E) 2C-specific genes or a negative control (IAPEz) in iPol I rescue experiments with control or *Dux* siRNAs. Data are mean +/- s.e.m of two independent cell lines, representative of 2 experiments.

(F) Schematic for embryo iPol I inhibitor experiments with 1 µM BMH-21 or CX-5461.

(G) CNN qRT-PCR expression data following 8h iPol I in mid 2-cell embryos showing inhibited *Dux* repression. Data are mean +/- s.e.m, n=4 experiments with equal numbers of embryos, with levels at 0 h set to 1 in each experiment. P values, 1-way ANOVA with Dunnett multiple comparisons correction.

(H) CNN qRT-PCR expression data showing *Dux* upregulation after 24h 1 µM CX-5461. Data are mean +/- s.e.m n=4 experiments. P values, Welch's two-tailed t-test.

929 (I) Embryo progression rates following 24h iPol I treatment in n=4 experiments (CX-5461) and n=2
930   experiments (BMH-21). P values, Chi-squared test, n=number of embryos.

931

932 **Figure 5. Nucleolar disruption induces *Dux* relocalisation and activation**

933 (A-B) Example images of chromatin distribution as marked by DAPI staining in 3D-SIM imaging
934   experiments in (A) 2C-pos versus 2C-neg cells and (B) in ESCs upon 8h iPol I. 2C-neg cells
935   and (B) control but not iPol I ESCs have nucleolar chromatin fibres, visible as a
936   roughened nucleolar border (orange arrows, inset). Scale bar, 5 μm.

937 (C) Representative immuno-DNA FISH images at the indicated timepoints of iPol I for *Dux* alleles (red)
938   compared to nucleolar (B23, magenta) or nuclear lamina (LaminB, green) compartments. Scale
939   bar, 10 μm.

940 (D) Quantification of *Dux* localisation at 4h iPol I showing movement away from the nucleolus, P values,
941   Chi-squared test. N, number of loci

942 (E) Dotplot of GSEA enrichment scores (NES) and significance (FDR) for Type I or Type II NADs using
943   expression data following iPol I, or following LINE1/Ncl KD (Percharde et al. 2018).

944 (F) Boxplot of log2-fold change values for Type I NADs (n=1565) or Type II NADs (n=371) versus all
945   genes at 8h iPol I. P values, two-sided Wilcoxon rank-sum test, comparing Type I/II NADs to all
946   genes.

947 (G) Immunofluorescence for nucleolar markers B23 and Fbl after the indicated times of incubation with
948   1% 1,6-hexanediol (HDL), with or without washout and recovery in normal media, and (below)
949   quantification of the percentage of RingShape+ nucleoli (n), scale bar, 20 μm. P values, Chi-
950   squared test with Bonferroni adjustment for multiple comparisons.

951 (H) Scoring of *Dux* loci nuclear positioning following HDL treatments from *Dux* immuno-FISH
952   experiments; n, number of loci from two FISH experiments. P values, Chi-squared test, with
953   Bonferroni adjustment for multiple comparisons.

954 (I) Expression of *Dux* by qRT-PCR following HDL treatment, data are mean +/- s.e.m for n=3 biological
955   replicates, representative of two independent experiments. P values, one-way ANOVA with Dunnett
956   correction for multiple comparisons.

957

958 **Figure 6. A model for nucleolar-based Dux and 2C-state repression**

959 Nucleolar maturation allows for Dux repression and 2-cell exit. In early embryos and 2C-like cells, NPBs
960 have altered morphology, reduced function and reduced chromatin association. We propose this
961 provides a permissive environment for *Dux* and subsequent 2C/MERVL expression. In mature nucleoli
962 with high rRNA output, *Dux* is recruited to perinucleolar chromatin and is repressed. Disruption of
963 nucleolar integrity via iPol I or inhibition of nucleolar phase separation releases *Dux* and leads to its de-
964 repression.

Figure 1

Xie et al

Figure 1. A new reporter cell line for purification of 2C-like cells.

(A)   Reporter design: a previous MERVL-GFP reporter[31] is modified to contain the extracellular portion of the CD4 antigen downstream of GFP and a T2A cleavage element, allowing rapid 2C-like cell purification by anti-CD4 beads.

(B)   Representative flow cytometry plot depicting proportion of typical 2C-GFP+ (2C-pos) cells before (left) and after (right) CD4-based 2C enrichment.

(C)   Percent recovery of 2C-GFP positive (pos) cells after CD4-based purification, comparing CD4+ cells (eluate) and CD4- cells (flow-through). Data are mean +/- s.e.m of 3 experiments.

(D)   qRT-PCR validation of high levels of 2C-specific genes and TEs in the CD4+ eluate compared to CD4- fraction and the starting population. Data are mean +/- s.e.m of 3 experiments.

(E)   Representative confocal images and (F) quantification of levels of Oct4 and MERVL gag proteins and DAPI in 2C-pos versus 2C-neg cells following CD4-based purification. Scale bar, 20 μm

All P values represent two-tailed, unpaired Student's t-test, with Welch correction for uneven variance where relevant.
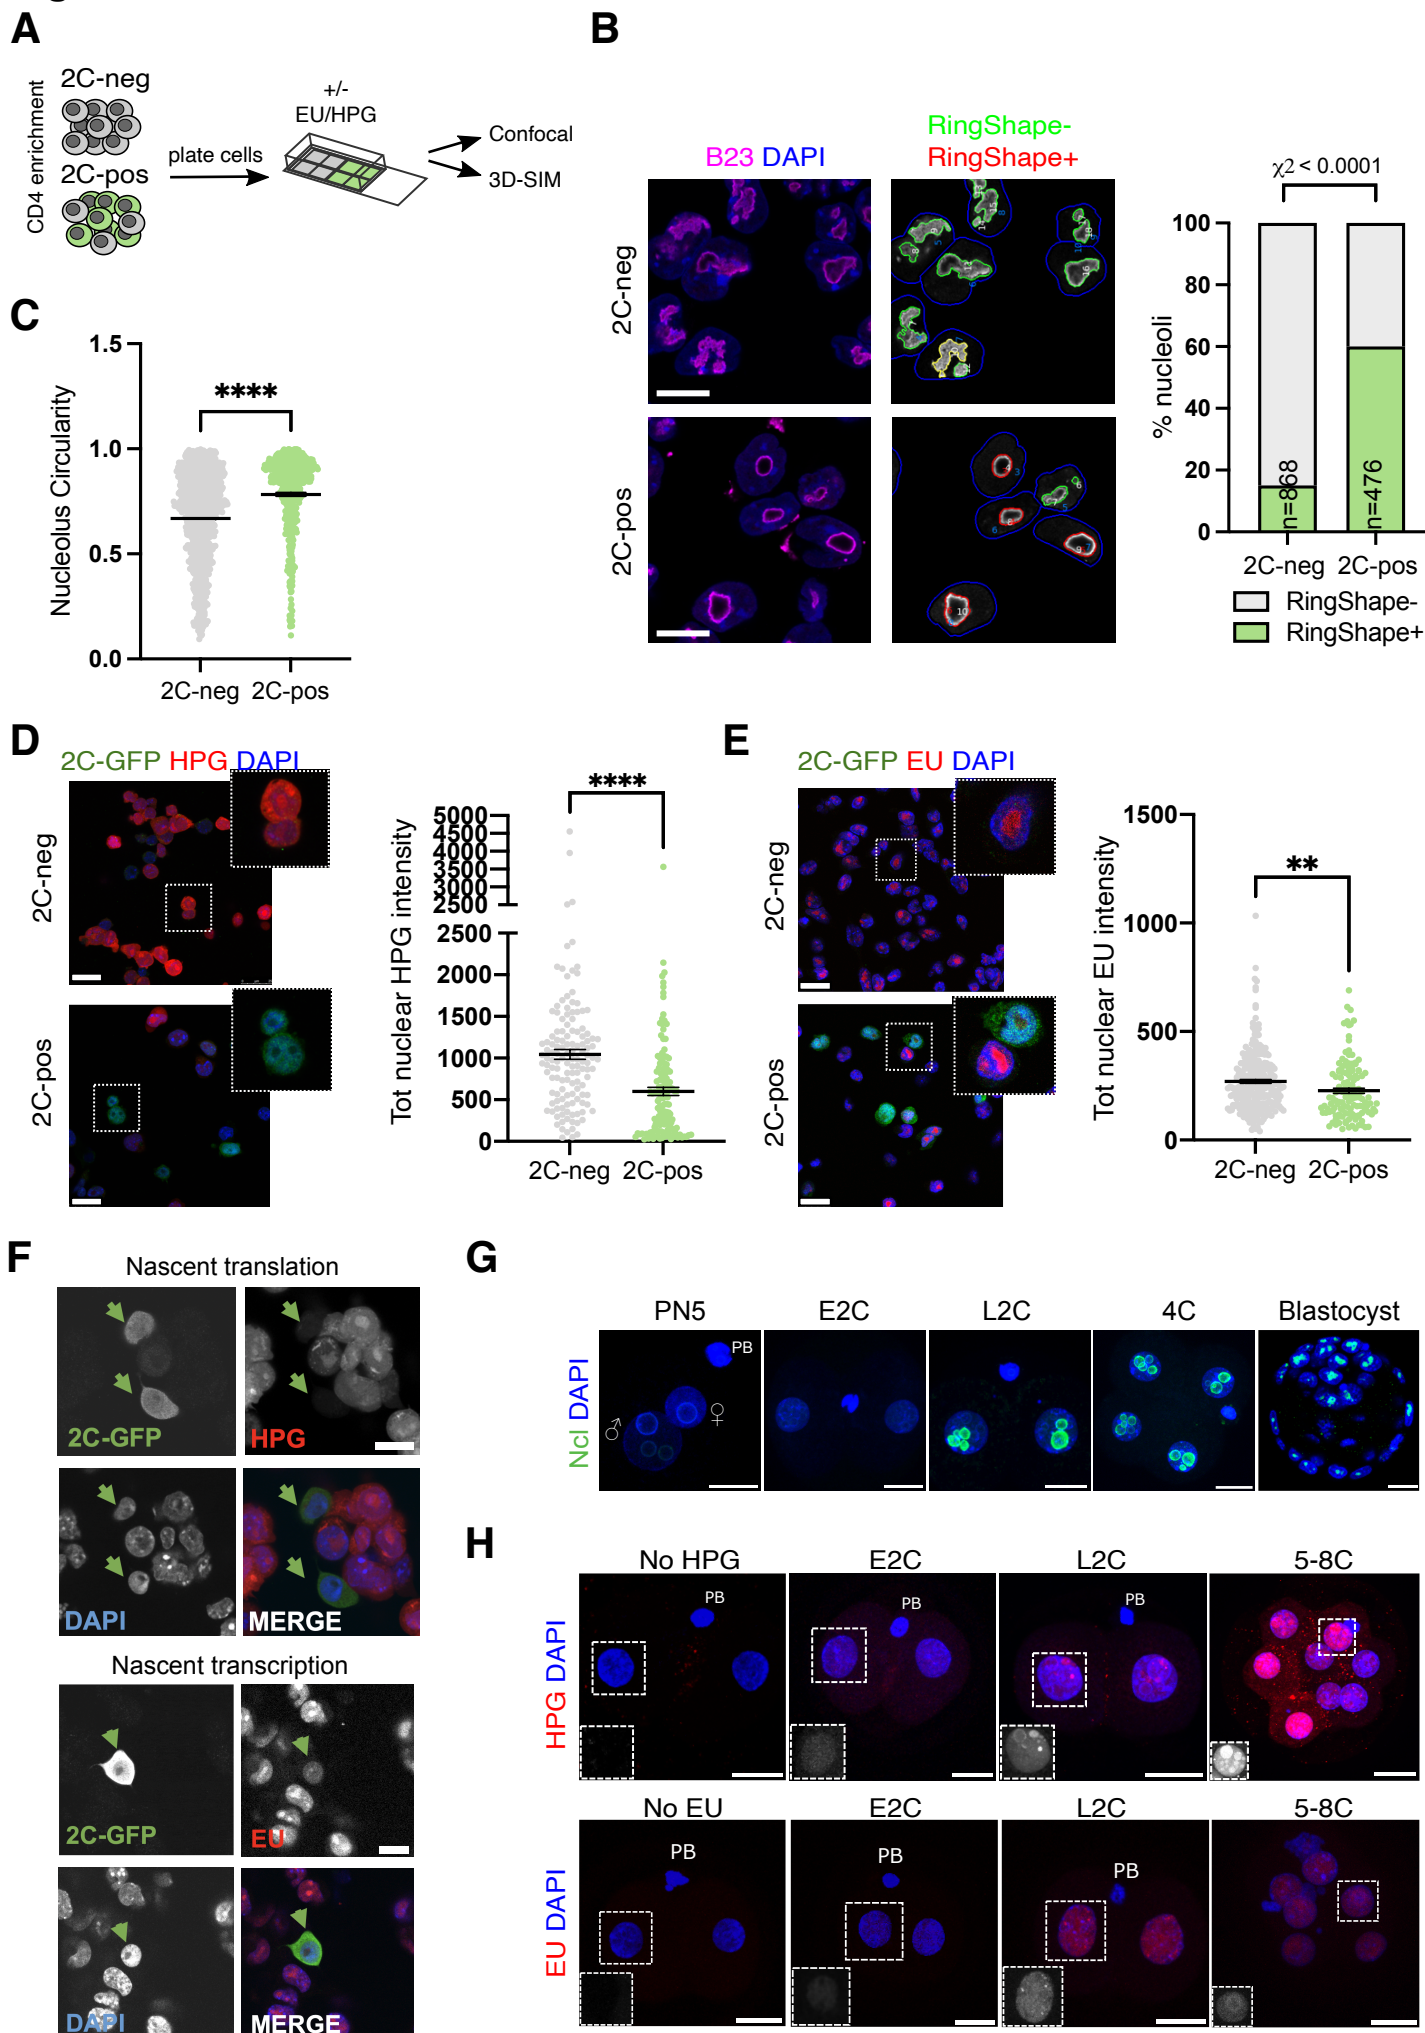

Figure 2

Xie et al

Figure 2. 2C-like cells and embryos have altered nucleolar morphology and function.

(A) Experimental set-up for 2C-like cell profiling: following CD4-based enrichment, 2C-neg/pos populations are plated into Matrigel-coated chambers for a minimum of 1h before the indicated downstream applications.

(B) Immunofluorescence images and quantification (RingShape+, CellProfiler) appearance in 2C-pos/neg cells, revealing that 2C-like cell nucleoli, stained by the nucleolar marker B23 (Npm1), have rounded, ring-like morphology, n, number of nucleoli scored. Scale bar, 20 μm.

(C) Nucleolar circularity is significantly increased in 2C-like cells. Very small nucleoli (area <100 pixels) were filtered out as can typically generate unreliable measurements (see methods).

(D-E) Immunofluorescence images and quantification of (D) nascent translation and (E) nascent transcription rates in 2C-pos versus 2C-neg cells via HPG or EU Click-iT incorporation experiments, respectively. Scale bar, 25 μm.

(F) Confirmation of reduced transcription and translation in 2C-like (2C-GFP+) cells within unsorted populations, using an independent 2C-GFP cell line[30]. Scale bar, 10 μm.

(G) Nucleolar (Nucleolin, Ncl) staining in in vitro cultured embryos, showing the emergence of Ncl+ nucleoli at the late 2-cell stage (L2C). PN5, zygote PN5 stage, E2C, early 2-cell stage; PB, polar body. Scale bar, 20 μm

(H) Analysis of nascent transcription/translation in embryos by EU/HPG assays. Scale bar, 20 μm. Insets show EU/HPG staining alone (grayscale) in a representative blastomere from each image.

P values represent (B) Chi-squared test and (C, D-E) two-tailed Student's t-test, with Welch's correction for uneven variance where relevant.
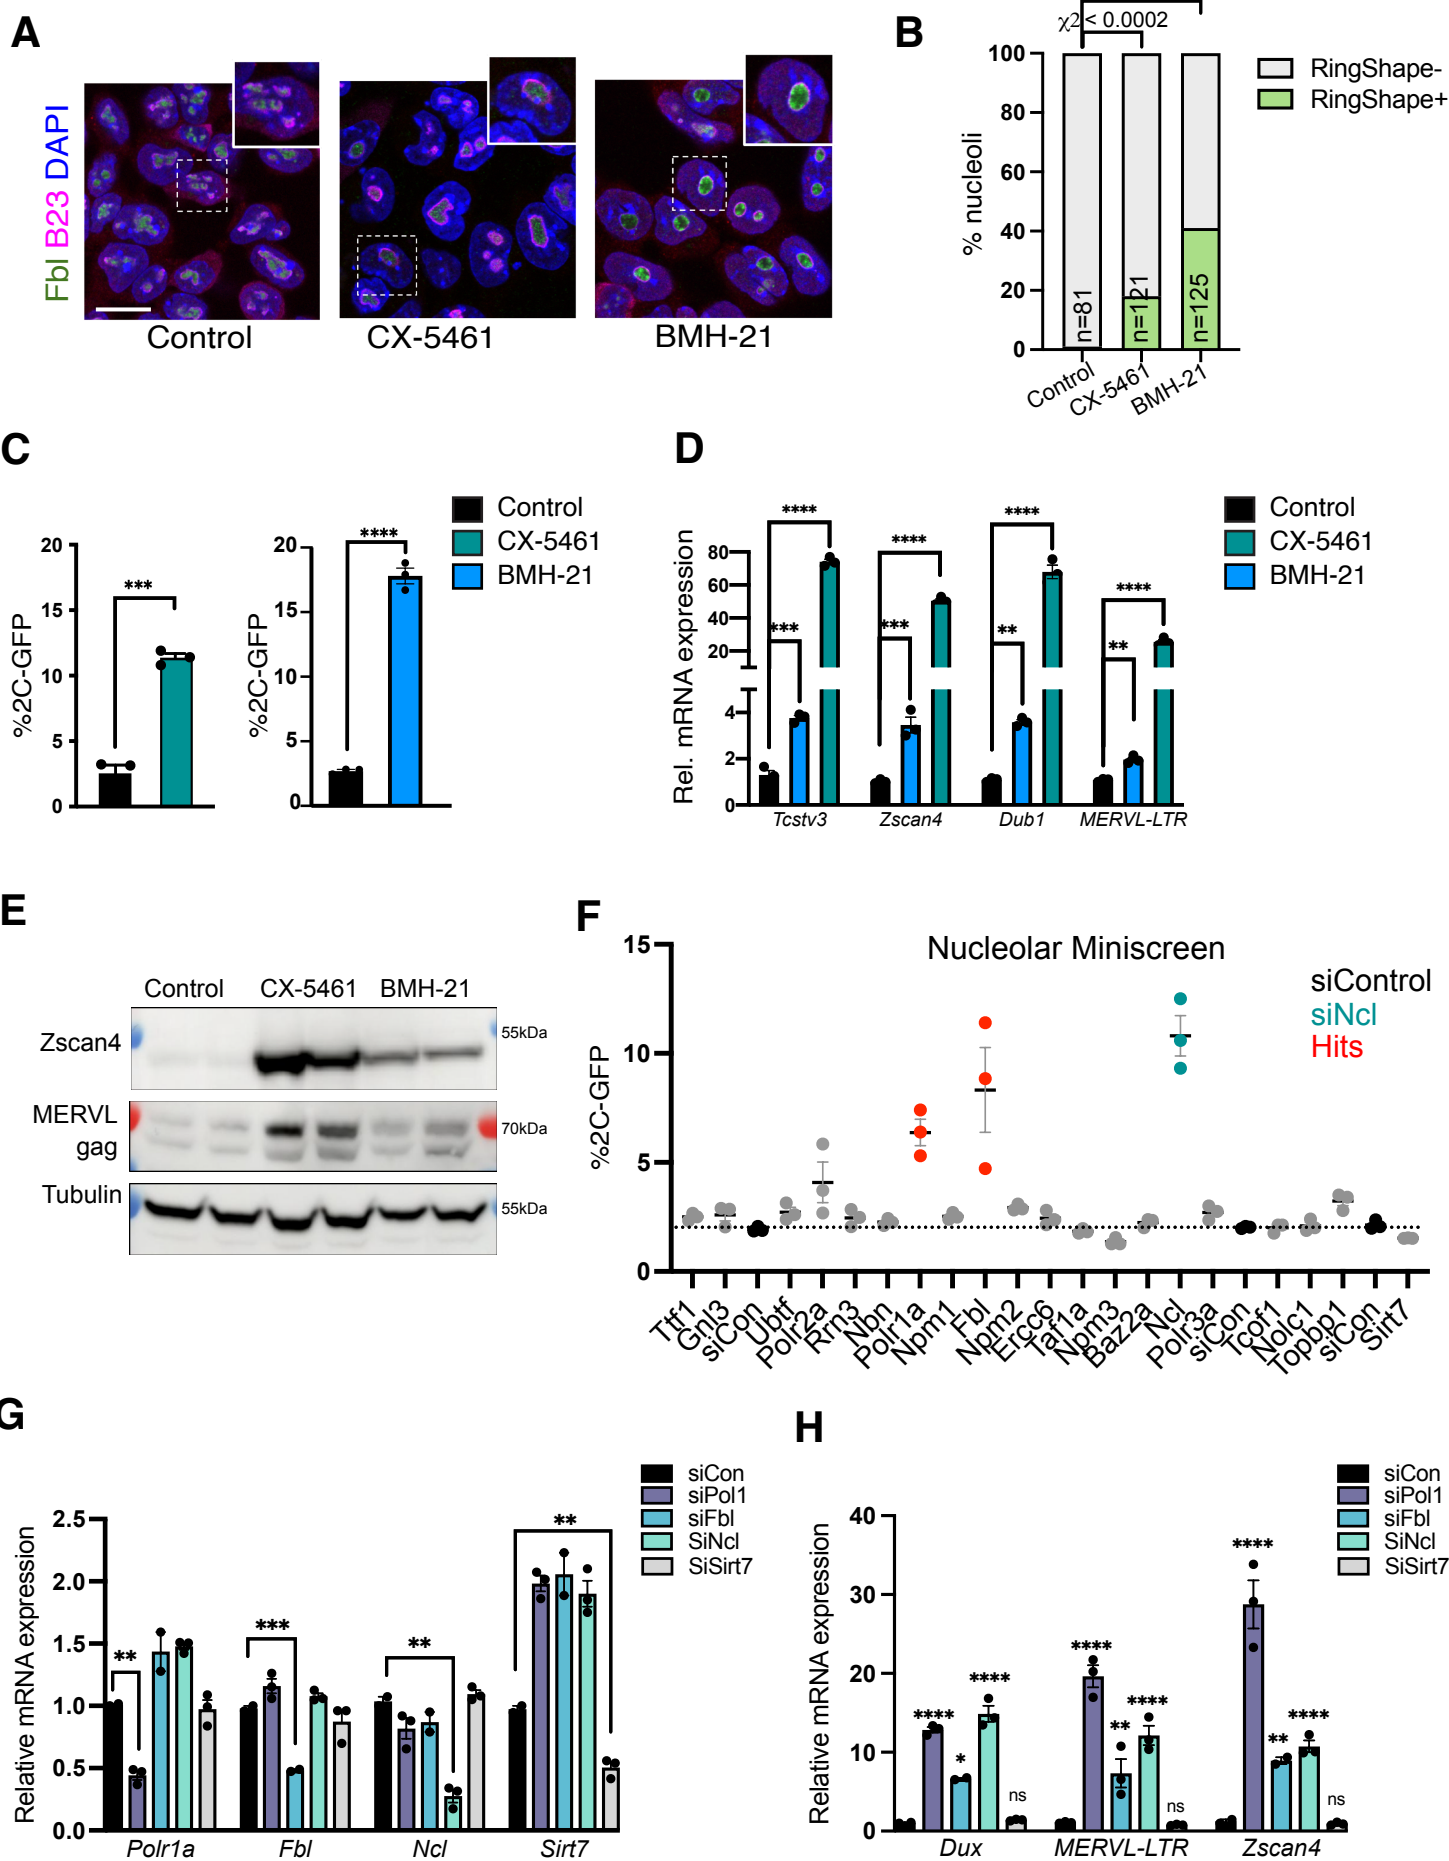

Figure 3

Xie et al

Figure 3. Nucleolar disruption induces the 2C-like state.

(A) Representative immunofluorescence images following staining for nucleolar markers (Fibrillarin, Fbl) and B23 4h after RNA Pol I inhibition (iPol I), with either CX-5461 or BMH-21. Scale bar, 20 μm.

(B) Quantification of the percentage of ring-like (RingShape+) nucleoli 4h after iPol I. P values, Chi-squared test; n, number of nucleoli.

(C) Percentage of 2C-GFP+ cells following overnight (16-24h) treatment with 0.25 μM iPol I, data are mean +/- s.e.m, n=3 biological replicates representative of 3+ experiments.

(D) qRT-PCR analysis of 2C-specific genes and TEs following iPol I as in (C), with P values in (C-D) representing 2-tailed t-test with two-stage multiple comparisons correction.

(E) Western blots showing upregulation of 2C-specific proteins, Zscan4 and MERVL gag, after 16-24h iPol I in ESCs. Replicates from two experiments are shown.

(F) Flow cytometry analysis of % 2C-GFP+ cells following siRNA knockdown of the indicated factors. Red samples indicate a Z-score of >1, with KD of Ncl shown as a positive control (teal). Data are mean +/- s.e.m of 3 biological replicates, representative of two repeats of the screen.

(G) Validation by qRT-PCR of siRNA-mediated knockdown of the indicated factors and

(H) upregulation of 2C-specific genes, showing mean +/- s.e.m of n=2-3 biological replicates, representative of 2 experiments. P values, 2-way ANOVA followed by Dunnett's multiple comparisons test.
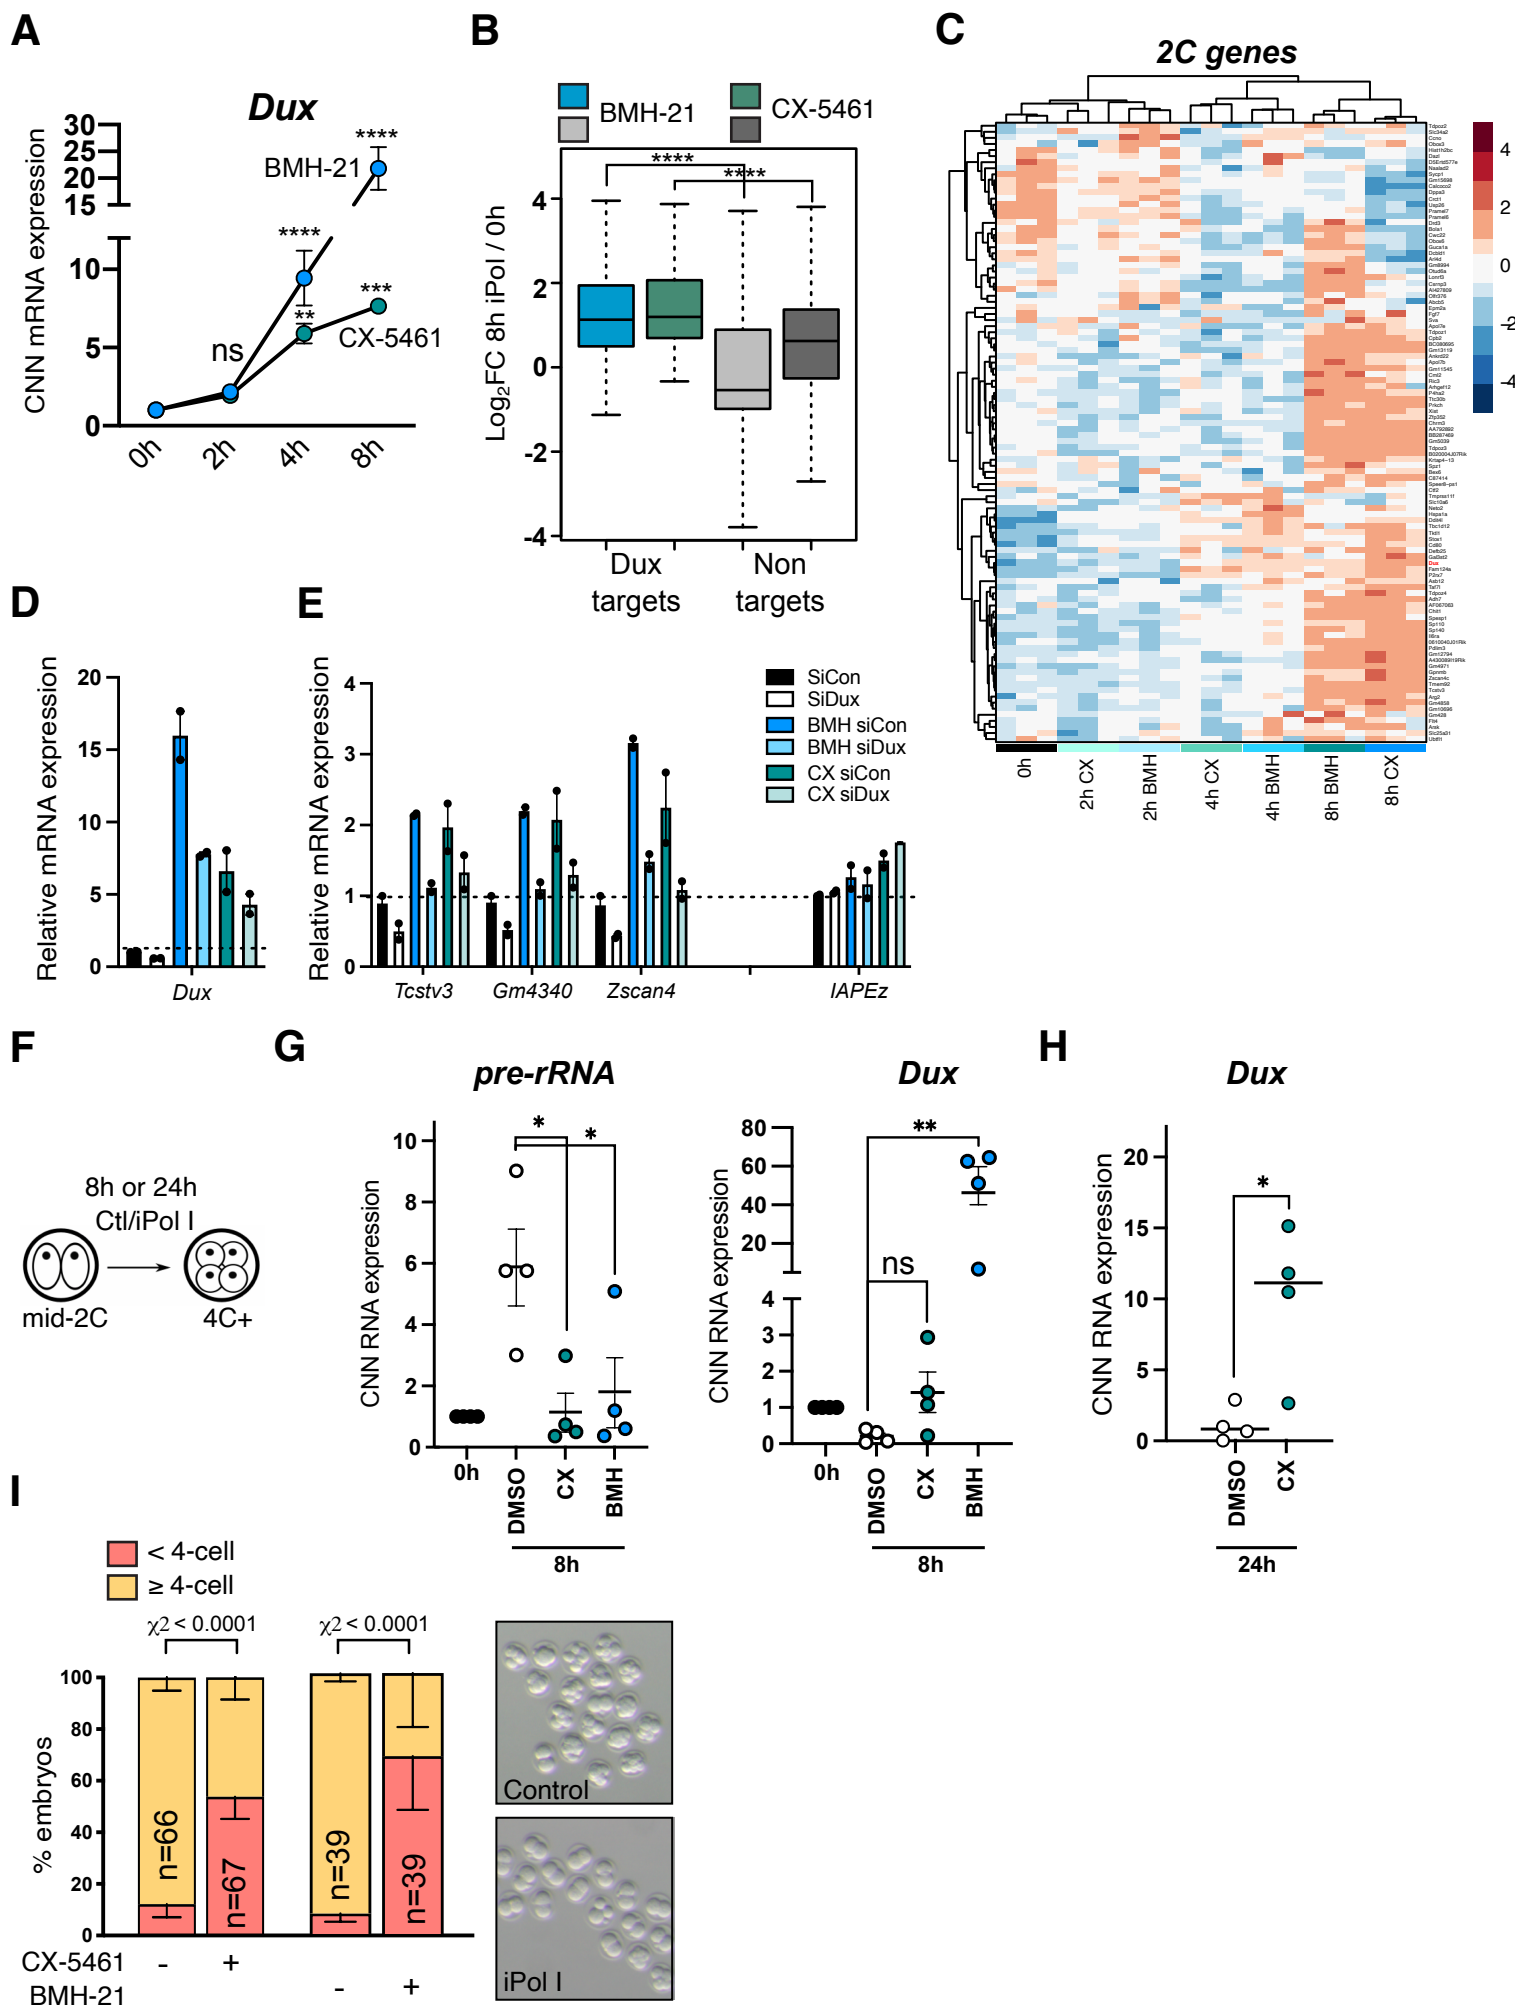

Figure 4

Figure 4. Nucleolar disruption causes *Dux* reactivation in ESCs and embryos.

(A) Cell-number normalised (CNN) qRT-PCR time course analysis of *Dux* upregulation following iPol I. Data are analysed as CNN to exclude potential global effects of iPol I on transcription; however the same results are seen with *Rpl7/H2A* normalisation. Data are mean +/- s.e.m, n=3 biological replicates. P values, two-way ANOVA and Šídák multiple comparisons test.

(B) Boxplot of log2-fold change values for n=99 *Dux* target genes[30] versus significantly altered non-targets (FDR <0.05, n=8057: CX-5461, n=13830: BMH-21) following 8h iPol I. P values, two-sided Wilcoxon rank-sum test.

(C) Heatmap of 2C-specific genes[5] showing gradual upregulation following iPol I. Samples are grouped by unsupervised hierarchical clustering.

(D-E) Expression of (D) *Dux* and (E) 2C-specific genes or a negative control (IAPEz) in iPol I rescue experiments with control or *Dux* siRNAs. Data are mean +/- s.e.m of two independent cell lines, representative of 2 experiments.

(F) Schematic for embryo iPol I inhibitor experiments with 1 μM BMH-21 or CX-5461.

(G) CNN qRT-PCR expression data following 8h iPol I in mid 2-cell embryos showing inhibited *Dux* repression. Data are mean +/- s.e.m, n=4 experiments with equal numbers of embryos, with levels at 0 h set to 1 in each experiment. P values, 1-way ANOVA with Dunnett multiple comparisons correction.

(H) CNN qRT-PCR expression data showing *Dux* upregulation after 24h 1 μM CX-5461. Data are mean +/- s.e.m n=4 experiments. P values, Welch's two-tailed t-test.

(I) Embryo progression rates following 24h iPol I treatment in n=4 experiments (CX-5461) and n=2 experiments (BMH-21). P values, Chi-squared test, n=number of embryos.
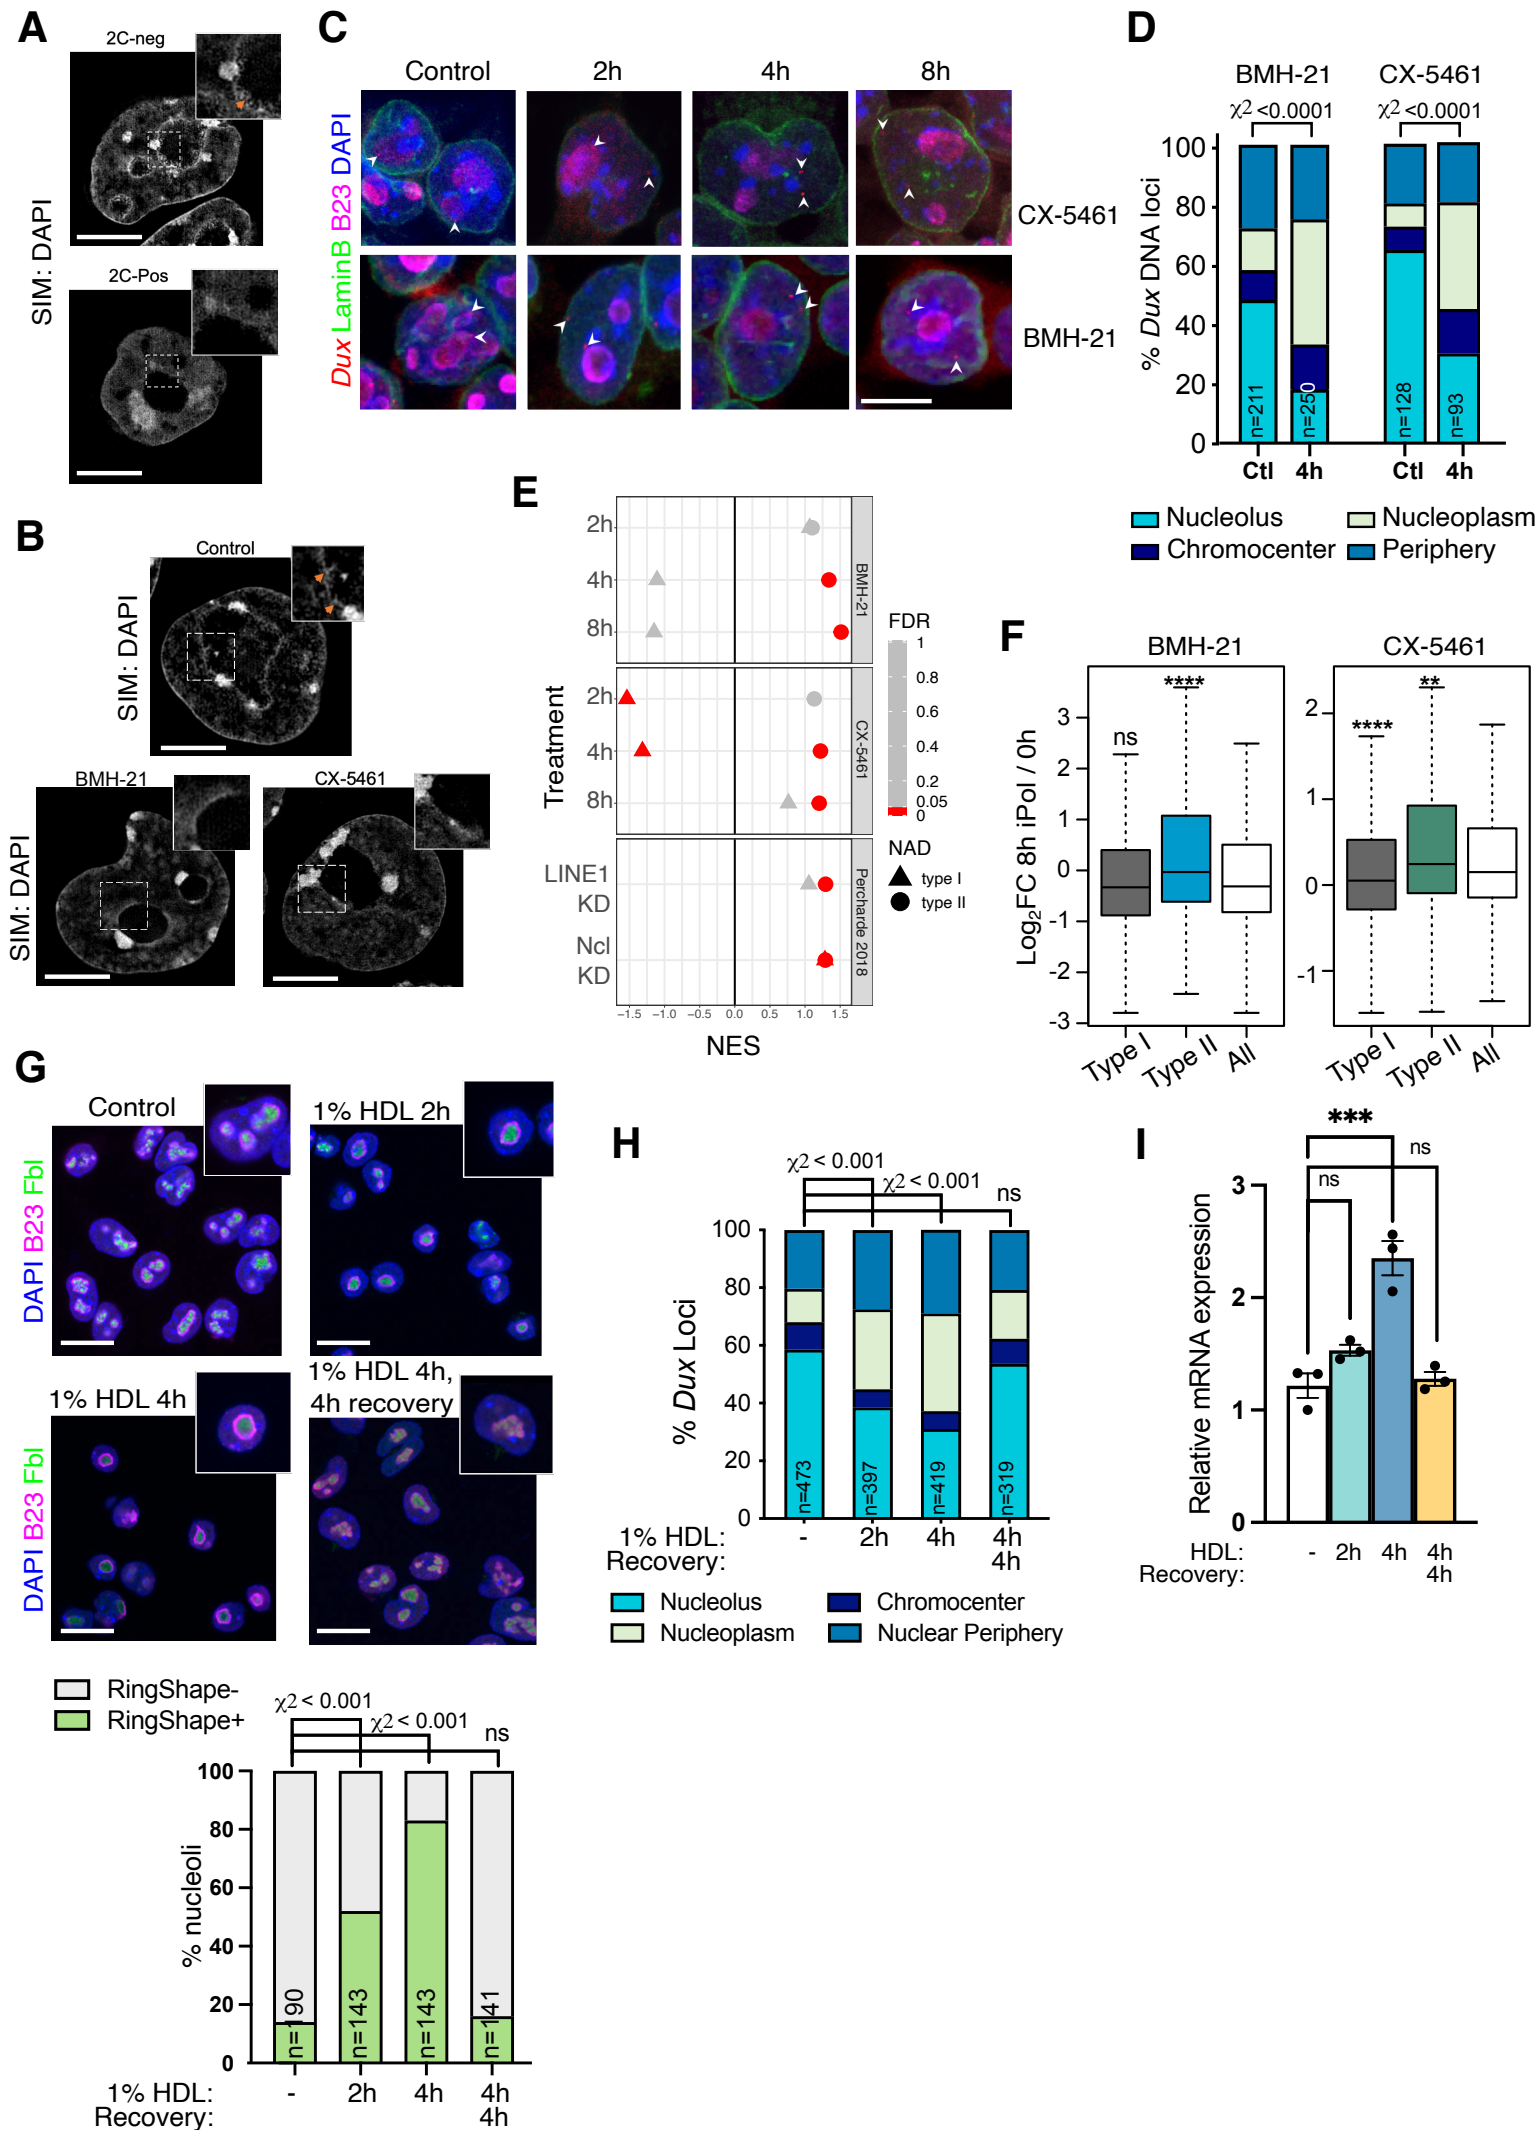

Figure 5 **Xie et al**

Figure 5. Nucleolar disruption induces *Dux* relocalisation and activation

(A-B) Example images of chromatin distribution as marked by DAPI staining in 3D-SIM imaging
   experiments in (A) 2C-pos versus 2C-neg cells and (B) in ESCs upon 8h iPol I. 2C-neg cells
   and (B) control but not iPol I ESCs have nucleolar chromatin fibres, visible as a
