19 Abstract

20 The explosive spread of the Omicron SARS-CoV-2 variant underscores the importance
21 of analyzing the cross-protection from previous non-Omicron infection. We developed a high-
22 throughput neutralization assay for Omicron SARS-CoV-2 by engineering the Omicron spike
23 gene into an mNeonGreen USA-WA1/2020 SARS-CoV-2 (isolated in January 2020). Using this
24 assay, we determined the neutralization titers of patient sera collected at 1- or 6-months after
25 infection with non-Omicron SARS-CoV-2. From 1- to 6-month post-infection, the neutralization
26 titers against USA-WA1/2020 decreased from 601 to 142 (a 4.2-fold reduction), while the
27 neutralization titers against Omicron-spike SARS-CoV-2 remained low at 38 and 32, respectively.
28 Thus, at 1- and 6-months after non-Omicron SARS-CoV-2 infection, the neutralization titers
29 against Omicron were 15.8- and 4.4-fold lower than those against USA-WA1/2020, respectively.

30 The low cross-neutralization against Omicron from previous non-Omicron infection supports
31 vaccination of formerly infected individuals to mitigate the health impact of the ongoing Omicron
32 surge.

33

34 **Main**

35 Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) continues to evolve,
36 leading to the emergence of variants of concern (VoC), variants of interest, and variants of
37 monitoring. These variants can increase viral transmission, immune evasion, and/or disease
38 severity.¹⁻³ The recently emerged Omicron variant (B.1.1.529) was first identified in South Africa
39 on November 2, 2021, and was designated as a new VoC on November 26, along with the four
40 previous VoCs: Alpha, Beta, Gamma, and Delta.⁴ Since its emergence, Omicron has rapidly
41 spread to over 89 countries, with case doubling in as little as 1.5 to 3 days, leading to global
42 surges of COVID-19 cases.⁵ Compared to prior variants, the Omicron spike glycoprotein has
43 accumulated more spike mutations, with over 34 mutations, many of which are known to evade
44 antibody neutralization (e.g., K417N, N440K, S477N, E484A and Q493R) or to enhance
45 spike/hACE2 receptor binding (e.g., Q498R, N501Y, and D614G).^{1,3,6,7} The high number of
46 spike mutations is associated with decreased potency of antibody therapy and increased
47 breakthrough Omicron infections in vaccinated and previously infected individuals⁵. Laboratory
48 studies are urgently needed to examine the susceptibility of Omicron SARS-CoV-2 to vaccine-
49 and infection-elicited neutralization. This study aimed to examine the cross-neutralization of
50 Omicron by antibodies derived from previous non-Omicron infection.

51 To measure neutralization of the Omicron variant, we developed a high-throughput
52 assay. Using a previously established mNeonGreen (mNG) reporter USA-WA1/2020 SARS-
53 CoV-2,⁸ we swapped the original spike gene with an Omicron spike (BA.1 lineage; GISAID

54 EPI_ISL_6640916), resulting in recombinant mNG Omicron-spike SARS-CoV-2 (**Extended Data**
55 **Fig. 1**). The mNG gene was placed at the open-reading-frame-7 (ORF7) of the viral genome.⁹
56 The engineered Omicron spike contained mutations A67V, H69-V70 deletion (Δ 69-70), T95I,
57 G142D, V143-Y145 deletion (Δ 143-145), N211 deletion (Δ 211), L212I, L214 insertion EPE
58 (Ins214EPE), G339D, S371L, S373P, S375F, K417N, N440K, G446S, S477N, T478K, E484A,
59 Q493R, G496S, Q498R, N501Y, Y505H, T547K, D614G, H655Y, N679K, P681H, N764K,
60 D796Y, N856K, Q954H, N969K, and L981F (**Extended Data Fig. 1**). The mNG Omicron-spike
61 virus was sequenced to ensure no undesired mutations. After infecting Vero E6 cells, parental
62 mNG USA-WA1/2020 developed larger fluorescent foci than Omicron-spike SARS-CoV-2
63 (**Extended Data Fig. 2**); however, comparable infectious titers of $>10^6$ focus-forming units per
64 milliliter (FFU/ml) were obtained for both viruses. The mNG viruses were used to develop a
65 fluorescent focus reduction neutralization test (FFRNT) as depicted in **Extended Data Fig. 3**.

66 We examined the cross-neutralization of non-Omicron SARS-CoV-2-infected patient
67 sera against Omicron virus. Two panels of COVID-19 patient sera, one collected at 1-month
68 post-infection (n=64) and another collected at 6-month post-infection (N=36), were measured for
69 their 50% fluorescent focus reduction neutralization titers (FFRNT₅₀, defined as the maximal
70 dilution that neutralized 50% of foci) against both USA-WA1/2020 and Omicron-spike SARS-
71 CoV-2. **Extended Data Tables 1** and **2** summarize the patient information (e.g., age, gender,
72 race, date of positive viral test, symptom, and hospitalization) for the 1- and 6-month post-
73 infection serum panels. All patients were infected before February 2021, prior to the emergence
74 of the Omicron variant. The 1-month post-infection sera neutralized USA-WA1/2020 and
75 Omicron-spike SARS-CoV-2 with geometric mean titers (GMTs) of 601 and 38, respectively
76 (**Fig. 1a** and **Extended Data Fig. 4a**). Only one serum had a neutralization titer of <20 against
77 USA-WA1/2020, whereas 23 of 64 sera had neutralization titers of <20 against Omicron-spike
78 SARS-CoV-2 (**Fig. 1a**). Sera with high neutralization titers against USA-WA1/2020 were from

79 symptomatic patients, most were hospitalized (**Extended Data Table 1**), confirming that
80 neutralizing antibody levels are associated with COVID-19 disease severity.¹⁰ Notably, many of
81 the sera with the highest neutralization titers of >3,450 against USA-WA1/2020 were from
82 patients who had received convalescent plasma treatment (**Extended Data Table 1**).

83 The 6-month post-infection sera neutralized USA-WA1/2020 and Omicron-spike SARS-
84 CoV-2 with GMTs of 142 and 32, respectively (**Fig. 1b and Extended Data Fig. 4b**). Consistent
85 with the 1-month post-infection results, symptomatic hospitalized patients tended to have higher
86 neutralization titers against USA-WA1/2020 than asymptomatic individuals (**Extended Data**
87 **Table 2**). Thus, from 1- to 6-months post-infection, the mean neutralization titers against USA-
88 WA1/2020 waned from 601 to 142 (a 4.2-fold decrease), while the neutralization titers against
89 Omicron-spike virus remained low and nearly unchanged at 38 and 32, respectively. Consistent
90 with our results, the waning neutralization overtime against non-Omicron SARS-CoV-2 was
91 previously reported in naturally infected or vaccinated individuals.¹¹⁻¹³ Our data showed that 1-
92 and 6-months after non-Omicron SARS-CoV-2 infections, the neutralization titers against
93 Omicron were 15.8- and 4.4-fold lower than those against USA-WA1/2020, respectively. A similar
94 range of neutralization reduction against the Omicron virus was reported for two-dose mRNA-
95 vaccinated sera.¹⁴⁻¹⁶ Collectively, these results demonstrate low cross-neutralization against the
96 Omicron variant from previous non-Omicron viral infection or two-dose mRNA vaccination. The low
97 cross-neutralization against the Omicron variant strongly suggests that individuals previously
98 infected with SARS-CoV-2 should be vaccinated to mitigate Omicron-mediated infection,
99 disease, and potential death.

100 Among all tested sera, only 6 pairs of 1- and 6-month samples were collected from same
101 individuals (**Extended Data Tables 1 and 2**). Their neutralization patterns (**Extended Data Fig.**
102 **5**) were similar to those observed with the means from complete 1- and 6-month serum panels.

103 Our study has several limitations. First, we have not defined the contributions of
104 individual spike mutations to Omicron neutralization evasion. The constellation of Omicron spike
105 mutations may result from selection for either viral transmission, immune escape, or both. The
106 emergence of the Omicron variant in South Africa, where herd immunity is believed to be high,
107 is consistent with evolutionary pressure for immune escape as suggested by our data and
108 others.¹⁷ Second, the genotypes of viruses that infected the patients whose sera were analyzed
109 in this study were not defined, although the timing suggests the Alpha variant. Third, we have
110 not analyzed other immune modulators. CD8⁺ T cells and non-neutralizing antibodies that can
111 mediate antibody-dependent cytotoxicity are known to protect patients from severe disease. The
112 Omicron spike mutations may not dramatically affect T cell epitopes.¹⁸

113 The rapid evolution of SARS-CoV-2 underscores the importance of surveillance for new
114 variants and their impact on viral transmission, disease severity, and immune evasion.
115 Surveillance, laboratory investigation, and real-world vaccine effectiveness are essential to
116 guide if and when an Omicron-specific vaccine or booster is needed. Currently, vaccination with
117 booster shots,^{19,20} together with masking and social distance, remain to be the most effective
118 means to mitigate the health impact of Omicron surge. Finally, the high-throughput fluorescent
119 neutralization assay reported in this study can expedite therapeutic antibody screening,
120 neutralization testing, and modified vaccine development.

121

122 **Methods**

123 **Construction of recombinant viruses.** The recombinant mNeoGreen (mNG) Omicron-
124 spike SARS-CoV-2 was constructed on the genetic background of an infectious cDNA clone
125 derived from clinical strain WA1 (2019-nCoV/USA_WA1/2020) containing an *mNG* reporter
126 gene.⁹ The Omicron spike mutations, including A67V, Δ69-70, T95I, G142D, Δ143-145, Δ211,

127 L212I, Ins214EPE, G339D, S371L, S373P, S375F, K417N, N440K, G446S, S477N, T478K,
128 E484A, Q493R, G496S, Q498R, N501Y, Y505H, T547K, D614G, H655Y, N679K, P681H,
129 N764K, D796Y, N856K, Q954H, N969K, and L981F, were engineered using a PCR-based
130 mutagenesis protocol as reported previously.¹ The full-length genomic cDNAs were *in vitro*
131 ligated and used as templates to transcribe full-length viral RNA. Mutant viruses were recovered
132 on day 3 after Vero E6 cells were electroporated with the *in vitro* RNA transcripts. The
133 harvested virus stocks were quantified for their infectious titers (fluorescent focus units) by
134 titrating the viruses on Vero E6 cells in a 96-well plate after 16 h of infection. The genome
135 sequences of the virus stocks were confirmed to have no undesired mutations by Sanger
136 sequencing. The detailed protocol of genome sequencing was recently reported.²¹

137 **Serum specimens.** The research protocol regarding the use of human serum
138 specimens was reviewed and approved by the University of Texas Medical Branch (UTMB)
139 Institutional Review Board (IRB#: 20-0070). The de-identified convalescent sera from COVID-19
140 patients (confirmed by the molecular tests with FDA's Emergency Use Authorization) were heat-
141 inactivated at 56°C for 30 min before testing.

142 **Fluorescent focus reduction neutralization test.** Neutralization titers of human sera
143 were measured by a fluorescent focus reduction neutralization test (FFRNT) using the mNG
144 reporter SARS-CoV-2. Briefly, Vero E6 cells (2.5×10^4) were seeded in each well of black
145 μ CLEAR flat-bottom 96-well plate (Greiner Bio-one™). The cells were incubated overnight at
146 37°C with 5% CO₂. On the following day, each serum was 2-fold serially diluted in the culture
147 medium with the first dilution of 1:20. The diluted serum was incubated with 100-150 fluorescent
148 focus units (FFU) of mNG SARS-CoV-2 at 37°C for 1 h (final dilution range of 1:20 to 1:20,480),
149 after which the serum-virus mixtures were inoculated onto the pre-seeded Vero E6 cell
150 monolayer in 96-well plates. After 1 h infection, the inoculum was removed and 100 μ l of overlay
151 medium (DMEM supplemented with 0.8% methylcellulose, 2% FBS, and 1% P/S) was added to

152 each well. After incubating the plates at 37°C for 16 h, raw images of mNG fluorescent foci were
153 acquired using Cytation™ 7 (BioTek) armed with 2.5x objective and processed using the default
154 software setting. The foci in each well were counted and normalized to the non-serum-treated
155 controls to calculate the relative infectivities. The curves of the relative infectivity versus the
156 serum dilutions (\log_{10} values) were plotted using Prism 9 (GraphPad). A nonlinear regression
157 method was used to determine the dilution fold that neutralized 50% of mNG SARS-CoV-2
158 (defined as FFRNT₅₀). Each serum was tested in duplicates.

159

160 **Statistics**

161 The nonparametric Wilcoxon matched-pairs signed rank test was used to analyze the
162 statistical significance in **Figure 1**.

163 **Data availability**

258 COVID-19 vaccine development. Other authors declare no competing interests.

259

260 **Figure 1.** Reduced neutralization of Omicron SARS-CoV-2 by previous non-Omicron viral
261 infection. 50% fluorescent focus reduction neutralization titers (FFRNT₅₀) were measured for
262 two serum panels from patients previously infected with non-Omicron SARS-CoV-2. The first
263 serum panel was collected at 1-month post-infection (n=64) and the second panel collected at
264 6-months post-infection (n=36). For each serum, FFRNT₅₀ values were determined against
265 mNG USA-WA1/2020 and Omicron-spike SARS-CoV-2. **Extended Data Tables 1** and **2** summarize
266 the FFRNT₅₀ values and serum information for (a) and (b), respectively. Each symbol of dots (a)
267 and triangles (b) represents one serum specimen. The FFRNT₅₀ value for each serum was
268 determined in duplicate assays and is presented as the geometric mean. The bar heights and
269 the numbers above each set of data indicate geometric mean titers. The whiskers indicate 95%
270 confidence intervals. The dotted line indicates the first serum dilution (1:20) of the FFRNT assay.
271 The FFRNT₅₀ values of sera that did not show any inhibition of viral infection are presented as
272 10 for plot purposes and statistical analysis. Statistical analysis was performed using the
273 Wilcoxon matched-pairs signed-rank test. The statistical significance of the difference between
274 the geometric mean titers against USA-WA1/2020 and Omicron-spike SARS-CoV-2 is p
275 <0.0001 in both (a) and (b).
276

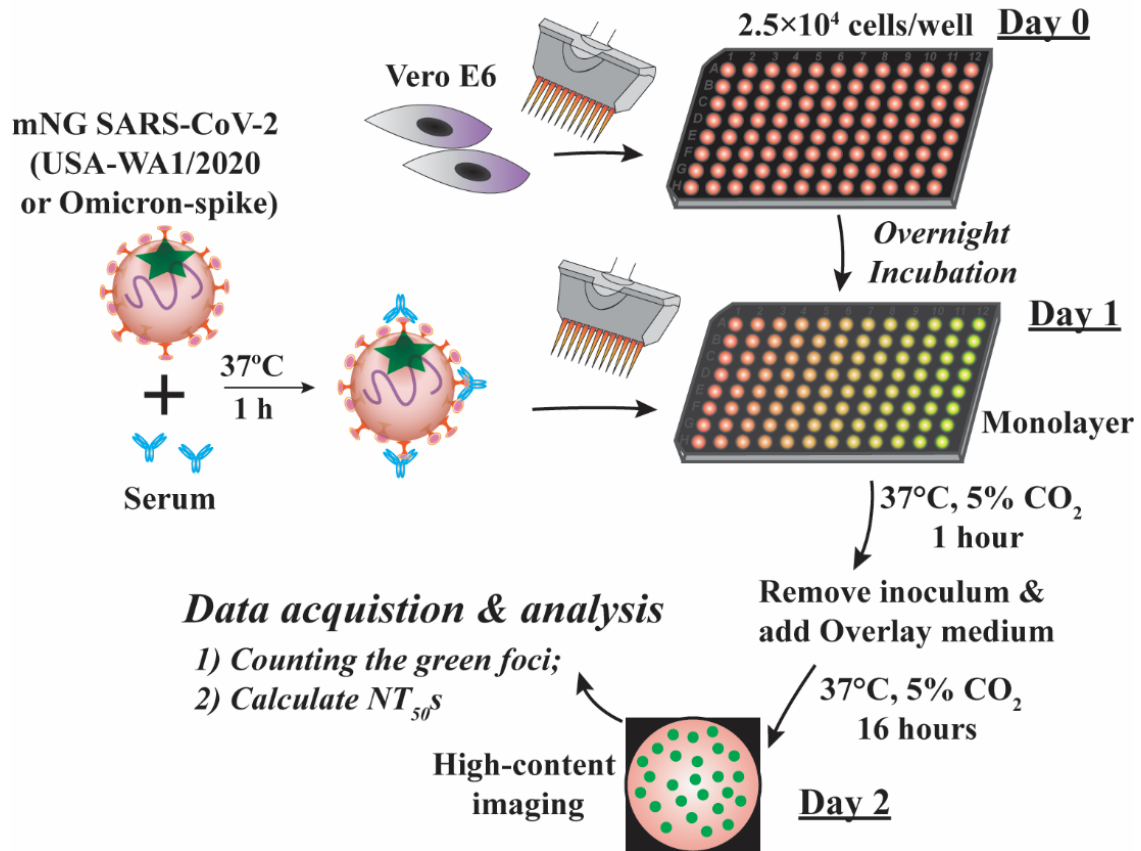

277

278 **Extended Data Figure 1.** Construction of mNeonGreen (mNG) Omicron-spike SARS-CoV-2.
 279 mNG USA-WA1/2020 was used to engineer the complete *spike* gene from the Omicron variant,
 280 resulting in mNG Omicron-spike SARS-CoV-2. Mutations (red circle), deletions (x), and
 281 insertions (+) are indicated. Nucleotide and amino acid positions are depicted. L: leader
 282 sequence; ORF: open reading frame; RBD: receptor binding domain; S: spike glycoprotein; S1:
 283 N-terminal furin cleavage fragment of S; S2: C-terminal furin cleavage fragment of S; E:
 284 envelope protein; M: membrane protein; N: nucleoprotein; UTR: untranslated region.

285

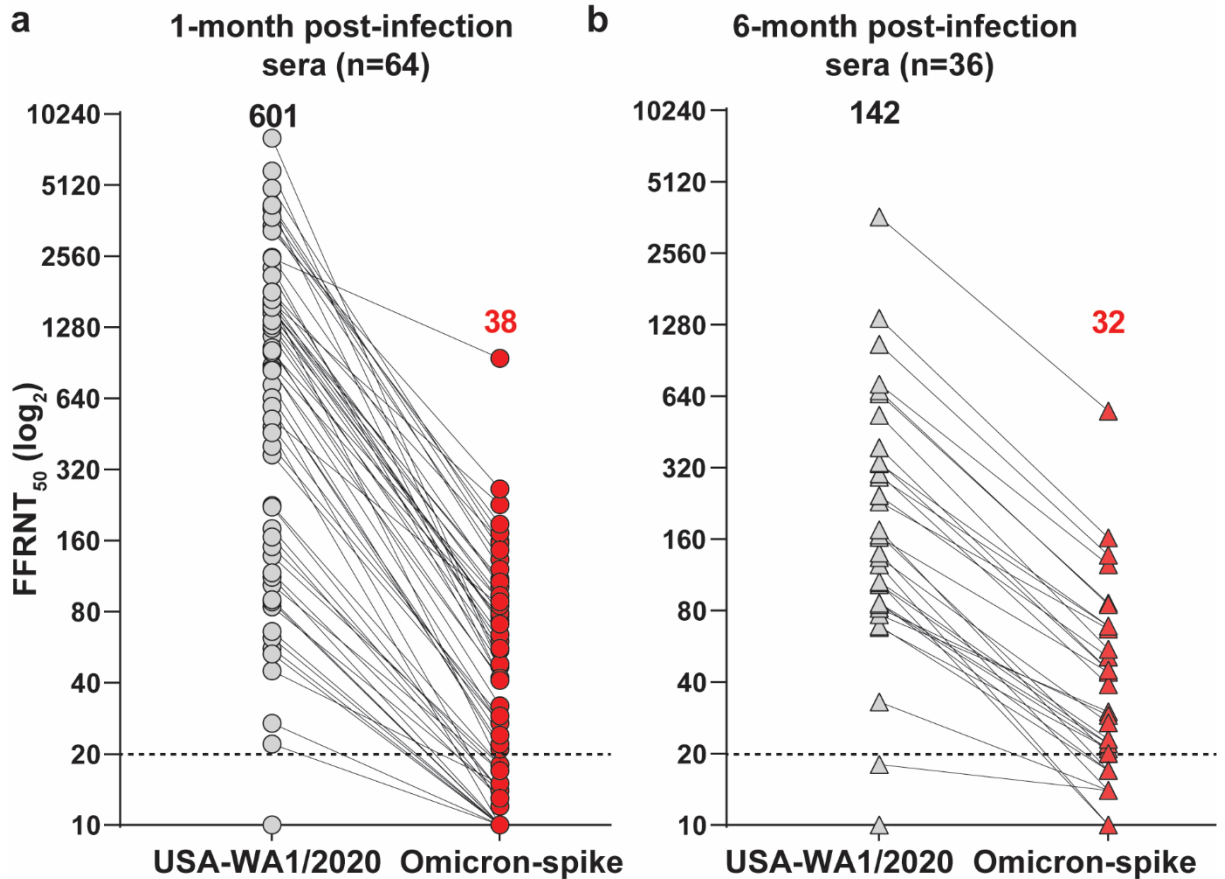

286 **Extended Data Figure 2.** Fluorescent foci of mNG USA-WA1/2020 and mNG Omicron-spike
287 SARS-CoV-2 on Vero E6 cells. Original and processed images were collected by high-content
288 imaging. The protocol of the fluorescent focus reduction neutralization test (FFRNT) is
289 described in Methods. See **Extended Data Figure 3** for the experimental scheme of FFRNT.

290

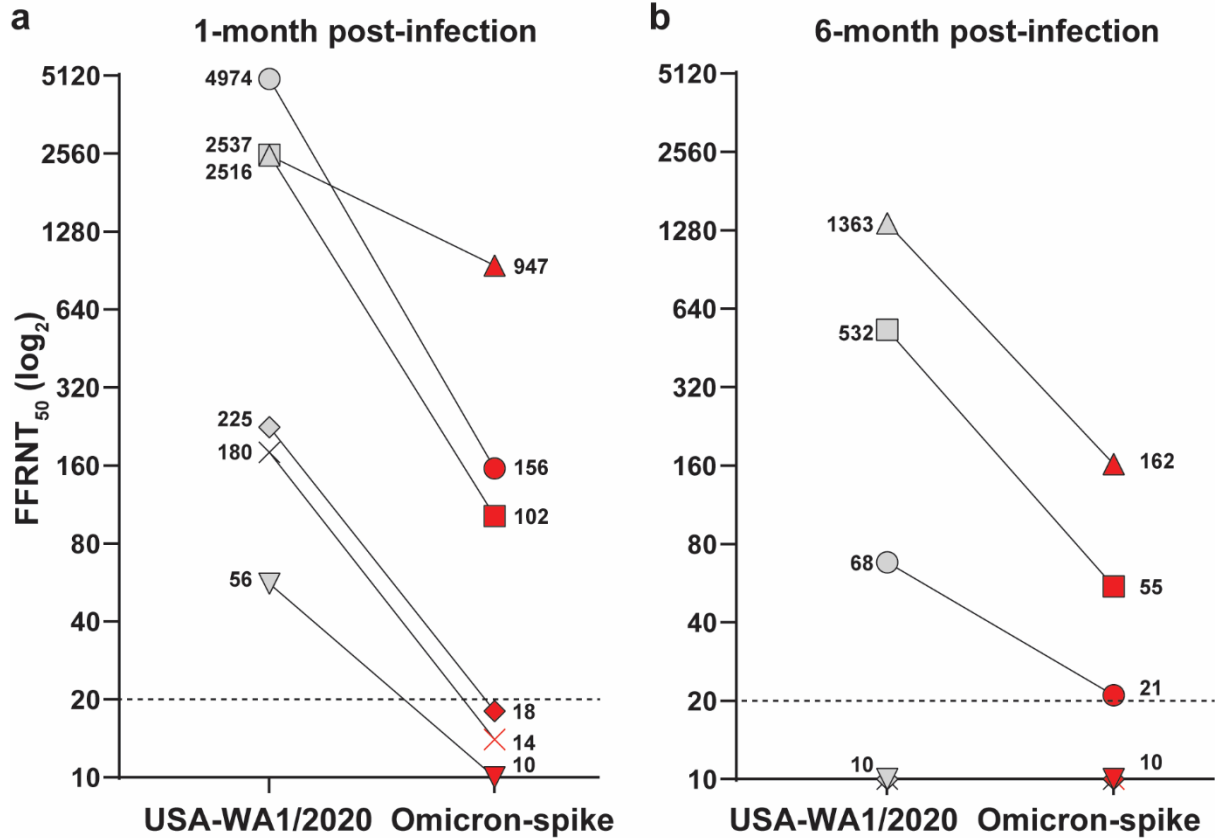

291

292 **Extended Data Figure 3.** Experimental scheme of fluorescent focus reduction neutralization
293 test (FFRNT). The FFRNT protocol is described in Methods.

294

295 **Extended Data Figure 4.** Reduced neutralization against Omicron SARS-CoV-2 by previous
296 non-Omicron viral infection. 50% fluorescent focus reduction neutralization titers (FFRNT₅₀)
297 were measured for two serum panels from COVID-19 patients previously infected with non-
298 Omicron SARS-CoV-2. The first serum panel was collected at 1-month post-infection (n=64)
299 and the second panel collected at 6-month post-infection (n=36). For each serum, two FFRNT₅₀
300 values against mNG USA-WA1/2020 and Omicron-spike SARS-CoV-2 are connected by a line.
301 **a**, FFRNT₅₀s of 1-month post-infection sera. **b**, FFRNT₅₀s of 6-month post-infection sera.
302 **Extended Data Tables 1** and **2** summarize the FFRNT₅₀ values and serum information for (a)
303 and (b), respectively. This figure is a reformat of **Figure 1**.

304

305

306 **Extended Data Figure 5.** FFRNT₅₀ of 6 pairs of 1- and 6-month post-infection sera from same
307 patients. **a**, FFRNT₅₀s of 1-month post-infection sera against mNG USA-WA1/2020 and
308 Omicron-spike SARS-CoV-2. **b**, FFRNT₅₀s of 6-month post-infection sera against mNG USA-
309 WA1/2020 and Omicron-spike SARS-CoV-2.

310 **Extended Data Table 1.** FFRNT₅₀ values of 1-month post-infection sera against mNG USA-WA1/2020 and Omicron-spike SARS-CoV-2
