Abstract

The menthol sensor TRPM8 can be activated by cold and thus serves as a thermometer in a primary afferent sensory neuron for noxious cold detection. However, the underlying design principle is unknown. Here, a hairpin topological structural model and graph theory were prepared to test a role of the cold-dependent hairpin formation in the cold-evoked gating pathway of TRPM8. The results showed that the formation of a large lipid-dependent hairpin initiates a low temperature threshold in favor of TRPM8 activation. Furthermore, two smaller hairpins, which enhance the coupled interactions of the voltage-sensor-like domain with both the pore domain and the TRP domain, can stabilize the cold efficacy and work as a fuse to prevent cold denaturation. The cold-induced hairpin rearrangements along the gating pathway may be necessary for the high cold sensitivity. This hairpin model may provide a structural basis for activation of the thermo-gated TRP channels at low temperature. (150 words)

1. INTRODUCTION

Transient receptor potential (TRP) melastatin-8 (TRPM8) is a Ca^{2+}-permeable nonselective cation channel, serving as a polymodal sensor in response to both physical and chemical stimuli. The physical stimuli include voltage and cold while the chemical stimuli cover phosphatidylinositol-4, 5-biphosphate (PIP$_2$) and cooling agents such as menthol and its analogs WS-12 and icilin. [1-9] As a noxious cold sensor in a mammalian peripheral afferent neuron of the dorsal root and the trigeminal ganglia, TRPM8 has a high temperature sensitivity (Q10 of 40 at pH 6.7) but an activation threshold 22-27°C below a normal human body temperature 37°C. [10-15] Since the TRPM8 channel can be activated by both cold and menthol stimuli in a reversible manner, non-covalent interactions along the gating pathway in TRPM8 may be determinant. However, much less is known about whether both cooling stimuli share the same pathway to gate TRPM8, and what governs those non-covalent interactions during TRPM8 gating. When heat can decrease the menthol-evoked activity of TRPM8 or menthol can sensitize to cold and thus increase the temperature threshold and the saturation temperature of rat TRPM8 (rTRPM8) from 22-26 °C and 8.2 °C to 30-32°C and 15.6°C, respectively, the same gating pathway seems to be shared. [1-2, 10, 16] However, some menthol-sensitive residues such as Y745 and Y1005 in mouse TRPM8 (mTRPM8) are insensitive to cold, challenging the same gating pathway for both stimuli. [17]

Ca^{2+}-bound TRPM8 from *Parus major* (pmTRPM8) has produced the highest resolution for the full-length cryo-electron microscopy (cryo-EM) structural model. [18] This homotetrameric TRPM8 channel has the transmembrane channel layer to interact with a large two-layered cytosolic ring formed by a large N-terminal melastatin homology regions (MHR1-MHR4) and a C-terminal coiled-coil. The transmembrane channel region has a voltage-sensor-like domain (VSLD) with S1-S4 and a pore domain with S5-S6 and the intervening pore helix and a much longer pore loop to form a domain-swapped tetramer, with the VSLD from one subunit interacting with the pore domain of the adjacent one. The channel pore includes the negatively charged selectivity filter at the outer leaflet of the membrane as the upper gate and the S6 bundle crossing within the inner leaflet as the lower gate. The canonical S4-S5 linker and the S6-extended TRP domain are also present for critical channel gating with enough resolution. [18] Unlike TRPV1, the pre-S1 domain of TRPM8 includes the cytosolic pre-S1 helix and a helix-turn-helix (HTH) followed by an interfacial helix that connects to S1. [18-19]

TRPM8 has many aromatic and aliphatic residues between the VSLD and the TRP domain to form a large hydrophobic pocket for the binding of the cooling agents such as menthol and WS-12 and icilin. [21-23] It has been reported that menthol-sensitive R842 in this pocket affects cold-dependent activation of human TRPM8 (hTRPM8). [7] On the other hand, capsaicin or vanillyl butyl ether (VBE), a capsaicin analog, can activate human TRPV1 but inhibit cold-evoked hTRPM8 currents and menthol-sensitive Y745 in this pocket is involved. [24] Therefore, both menthol and cold may employ the same hydrophobic pocket but with distinct sensitive residues to illicit the cooling signal. Since the temperature-dependent gating of the TRPM8 channel is similar to a melting curve of a DNA hairpin thermal sensor, and the increased hairpin loop size can lower the melting temperature, [10, 25-26] it is attractive to use non-covalent interactions in the available cryo-electron microscopy (cryo-EM) structures of frozen TRPM8, together with graph theory, to examine if the cold-dependent hairpin formation along the gating pathway facilitates TRPM8 opening, and which residue is sensitive to cold (Figure 1). On the other hand, intracellular acidic pH6 can prevent cold-evoked activation of TRPM8. [10] Therefore, a putative swapping transition metal bridge between the VSLD and the pore domain, which may be disrupted by the acidic pH6, is proposed to stabilize the cold efficacy. The resultant smaller hairpins may protect the TRPM8 channel from cold denaturation. The role of Ca^{2+} and PIP_2 regulatory sites in and beside this menthol pocket in mediating different gating states were also explored and discussed, respectively. [18, 21] The design maps created in this study may provide further insight into the molecular structural basis for thermosensitive TRP channels as a biological thermometer.

2. RESULTS

2.1. The Non-covalent Interactions along the Gating Pathway form the Primary Hairpin Topological Structures in Ca^{2+}-Desensitized TRPM8 at Low Temperature

The cryo-EM structures of Ca^{2+}-desensitized pmTRPM8 in a frozen state are now available with enough resolution to examine how non-covalent interactions along the gating pathway form primary hairpin topological structures to prime cold activation. [18] First, several pairwise residues can provide the salt bridges to form hairpins. In VSLD, salting pairs have R832 on S4 and D793 on S2, R807 on S3 and E759 on S2, and K753 in the S1-S2 loop and E812 in the S3-S4 loop. In the pore domain, salt-bridging pairs cover R875 on S5 and E896 on the pore helix or D910 on the pore loop, E932 on the pore loop and R880 between S5 and the pore helix, D908 and R918, D917 and K927, R940 and E932 or D934 in the pore loop (Figure 2).

Second, $\pi-\pi$ interactions between aromatic side rings along the gating pathway also generate hairpins (Figure 2). In the VSLD and its interfaces with the pre-S1 domain and the TRP domain, there are three groups with edge-face or face-face $\pi-\pi$ interactions between different helix segments. The first includes W673 on pre-S1, F726 and F729 on S1, and F837 on S4; the second has F739 and F743 on S1, Y763 on S2, F800 on S3, F822 and F826 and F829 on S4; the third contains W777 on S2, Y784 and W789 in the S2-S3 linker, and H835 on S4. In contrast, the pore domain has F871 on S5 and Y953 on S6 or Y898 and F902 on the pore helix as face-face or edge-face $\pi-\pi$ interactions (Figure 2).

Third, H-bonds between different segments also form hairpins. These pairwise H-bonding residues are R988 in the TRP domain and Q666 on pre-S1, Y736 on S1 and R832 on S4, D750 and T756 in the S1-S2 loop, N790 on S3 and D787 or T794 on S3, R852 in the S4-S5 linker and N980 in the TRP domain, D856 on S5 and T972 on S6, Q876 on S5 and S892 or E896 on the pore helix, and T920 and E925 in the pore loop (Figure 2).

Finally, the famous Ca^{2+} site in the menthol pocket also links E773 and Q776 on S2, Y784 in the S2-S3 linker, and D793 and N790 on S3 together (Figure 2). Totally, there are four hairpin groups with the smallest loop sizes to govern non-covalent interactions along the gating pathway: the first group with 0 to 9-residue loops in the outer pore; the second group with 10 to 32-residue loops between S5 and S6; the third group with 2 to 32-residue loops from the TRP domain to the pre-S domain and the VSLD and the S4-S5 linker; the fourth group with 0 to 21-residue loops in the VSLD (Figure 2). Those two intra-domain interactions such as the F837-F729 $\pi-\pi$ interaction in VSLD and the R852-N980 and D856-T972 H-bonds in the pore domain may favor the formation of two large hairpins with 32-residues in loops in frozen TRPM8. However, they are unrelated to the relative movement of the S4-S5 linker against the TRP domain for activation of TRPM8 at low temperature.

2.2. The Inter-domain Interactions Are Required for a Large Hairpin to Facilitate Cold Activation of TRPM8 at a Low Temperature Threshold

Intracellular Ca^{2+} is not needed for cold- or menthol-dependent TRPM8 activation. [1, 4] However, Ca^{2+} binding with a high affinity was proposed to disrupt a putative H-bond between R998 in the TRP domain and Q776 on S2 and thus to desensitize the menthol-evoked TRPM8 activity. [18] Therefore, it is necessary to examine if the R998-Q776 H-bond is present in Ca^{2+}-free TRPM8 with a menthol analog WS-12 bound.

In the absence of Ca^{2+} but presence of WS-12, the cryo-EM structure is different in several ways when compared to the Ca^{2+}-desensitized pmTRPM8 (Figure 3). First, the Ca^{2+} bridge between S2 and S3 is disrupted. Instead, the equivalent side chain H-bonds between Y784 and E773/T794 are emerging. Second, the equivalent aromatic $\pi-\pi$ interactions between F800 and Y763 or F822, Y826 and F743, F837 and F729, and F871 and Y953 are also disconnected. In the meantime, the equivalent edge-face $\pi-\pi$ interaction between F729 on S1 and Y995 in the TRP domain is present. Third, while the equivalent D793-R832 salt bridge is replaced with the D793-R832 H-bond, and the equivalent T756-D750 and R832-Y736 and R852-N980 and D856-T972 H-bonds are broken, the equivalent side chain H-bond between R998 in the TRP domain and Q776 on S2 is indeed generated. In the meantime, Q851 on S5 H-bonds with Q987 in the TRP domain. In this way, an equivalent larger hairpin is shaped with a 32-residue loop from R998 to Q776, W777, Y784, W789, H835, Q851, and Q987, in favor of a low temperature threshold to initiate cold activation of TRPM8 (Figure 3).

2.3. The Putative R998-Q776 H-bond between the TRP domain and the VSLD is Needed for Cold Activation of TRPM8

Capsaicin or its analog VBE has been reported to activate hTRPV1 but to inhibit cold-evoked hTRPM8 currents by targeting menthol-sensitive Y745 (Y736 in pmTRPM8) in the WS-12 or menthol or icilin pocket of hTRPM8. [21, 23-24] The *in silicon* molecular docking demonstrates that in the Ca^{2+}-desensitized state, the vanillyl methoxy group of capsaicin or VBE can H-bond with the hydroxyl group of Y736 of pmTRPM8 while their aromatic rings can form an edge-face $\pi-\pi$ interaction with the aromatic ring of Y736. In the meantime, the amide oxygen of capsaicin or the ether oxygen of VBE can H-bond with the side chains of E773 on S2 or R998 in the TRP domain. In this manner, the lipidic tail of capsaicin or VBE can point toward the crevice between R998 and Q776 to stop the formation of the putative R998-Q776 H-bond (Figure 4A). Therefore, the putative stimulatory R998-Q776 H-bond may be indispensable regarding cold sensing of TRPM8. In agreement with this notion, R998 cannot H-bond with Q776 in the Ca^{2+}-desensitized state (Figure 4A).

2.4. PIP₂ is Necessary to Bridge the TRP Domain with the Pre-S1 Domain for Cold-Evoked Activation of TRPM8

PIP₂ is required for TRPM8 activation because depletion of PIP₂ by poly-lysine can desensitize the channel. [5-7, 9, 27] In contrast, PIP₂ alone can activate vertebrate TRPM8, possibly

by interacting with K995 (K985 in pmTRPM8), R998 (R988 in pmTRPM8), and R1008 (R998 in pmTRPM8) in the TRP domain. [5] Although the stimulatory R998-Q776 H-bond is important for cold activation of TRPM8, it is only shown in the presence of WS-12 and PIP$_2$ but not observed in the presence of cholesterol hemisuccinate (CHS) only or in the absence of PIP$_2$ (Figure 4A). Therefore, PIP$_2$ is required for cold-evoked activation of TRPM8. The *in silicon* research demonstrates that PIP$_2$ can bind to the interface between pre-S1 and TRP domains, promoting the gating coupling of the menthol pocket with the pore domain in pmTRPM8 in several ways (Figure 4B). First, the electrostatic interactions of the C4 phosphate moiety of PIP$_2$ with the side chains of both R679 on pre-S1 and K988 in the TRP domain can stabilize edge-face $\pi-\pi$ interactions among aromatic rings of W673 on pre-S1 and F726/F729 on S1 and Y995 in the TRP domain. Second, those interfacial electrostatic interactions between PIP$_2$ and pmTRPM8 rearrange S4 to disrupt the inhibitory R832-D793 salt bridge for a release of the "parking brake". [23] Third, those interfacial electrostatic interactions rotate the TRP helix in favor of the formation of the stimulatory R998-Q776 H-bond (Figure 4B). [21]

2.5. The Putative Swapping Transition Metal Bridge between the VSLD and the Pore Domain is Required to Stablize the Cold Efficacy of TRPM8

Although several cryo-EM structures of TRPM8 in the sensitized state are available, none is conducting cations through the channel pore. [18-19, 21] Since intracellular PH6 can suppress cold-evoked TRPM8 activation, H835 on the voltage sensor S4, which is sensitive to acidic pH and included the cold-dependent large hairpin formation with a 32-residue loop, may be involved. However, protonation of H835 cannot disconnect the H835-W789 interaction. Even if their $\pi-\pi$ interaction is weakened by protonation, a cation-π interaction is still present between two aromatic residues. The *in silicon* investigation reveals that in the Ca^{2+}-desensitized TRPM8, F858 on S5 is far away from W789 on S3. On the other hand, in the presence of low Ca^{2+} occupancy, even if Ca^{2+} can bind to E773 on S2 and T794 and N790 on S3 but leave Q776 free to form the stimulatory H-bond with R998, F858 is close to W789 but not enough to form a well-established face-face ot edge-face $\pi-\pi$ interaction in the sensitized state (Figure 5A). The similar case was also found in the Ca^{2+}-free closed state (Figure 5A). When WS-12 and PIP$_2$ are bound to TRPM8, even if the stimulatory R998-Q776 H-bond and the related large hairpin are available as a cold starter to allow a low temperature threshold to initiate TRPM8 activation, F858 is still not close enough to W789 to form a typical edge-face attractive $\pi-\pi$ interaction to stablize the cold efficacy (Figure 3).

Therefore, protonation of H835 may disrupt the cold-evoked gating pathway of TRPM8 in another manner.

The cryo-EM structure of TRPM8 with WS-12 and PIP_2 bound indicates that M854 is close to F858 on S5 and H835 on S4 and W789 on S3 from one subunit, and N958 on S6 from the neighboring subunit (Figure 5A). Sequence alignment of the TRPM family shows that M854 is highly conserved (Figure 5B). It is also intriguing that both thioether ligation with methionine and strong cation-π interactions with tryptophan can stabilize Cu(I) binding in protein CusF. [28] In this regard, it is possible that a strong interaction can be formed between a cationic metal-thioether/imidazole center and the aromatic ring of W789 in the sensitized state. When such a transition metal ion is bound between H835 and W789 via a cation-π interaction, EGTA at a concentration up to 10 mM cannot remove it. [4, 16, 17, 21, 24-25, 29] Further, a dynamic swapping interaction between this metal site from one subunit and N958 on S6 from an adjacent subunit may turn S6 against S5 in favor of opening of both the upper and lower gates (Figure 5). [18] Thus, this dynamic swapping interface between the VSLD and the pore domain may be required for a precise thermodynamic tuning of the cold-evoked TRPM8 activation.

When this putative transition metal site bridges W789 and H835 and M854 together, the smallest hairpin with no residue in the loop is born. What is more, in the desensitized TRPM8 with TC-I 2014 or AMTB bound, R998 in the TRP domain was found to H-bond with not only Q776 but also D772 on S2. In this case, the H-bonded R998 and Q776 and D772 may create another smaller hairpin with a 3-residue loop. However, the putative transition metal bridge between the VSLD and the pore domain is missing in the desensitized state. [18] Taken together, these two small interfacial hairpins may be required to stabilize the cold-evoked efficacy and to stop cold denaturation.

3. DISCUSSION

The TRP channels have a selectvity filter as the upper gate and the S6 bundle crossing as the lower gate to conduct the monvalent or divalent cation permeation throught the ion channel pore. Since these two gates are coupled to each other, opening of either gate can prime channel opening. The cryo-EM structural data show that the heat-sensing TRPV1 has a dynamic pore domain and a relatively static VSLD. [20] In contrast, both the VSLD and the pore domain in the cold-sensing TRPM8 are dynamic. [30, 18-19, 21] Thus, it is exciting to examine if temperature-dependent hairpin melting or formation along the gating pathway triggers activation of the

thermosensitive TRP channels. When the heat-evoked melting of a larger hairpin in the outer pore was proposed to initiate TRPV1 activation, [31] it is necessary to test if the cold-dependent formation of a larger hairpin in TRPM8 is responsible for the start of channel opening.

The lower S6 gate of the TRP channel is determined by the relative movement of the S4-S5 linker against the VSLD or the TRP domain. The uplift of the S4-S5 linker can drive TRPV1 opening. [32] However, little is known about how the lower S6 gate is opened by cold in TRPM8. Although the cryo-EM structures of TRPM8 were obtained in a frozen state, none is conducting Ca^{2+}. [18-19, 21] Therefore, other experimental or *in silicon* approaches are needed to identify cold-sensitive residues and the relevant gating pathway for design maps of TRPM8 as a thermometer.

Because capsaicin or its analog VBE can completely inhibit cold-evoked hTRPM8 currents and menthol-sensitive Y745 in the WS-12 or menthol or icilin pocket is involved, [21, 23-24] this menthol pocket may be intricate in the cold-initiated gating pathway of TRPM8. Since the molecular docking demonstrates that the short tail of VBE can disrupt the putative R998-Q776 H-bond when its vanillyl group H-bonds with the hydroxyl group of Y736 (Y745 in hTRPM8), the R998-Q776 H-bond may play a stimulatory role in the cold-evoked activation of TRPM8. In support of this proposal, Ca^{2+} binding can bridge E773 and Q776 on S2, Y784 in the S2-S3 linker, and D793 and N790 on S3 together to disrupt the putative stimulatory R998-Q776 H-bond for desensitization. [18, 21] As Ca^{2+} binding cannot change the temperature threshold of TRPM8, [25] it is proposed that Ca^{2+} binding to E773 on S2 and T794 and N790 on S3 with low affinity may leave dynamic Q776 on S2 free to form the putative stimulatory H-bond with R998 in the TRP domain (Figure 5A). This affinity-dependent dynamic Ca^{2+} site is reminicant of the active and dynamic Zn^{2+} site at the T_1-T_1 interface of Kv4 channels. [33] In the absence of Ca^{2+}, the equivalent H-bond between E773 on S2 and T794 or N790 on S3 may also favor the cold-evoked R998-Q776 H-bond for pmTRPM8 activation (Figure 5A). Once the R998-Q776 H-bond is formed, the Q851-Q987 H-bond between S5 and the TRP domain, together with the H835-W789 and Y784-W777 $\pi-\pi$ interactions and the Y784-T794 H-bond, produces a large hairpin with a 32-residue loop. This large hairpin loop starts from Q851 on S5 and links H835 on S5, W789 on S3, Y784 and W777 in the S2-S3 linker, Q776 on S2, R998 and Q987 in the TRP domain together for a low temperature threshold to initiate cold activation of TRPM8 (Figure 3).

On the other hand, extracellular acidic and alkaline pH can decrease and increase the temperature thresholds for cold activation of TRPM8, respectively. More importantly,

intracellular pH6 can completely prohibit the cold-evoked activation of TRPM8. [10] Thus, when acidic pH-sensitive H835 in the large cold-dependent hairpin can form a face-face π–π interaction with W789 on S3, both H835 and W789 can also sandwich a transition metal ion with a very high affinity via a cation-π interaction. [29] This putative transition metal cation may be Zn^{2+}, Cu^+, Cu^{2+}, Fe^{2+}, or Fe^{3+}, depending on a different cellular redox environment. Previous studies demonstrated that these transition metal ions can bind to ion channels such as cystic fibrosis transmembrane conductance regulator (CFTR) and *Slo* BK_{Ca} and Kv4 channels, regulating channel gating. [29, 33-39] When the sandwiched transition metal cation interacts with M854 on S5, the additional swaping dynamic interaction between this metal site from one subunit and N958 on S6 from another adjacent subunit may facilitate the relative movement of the pore domain against the VSLD and the TRP domain in favor of opening of both upper and lower gates in the channel pore. Thus, the putative transition metal bridge of M854 on S5 with H835 on S4 and W789 on S3, together with the H-bond between R998 in the TRP domain and D772 or Q776 on S2, can prepare two smaller hairpins with 0 to 3-residue loops to stabilize the cold efficacy and to avoid cold denaturation (Figure 3).

The ligand-free cryo-EM structure of pmTRPM8 indicates that the stimulatory R998-Q776 H-bond is absent to drive TRPM8 opening. [18-19, 21] On the other hand, high concentrations of PIP_2 can increase the temperature threshold from 20-28°C to 32–37°C for TRPM8activation under naive conditions, but depletion of PIP_2 by poly-lysine can completely stop cold-evoked TRPM8 activation. [5] Thus, PIP_2 is required for cold-driven TRPM8 opening. In sharp contrast, the release of the resident phosphatidylinositol lipid in the vanilloid site is necessary for heat or vanilloid compouds to activate TRPV1. [31, 40]

The orientation of the side chain of R998 in pmTRPM8 is important for the putative stimulatory R998-Q776 H-bond. The cryo-EM structures of pmTRPM8 denote that R998 (R1008 in mTRPM8 or hTRPM8) cannot form a stable H-bond with Q776 (Q785 in mTRPM8 or hTRPM8) in the absence of lipid bound between the TRP domain and the pre-S1 domain. When PIP_2 interacts with R988 in the TRP domain and K679 and N683 in the pre-S1 domain, a rotation of the TRP domain may pull Y995 close to F729 on S1 and W673 on pre-S1 to form attractive edge-face π–π interactions as a stable anchor in support of the putative stimulatory R998-Q776 H-bond. That's why high concentration of PIP_2 alone can activate TRPM8 at a warm temperature (Figures 3-4). Regarding the exposed-temperature-dependent changes in temperature thresholds

of hTRPM8 upon the interaction of PIP$_2$ with R1008 (R998 in pmTRPM8), [25] it is possible that the presence of K995 (K985 in pmTRPM8) or R998 (R988 in pmTRPM8) in the TRP helix, and R688 (R679 in pmTRPM8), or K691 (K682 in pmTRPM8) or K694 (K685 in pmTRPM8) in the pre-S1 helix may allow PIP$_2$ to serve as a gear to interact with different positive residues between the TRP domain and the pre-S1 domain to tune the intensity of the putative R1008-Q785/D781 (R998-Q776/D772 in pmTRPM8) H-bonds for different thresholds in response to varied ambient temperatures (Figure 5B).

Since Ca^{2+} binding with a high affinity between S2 and S3 can desensitize the menthol-evoked activation, [18, 23] when the putative H-bonded homochiral menthol dimer pushes the side chain of Y995 (Y1005 in hTRPM8) in the TRP helix away from the lower S6 bundle crossing gate against S4, it may bring R998 (R1008 in hTRPM8) in the same TRP helix close to Q776 (Q785 in hTRPM8) to form the stimulatory H-bond for the cold-started activation of TRPM8. That's why menthol can elevate the temperation threshold of TRPM8 for cold activation at pH 7.4. [1-2, 10, 41] As both menthol and PIP$_2$ can reposition the TRP domain in different ways for the stimulatory equivalent R998-Q776/D772 H-bond, it is reasonable that both cold and menthol can increase the apparent affinity of the TRPM8 channel for PIP$_2$. [5] In this regard, the stimulatory R998-Q776/D772 H-bond may also be indispensable for TRPM8 activation by the H-bonded homochiral menthol dimer. [23]

The TRPM family, part of the TRP channel superfamily, has eight members (TRPM1 to TRPM8). In addition to cold-sensitive TRPM8 (<20–28 °C), cold to warm-sensitive TRPM channels include TRPM2 (>36°C), TRPM4 and TRPM5 (>22 °C) but TRPM3 is a sensor for noxious heat. [1, 42-45] Sequence alignment of the TRPM family indicates that some highly conserved residues may be important for cold to warm sensitive TRPM channels. While the equivalent stimulatory R998-Q776/D772 H-bonds are almost conserved among all the TRPM family, the putative dynamic swapping transition metal site with high affinity may be only highly conserved among human TRPM2, TRPM4, TRPM5 and TRPM8 but not in human TRPM6-7 and TRPM1 and TRPM3 (Figure 5B). Accordingly, both the R998-Q776/D772 H-bonds and the N958-Metal-M854/H835/W789 bridge are indispensable and coupled together as a team for the cold-evoked activation of TRPM8.

4. CLOSING REMARK

The TRPM8 channel can be activated by both cold and cooling agents such as menthol and its analog WS-12. Since the menthol pocket is required for cold-activation, both physical and chemical stimuli may share the same gating pathway although residues sensitive to cold and menthol may be different. While the putative Ca^{2+}-independent H-bond between the Ca^{2+} site in VSLD and the C-terminal of the TRP helix is responsible for the larger hairpin formation to ensure the low temperature threshold, the putative dynamic swapping interfacial transition metal bridge between the VSLD and the pore domain, together with Ca^{2+}-independent H-bonds between VSLD and the TRP helix, is needed to form the smallest hairpins to stabilize the cold efficacy and to prevent cold denaturation. The cold-induced global hairpin rearrangements along the gating pathway from the dynamic interface between the VSLD and the TRP domain to the dynamic interface between the VSLD and the pore domain may prime the high temperature coefficient or Q10. Taken all these into account, this study may further support the hypothesis regarding the temperature-dependent topological hairpins for thermosensitive TRP channels.

5. MATERIALS AND METHODS

In this *in silicon* study, the hairpin topological structural aspects of TRPM8 channels in different states at low temperature were investigated and analyzed with graph theory as the thermometer basis for noxious cold detection. The *in silico* protomer models were based on the cryo-EM structural data of closed pmTRPV1 with CHS-bound (PDB ID, 6O6A) and additional Ca^{2+}-bound (PDB ID, 6O77), [18] sensitized cfTRPM8 with WS-12 and PIP$_2$ bound (PDB ID, 6NR2), desensitized cfTRPM8 with icilin and Ca^{2+} and PIP$_2$ bound (PDB ID, 6NR3), and denatured cfTRPM8 without PIP$_2$ bound (PDB ID, 6BPQ). [19, 21] UCSF Chimera was used for molecular docking and topological hairpin analyses.

For molecular docking, the different rotamers of the residues in the menthol pocket of TRPM8 were tested to optimally interact with the introduced capsaicin or VBE. The different orientations of the test molecules were also examined to make sure that their spatial hindrance in the pocket is minimal but their non-covalent interactions with nearby residues in the pocket are maximal.

For topological hairpin analyses, all the potential non-covalent interactions such as salt and metal bridges and π−π or cation-π interactions and H-bonds along the gating pathway in TRPM8 were included to examine their possible roles in forming the smallest hairpins, controlling the temperature threshold and the temperature sensitivity Q10, and stablizing the cold afficacy. The

smallest hairpin sizes to govern the thermostability of non-covalent interactions were calculated using graph theory. The different residues for activation of TRPM8 by cold and the cooling agents such as menthol were also compared. Q10 was used to characterize the temperature-dependent responses as calculated using the following equation:

$$Q_{10} = (R2/R1)^{10/(T2-T1)}$$

Figure legends

Figure 1 The hairpin test model for examining the cold-evoked gating pathway of TRPM8 channels. Non-covalent interactions such as salt and metal bridges and aromatic side chain $\pi-\pi$ interactions and H-bonds in the TRPM8 channel are proposed to form hairpins with different loop sizes. Low and high temperature thresholds allow hairpins with the large and small loops to form, respectively. The physical and chemical stimuli including ionic strength on the hairpin loop can regulate the loop plasticity for different temperature thresholds. Only the hairpin opening and closure along the gating pathway may govern the temperature threshold and cold efficacy for TRPM8 activation.

Figure 2. The non-covalent interactions (**A**) and the hairpins map (**B**) of Ca^{2+}-desensitized TRPM8 along the gating pathway. **A,** The non-covalent interactions were based the cryo-EM structure of pmTRPM8 with Ca^{2+} bound (PDB ID, 6O77). [18] Salt and metal bridges and H-bonds and $\pi-\pi$ interactions enhance the intra- and inter-domain interactions along the gating pathway. The residues are colored in red for a positive charge or blue for a negative charge in salt bridges or H-bonds, dark blue for metal bridges, orange for the uncharged residues in H-bonds, and green for $\pi-\pi$ interactions. The aromatic pairs for $\pi-\pi$ interactions are mainly clustered in the VSLD and its interfaces with the pre-S1 domain and the TRP domain. **B**, The pore domain, the S4-S5 linker, the TRP domain, the VSLD and the pre-S1 domain are indicated. Salt bridges, the metal bridge, $\pi-\pi$ interactions, and H-bonds are marked in purple, dark blue, green and orange, respectively. The smallest hairpin loop sizes required to control the non-covalent interactions were calculated using graph theory and labeled.

Figure 3. The non-covalent interactions (**A**) and the hairpins map (**B**) of sensitized TRPM8 along the gating pathway in the presence of WS-12 and PIP$_2$. **A,** The non-covalent interactions in pmTRPM8 were based on the cryo-EM structure of sensitized cfTRPM8 in the presence of WS-12 and PIP$_2$ (PDB ID, 6NR2). [21] Salt bridges and H-bonds and $\pi-\pi$ interactions enhance the intra- and inter-domain interactions along the gating pathway. The residues are colored in red for a positive charge or blue for a negative charge in salt bridges or H-bonds, orange for the uncharged residues in H-bonds, and green for $\pi-\pi$ interactions. The aromatic pairs for $\pi-\pi$ interactions are mainly clustered in the VSLD and its interfaces with the pre-S1 domain and the TRP domain. **B**,

The pore domain, the S4-S5 linker, the TRP-like domain, the VSLD and the pre-S1 domain are indicated. Salt bridges, π–π interactions and H-bonds are marked in purple, green and orange, respectively. The dashed lines are putative non-covalent interactions for cold activation of TRPM8. The smallest hairpin loop sizes required to control the non-covalent interactions were calculated using graph theory and labeled. The putative loop sizes are marked in grey.

Figure 4. PIP$_2$ is required for the stimulatory R998-Q776 H-bond in TRPM8. **A,** Non-covalent interactions of TRPM8 in the menthol pocket in different gating states. The *in silicon* protomer models were based on the cryo-EM structural data of pmTRPM8 or cfTRPM8 in the closed (PDB ID: 6O6A), sensitized (PDB ID: 6NR2 or 6NR4), desensitized (PDB ID, 6NR3) and denatured (PDB ID, 6BPQ) states. [18, 21] The reposition of the TRP domain against the VSLD faciliates the lower S6 gate opening. When the temerature is lowered below a threshold, PIP$_2$ can bridge R679 and N683 on pre-S1 and R988 in the TRP domain and K596 from the adjacent subunit, stablizing the aromatic edge-face π–π interactions of Y995 in the TRP domain with both F729 on S1 and W673 on pre-S1 in favor of the stimulatory side chain H-bond between R998 in the TRP domain and Q776 on S2. On the other hand, either Ca^{2+} binding between S2 and S3 or VBE binding with the tail between R998 and Q776 may break the stimulatory R998-Q776 H-bond to desensitize or to inactivate the TRPM8 channel, respectively.

Figure 5 The trace transition metal ion in the swapping dynamic interface between the VSLD and the pore domain of TRPM8 is required for cold-evoked efficacy. **A,** The effects of intracellular Ca^{2+} and transition metal ions on the gating states of TRPM8. The different states were based cryo-EM structures of TRPM8: closed (PDB ID, 6O6A), sensitized (PDB ID, 6NR2 or 6NR4), desensitized (PDB ID, 6NR3) and open (PDB ID, 6NR2). [18, 21] Intra-subunit Ca^{2+} binding to E773 on S2 and N790 and T794 on S3 sensitizes TRPM8 at low occupancy for the stimulatory R998-Q776 H-bond. However, Ca^{2+} binding to E773 and Q776 on S2 and N790 and D793 on S3 and Y784 in the S2-S3 linker at high occupancy desensitizes TRPM8 by disrupting the R998-Q776 H-bond. On the other hand, a putative inter-subunit transition metal site is required to glue swapped S5 and S6 close to open the lower and upper gates simultaneously. The metal binding ligands include W789 on S3 and H835 on S4 and M854 on S5 from one subunit, and N958 on S6 from the neighboring subunit. The Ca^{2+} binding with high affinity seperates M854 away from

W789 and H835 to prevent the stimulatory and dynamic and interfacial swapping metal bridge with N958. **B**, Sequence alignment of TRPM channel family members. Residues discussed in the text are bolded and colored. Numbers above and below the sequences refer to mTRPM8 and hTRPM1 channels, respectively. The residues are colored in red for a positive charge or blue for a negative charge in salt bridges or H-bonds, orange for the uncharged residues in H-bonds, green for $\pi-\pi$ interactions, dark blue for metal bridges. N958 is from the neighboring subunit and marked in different blue. The upper non-covalent interactions favor the open state while the lower ones desensitize TRPM8.
