# 1 **ABSTRACT**

2 Mice with deletion of complex I subunit Ndufs4 develop mitochondrial encephalomyopathy resembling Leigh  
3 syndrome (LS). We report that LS mice also develop severe cardiac bradyarrhythmia and diastolic dysfunction.  
4 Human induced pluripotent stem cell-derived cardiomyocytes (iPS-CMs) with Ndufs4 deletion recapitulate LS  
5 cardiomyopathy. Mechanistically, we demonstrate a direct link between complex I deficiency, decreased  
6 intracellular  $\text{NAD}^+/\text{NADH}$  and bradyarrhythmia, mediated by hyperacetylation of the cardiac sodium channel  
7  $\text{Na}_v1.5$ , particularly at K1479 site. Neuronal apoptosis in the cerebellar and midbrain regions in LS mice was  
8 associated with hyperacetylation of p53 and activation of microglia. Targeted metabolomics revealed increases  
9 in several amino acids and citric acid cycle intermediates, likely due to impairment of  $\text{NAD}^+$ -dependent  
10 dehydrogenases, and a substantial decrease in reduced Glutathione (GSH). Metabolic rescue by nicotinamide  
11 riboside (NR) supplementation increased intracellular  $\text{NAD}^+/\text{NADH}$ , restored metabolic derangement, reversed  
12 protein hyperacetylation through  $\text{NAD}^+$ -dependent Sirtuin deacetylase, and ameliorated cardiomyopathic  
13 phenotypes, concomitant with improvement of  $\text{Na}_v1.5$  current and SERCA2a function measured by  $\text{Ca}^{2+}$ -  
14 transients. NR also attenuated neuronal apoptosis and microglial activation in the LS brain and human iPS-  
15 derived neurons with Ndufs4 deletion. Our study reveals direct mechanistic explanations of the observed  
16 cardiac bradyarrhythmia, diastolic dysfunction and neuronal apoptosis in mouse and human iPSC models of LS.

# 1 INTRODUCTION

2 Leigh syndrome (LS) is a severe mitochondrial disorder that manifests as psychomotor regression early in  
3 life (1), and treatment options are very limited, as is the case for many mitochondrial disorders. The most  
4 common causes are mutations in components of mitochondrial complex I, NADH dehydrogenase, which  
5 consists of 45 subunits, one of which is NADH dehydrogenase [ubiquinone] iron-sulfur protein 4 (Ndufs4).  
6 Mice with a homozygous germline deletion of exon 2 of the encoding gene (*Ndufs4*<sup>-/-</sup>) exhibit phenotypes  
7 resembling the severe encephalomyopathy in LS patients (2). These include features of growth retardation,  
8 lethargy, loss of motor skills, ataxia, hypothermia, slowed breathing and apnea. The latter has been shown to  
9 contribute to early death (~50-60 days after birth) in this mouse model.

10 Among LS patients, approximately 18-21% have cardiac involvement and this is associated with a worse  
11 prognosis. Cardiac abnormalities in LS may include cardiomyopathy, pericardial effusion, and conduction  
12 abnormalities. Hypertrophic cardiomyopathy has been reported as the most common abnormality in these  
13 patients (3-4). In *Ndufs4*<sup>-/-</sup> mouse models, while the encephalomyopathy is unequivocal, cardiac involvement  
14 remains debatable. In two independent studies describing mice with cardiac-specific *Ndufs4* deletion, one  
15 showed hypertrophic cardiomyopathy (5), while the other reported normal cardiac function (6).

16 In the present study, we sought to elucidate the metabolic derangement and underlying mechanisms of  
17 cardio-encephalomyopathy in LS using germline *Ndufs4*<sup>-/-</sup> mice (*henceforth referred to as LS mice*). We found  
18 that these mice develop severe bradyarrhythmia and diastolic dysfunction due to hyperacetylation of the cardiac  
19 sodium channel (Nav1.5) and the calcium handling protein sarco/endoplasmic reticulum Ca<sup>2+</sup>-ATPase 2a  
20 (SERCA2a), respectively. We also discovered that supplementation with nicotinamide riboside (NR) (7)  
21 increased intracellular NAD<sup>+</sup>, reversed protein hyperacetylation, ameliorated metabolic derangement, restored  
22 sinus rhythm, normalized diastolic function, ameliorated the decreases in Nav1.5 current and restored SERCA2  
23 function in LS mice and human iPS-CMs with homozygous *Ndufs4* deletion. We further demonstrate that NR  
24 attenuates acetyl-p53-mediated neuronal apoptosis in LS mouse brain (cerebellum and midbrain) and iPS-

derived mixed neurons with the Ndufs4 deletion. These data provide a mechanistic explanation for the pathophysiology of LS cardio-encephalomyopathy and its underlying metabolic derangement.

## RESULTS

### Metabolic derangement in LS is partially restored by Nicotinamide Riboside

We performed multiple targeted metabolomics analyses to investigate changes of several metabolites in the LS heart and brainstem/cerebellum. We focused on brainstem and cerebellum since these regions have the most prominent brain pathologies and can be quickly dissected and flash-frozen to preserve tissue metabolites. The metabolomic dataset is presented in Supplemental Table 1 (1<sup>st</sup>, WT vs. LS hearts), Supplemental Table 2 (2<sup>nd</sup>, WT vs. LS vs. NR-treated LS hearts), Supplemental Table 3 (2<sup>nd</sup>, WT vs. LS vs. NR-treated LS brainstem and cerebella) and is summarized in Figure 1a-b. The most prominent findings were significant increases in many amino acids (ranged from +36% to >3-fold increase in both hearts and brains), urea and metabolic derivatives of branched-chain amino acid (BCAA) aminotransferase, including  $\alpha$ -keto-isocaproate and  $\beta$  hydroxy- $\beta$ -methylbutyric acid (both from leucine),  $\alpha$ -ketoisovalerate (KIV, from valine) and  $\alpha$ -keto- $\beta$ -methylvaleric acid (KMV, from isoleucine). These  $\alpha$ -keto-derivatives of BCAA usually undergo oxidation by branched-chain  $\alpha$ -keto acid dehydrogenases (BCKD), key enzymes requiring  $NAD^+$  as a cofactor. BCKD enzymes were likely impaired because of decreased  $NAD^+/NADH$  in LS hearts and brains. There were accumulation of some TCA cycle intermediates, including citrate, aconitate, and isocitrate, which is likely related to impaired activity of the  $NAD^+$ -dependent enzyme isocitrate dehydrogenase. Arachidonate, a critical signaling molecule and a precursor of various eicosanoids (such as prostaglandins, etc.), was increased. There were decreases in niacin (a precursor of  $NAD^+$ ), tyrosine and mannose (only in the heart). NR supplementation (500mg/Kg/day, i.p.) significantly reversed and restored many of these metabolomics changes associated with Ndufs4 deficiency in both cerebellum/brainstem and heart (Figure 1a-b). There were no significant and consistent changes in glycolytic, pentose phosphate pathways, purine, or pyrimidine metabolites.

Using liquid chromatography followed by mass spectrometry analysis of these samples, we demonstrated that *Ndufs4* deletion (which results in the deficiency of NADH Dehydrogenase) led to decreased  $\text{NAD}^+/\text{NADH}$  (Figure 1c). In addition, there was substantial depletion of the reduced form of glutathione (GSH), a major intracellular antioxidant system, in LS hearts and cerebellum. NR supplementation significantly rescued  $\text{NAD}^+/\text{NADH}$  and restored GSH levels in LS hearts and brains (Figure 1c), thereby ameliorated many metabolic defects due to  $\text{NAD}^+$  deficiency and redox stress (Figure 1a-b).

### ***Ndufs4*<sup>-/-</sup> mice (LS mice) were runted and had cardiomyopathy**

Echocardiography of conscious mice showed that left ventricle (LV) mass and ejection fraction were normal in LS mice (Figure 2a-b), but tissue Doppler imaging showed that diastolic function was impaired (Figure 2c), as evidenced by decreased ratio of relaxation velocity of mitral annulus during early diastole (E') to late diastole (A'). In addition, these mice had severe bradycardia, with a median resting heart rate (HR) of ~400 bpm (Figure 2d), reflecting a ~35% decrease from the baseline physiological HR of >600 bpm. Both diastolic dysfunction and bradyarrhythmia were significantly ameliorated by supplementation with NR (500mg/Kg/day, i.p.) (Figure 2c-d). LS mice were runted, with their average body weight ~60% that of wild type (WT) littermates, and NR supplementation did not alter this (Supplemental Figure 1a). Heart weight and heart weight normalized to tibia length did not differ significantly from that in WT mice, and this was not affected by NR supplementation (Supplemental Figure 1b-c). Pathological analysis assessing ventricular size and fibrosis did not distinguish between hearts from WT mice and their LS counterparts with or without NR treatment (Supplemental Figure 1d-g).

Electrocardiograms (ECGs) from conscious immobilized LS mice demonstrate a spectrum of bradyarrhythmia. These include occasional second-degree atrioventricular (AV) block (red arrow, Figure 2e), rare high-grade AV block (Figure 2f), and frequent sinus node dysfunction (Figure 2g). Bradyarrhythmia were frequently recorded in LS mice (Figure 2h). Supplementation with NR substantially reduced arrhythmic events in LS mice (Figure 2h).

## Hyperacetylation of Nav1.5 promote bradyarrhythmia in LS mice

To exclude autonomic dysfunction or metabolic acidosis as potential contributors to the bradyarrhythmia observed in LS mice, we dissected sinoatrial nodal (SAN) tissue, loaded it with the Rhod-2 calcium indicator dye *ex vivo*, and assessed calcium transients by confocal microscopy. In LS SAN tissue, there were multiple long pauses in spontaneous  $[Ca^{2+}]$  transients, suggesting SA nodal pauses (Figure 3b). NR supplementation significantly reduced the bradycardic events and restored sinus rhythm (Figure 3c-d) to frequencies and amplitudes similar to those recorded from WT SAN samples (Figure 3a). Fibrosis assessed by Trichome stain was not different in WT SAN, LS SAN or LS SAN treated with NR (Figure 3e-g).

To address whether cell-autonomous mechanism is sufficient to cause arrhythmia, we crossed *Ndufs4*<sup>flox/flox</sup> mice with HCN4-Cre mice to generate conduction tissue-specific deletion of *Ndufs4*. Approximately 2-3 months after tamoxifen-induced deletion of *Ndufs4*, 87.5% of the HCN4-*Ndufs4*<sup>-/-</sup> mice developed various forms of arrhythmia, including atrial or ventricular premature contractions, sinus bradyarrhythmia and frequent sinus pauses resembling those found in germline *Ndufs4*<sup>-/-</sup> LS mice (Supplemental Figure 2a-c). This finding supports the hypothesis that *Ndufs4* deficiency in the cardiac conduction system itself is sufficient to cause arrhythmia in a cell-autonomous manner, although the metabolic defect of *Ndufs4*<sup>-/-</sup> in neurons, cardiomyocytes, and other cell types could also contribute to arrhythmia by impacting the neurohormonal or paracrine regulation of cardiac rhythm.

*Ndufs4* deletion (which results in the deficiency of NADH Dehydrogenase) led to reduced  $NAD^+/NADH$  (Figure 1c), a change that can impair the function of  $NAD^+$ -dependent enzymes, including Sirt1(8). To identify potential mechanisms responsible for the arrhythmia and diastolic dysfunction in LS mice, we examined the cardiac sodium channel *Nav1.5* and *SERCA2a*, respectively. *Nav1.5* governs the initiation and propagation of the cardiac action potential, whereas *SERCA2a* is the key protein regulating the decay of calcium transients by reuptake into sarcoplasmic reticulum. Both proteins are reported to be modulated by Sirt1<sup>9,10</sup>. We have previously shown that acetylation of the K1479 residue in *Nav1.5* impairs the trafficking of this channel protein,

causing a decrease in the inward depolarizing  $\text{Na}^+$  current ( $I_{\text{Na}}$ ) conducted by this channel. To examine the role of acetylation in LS hearts, we performed immunohistochemistry using an antibody specific for acetylation of  $\text{Na}_v1.5$  at K1479 modification and showed that K1479 in  $\text{Na}_v1.5$  was significantly hyperacetylated in both the SAN and LV from LS hearts (Figure 3i, Supplemental Figure 3a-b). NR supplementation dramatically reversed this acetylation in both SAN and LV in LS mouse hearts (Figure 3j, Supplemental Figure 3c), concomitant with the observed amelioration of arrhythmia and restoration of the normal sinus rhythm (Figure 3a-c). For quantitative analysis, we performed immunoprecipitation with acetyl-lysine antibody and demonstrated that the acetylated forms of  $\text{Na}_v1.5$  and SERCA2a were substantially increased in LS hearts. The acetylated  $\text{Na}_v1.5$  and SERCA2a were significantly attenuated by NR supplementation (Figure 3k, m), while the total levels of both the  $\text{Na}_v1.5$  and SERCA2a proteins did not differ significantly among any groups (Figure 3l, n).

### **Acetylation of K1479 of $\text{Na}_v1.5$ in mitochondrial complex I -deficient cells decreases the inward depolarizing $\text{Na}^+$ current**

To further investigate the role of K1479 acetylation in  $\text{Na}_v1.5$  in the context of mitochondrial complex I deficiency, we used HEK293 cells heterologous expression system. Since the endogenous  $\text{Na}_v1.5$  expression in HEK293 is negligible, we can investigate  $\text{Na}_v1.5$  by introducing exogenous wild-type or K1479 mutant (Figure 4a). We generated *Ndufs4* and *Ndufs2* knock-out (KO) HEK 293 cells using the CRISPR/Cas9 method, followed by transfection with WT or K1479 mutant  $\text{Na}_v1.5$ , as confirmed by Western blots (Figure 4a). Notably, the deletion of *Ndufs2* also resulted in a substantial decrease in *Ndufs4* expression. Given that mitochondrial complex I is a large respiratory complex and *Ndufs2* is located adjacent to the junction of the inner membrane and matrix domain, we proposed that its loss destabilized the matrix domain leading to degradation of the *Ndufs4* subunit. As expected, in light of the loss of both subunits in the *Ndufs2* KO cells, the phenotype was more severe than that of the *Ndufs4* KO cells. Analysis of the conditioned media from these two cell lines and control cells, revealed that by 24 hours, the *Ndufs2* KO cells developed a significantly more acidic environment (pH ~7.2) than WT cells (pH ~7.7,  $p=0.023$ ), while the media from the *Ndufs4* KO cells did not

1 become significantly acidic until 48 hours (pH of ~6.9) compared to WT cells (pH ~7.3,  $p=0.01$ ) and remained  
2 less acidic than Ndufs2 KO media (pH ~6.5,  $p=0.006$ , Figure 4b). Immunoblotting confirmed elevated protein  
3 acetylation of total protein from Ndufs2KO cell lysate (Supplemental Figure 3d).

4 Live-cell staining with a marker of mitochondrial respiratory activity, tetramethylrhodamine, ethyl ester  
5 (TMRE), and a marker of reactive oxygen species (ROS), 2',7'-dichlorodihydrofluorescein diacetate (DCFDA),  
6 showed reduced TMRE in Ndufs4 KO cells, indicating that mitochondrial membrane potential was decreased.  
7 Conversely, DCFDA fluorescence was increased, suggesting that total cellular ROS levels were higher (Figure  
8 4c, e). Ndufs2 KO cells displayed a much greater loss of mitochondrial membrane potential and a greater  
9 increase in cellular ROS than the Ndufs4KO cells, and this was significantly ameliorated upon NR  
10 supplementation (Figure 4c, e). Immunofluorescence staining with an antibody specific for acetylated K1479  
11 (Ac-K1479) in Nav1.5 revealed a ~2-fold increase in acetylation in Ndufs4 KO cells and a ~4-fold increase in  
12 Ndufs2 KO cells, which was significantly decreased after NR supplementation (Figure 4d, f). To determine the  
13 functional relevance of Nav1.5 hyperacetylation on this residue, we performed a patch-clamp experiment on the  
14 WT and Ndufs2 KO cells. The inward depolarizing  $\text{Na}^+$  current ( $I_{\text{Na}}$ ) was significantly lower in the Ndufs2 KO  
15 cells (Figure 4g-i), as shown by the  $I_{\text{Na}}$  at -35mV and the area under the current-voltage curves (AUC).  
16 Consistent with the contribution of Nav1.5 hyperacetylation (Figure 4d, f), pre-treatment with NR for 24hrs  
17 significantly restored  $I_{\text{Na}}$  in Ndufs2 KO cells and potentiated the  $I_{\text{Na}}$  of WT control cells (Figure 4g-i).

18 To further investigate the importance of K1479-Nav1.5 acetylation status on the  $\text{Na}^+$ -current phenotype of  
19 Ndufs2KO cells, we transfected HEK293 cells with a lysine to glutamine mutant construct, K1479Q-Nav1.5,  
20 that mimics constitutively acetylated K1479 Nav1.5, which we previously showed to have decreased  $I_{\text{Na}}$  (9).  
21 Interestingly, when the K1479Q-Nav1.5 was expressed in Ndufs2 knock-out HEK293 cells, no further decrease  
22 in  $I_{\text{Na}}$  was observed compared with wild-type Nav1.5 in these Ndufs2KO cells (Supplemental Figure 4a-b).  
23 These data indicate that acetylated K1479 Nav1.5 in these Ndufs2KO cells decreased  $I_{\text{Na}}$  to a similar extent as  
24 acetylation mimics K1479Q Nav1.5, suggesting a similar mechanism for both. While NR supplementation  
25 increased  $I_{\text{Na}}$  conducted by wild-type Nav1.5 (Figure 4h), the acetylation mimic K1479Q-Nav1.5 did not

respond to NR in Ndufs2 KO cells (Supplemental Figure 4a-b). Since the K1479Q-Nav1.5 that mimics the persistent acetylated state led to decreased  $I_{Na}$  and did not respond to NR supplementation, these results support the hypothesis that acetylation of Nav1.5 at K1479 contributes to decreased  $I_{Na}$  induced by Ndufs2 deletion and that deacetylation by NR enhances  $I_{Na}$ . To investigate whether the enhanced  $Na^+$  current phenotype by NR is mediated through Sirt1, we treated wild-type HEK293 cells expressing Nav1.5 with the Sirt1 inhibitor, Ex-527<sup>9,11</sup>. Our results showed that Ex-527 blocked the NR-mediated enhancement of  $I_{Na}$  (Supplemental Figure 4 c-d), suggesting that the NR effect is mediated, at least in part, by the  $NAD^+$ -dependent enzyme Sirt1.

### **NR ameliorates LS mice activity, neuronal apoptosis and microgliosis**

Measurements performed in metabolic chambers showed that the LS mice had impaired motor function, characterized by cerebellar ataxia, and decreased locomotor activity (Figure 5a). Energy expenditure (heat production) and respiratory exchange ratio (RER) were lower in LS vs. WT mice (Figure 5b-c). These changes in energy expenditure were not significantly affected by NR. However, NR supplementation significantly ameliorated the ataxia (see Expanded View movies) and improved daily locomotor activity (Figure 5a). Neuropathological examination of the LS brain demonstrated spongiosis, defined as edema of neuropils (Figure 5d), and proliferation of microglia and vascular cells (Figure 5e, red arrow), particularly in the cerebellum and the brainstem region. Semiquantitative analysis of hematoxylin and eosin (H&E)-stained LS brain sections by a neuropathologist blinded to treatment group revealed increased foci of these lesions in the LS mice but none in NR-treated LS counterparts (Figure 5f). Quantitative analysis of Purkinje cell density in the cerebellar cortex showed a significant reduction of Purkinje cells in the LS mice, indicating that neurons were lost (Figure 5g, i), and this was attenuated by NR treatment (Figure. 5h-i).

Immunohistochemistry for cleaved-caspase-3 revealed prominent apoptosis among cells of the Purkinje layer and the underlying granular neurons in the cerebellum of untreated LS mice (Figure 5k, m). Apoptotic cells were scattered throughout the cerebral cortex in LS mice (Figure 5o, q). Apoptosis was associated with prominent activation of microglia, as the number of Iba-1 positive microglia in the dorsal midbrain (Figure 5s)

and cerebellar cortex (Figure 5s inset) were significantly higher in the LS mice. Treatment with NR significantly mitigated neuronal apoptosis in both the cerebral cortex and dorsal midbrain (Figure 5l-m, 5p-q), and the associated activation of microglia in the LS brain (Figure 5t-u). Consistent with neuroprotective and cardioprotective effects, NR significantly extended the lifespan of LS mice (Supplemental Figure 5). Interestingly, although *Ndufs4*<sup>-/-</sup> promoted apoptosis in the susceptible neurons of the cerebellar and brainstem regions, it did not induce apoptosis in cardiac left ventricular tissue (Supplemental Figure 6).

### **Deletion of *Ndufs4* decreased *Nav*1.5 current in human iPS-derived cardiomyocytes**

To increase the translational relevance of our findings in mice and heterologous cells (HEK293), we deleted the *Ndufs4* subunit using the CRISPR/Cas9 method in human iPS cells generated from a healthy Caucasian male (ATCC-1026). We confirmed that deletion of *Ndufs4* was successful by Western blotting (Figure 6a) and immunostaining of the iPS-Cardiomyocytes (iPS-CMs) (Figure 6b). We performed live-cell staining of isogenic control and *Ndufs4* KO iPS-CMs at ~30 days post-differentiation. The presence of *Ndufs4* staining in iPS-CM at this stage is confirmed by colocalization of Troponin staining in control iPS-CM (Supplemental Figure 7). *Ndufs4* KO cells had less TMRE staining (loss of red) and more DCFDA staining (green) than control iPS-CMs, and this was mitigated by pre-treatment with NR (1mM) for 24 hours (Figure 6c-d). These findings suggest that *Ndufs4* KO cells have a lower mitochondrial membrane potential and higher levels of cellular ROS than WT counterparts (Figure 6c-d), and that pre-treatment with NR mitigates these effects. Paced at 0.5 Hz, we measured  $\text{Ca}^{2+}$  transients in these iPS-CMs and found that *Ndufs4* KO cells had a substantially slower decay rate (longer T50, time to 50% from peak) when compared with isogenic iPS-CM control ( $p < 0.001$ ) and this was significantly improved by NR ( $p < 0.001$ , Figure 6e [right panel] and 6f). The amplitude of  $\text{Ca}^{2+}$  transients was not significantly different among all three groups (Fig 6e [left panel] and 6f). These findings suggest slower SERCA2  $\text{Ca}^{2+}$  reuptake in *Ndufs4* KO iPS-CM, that is significantly ameliorated by NR treatment. To confirm the findings in HEK293 cells, we performed patch-clamp to measure the inward depolarizing  $\text{Na}^+$  current ( $I_{\text{Na}}$ ) in *Ndufs4* KO iPS-CMs and its isogenic control. As shown by the current-voltage curves (Figure 6g),  $I_{\text{Na}}$

density at -15 mV (Figure 6h) and area under the curve (AUC) of  $I_{Na}$  -voltage curves (Figure 6i), *Ndufs4* knock-out reduced  $I_{Na}$  by ~45% ( $p=0.088$  for  $I_{Na}$  at -15mV and  $p=0.04$  for AUC of current-voltage curves, Figure 6h-i). Pre-treatment with NR for 24 hours significantly enhanced  $I_{Na}$ , especially in the *Ndufs4* KO iPS-CMs (Figure 6g-i).

## Increased p53 acetylation and apoptosis in the *Ndufs4*-deficient brain

Our finding of enhanced apoptosis in the cerebellum and brainstem of *Ndufs4*<sup>-/-</sup> mice and that this effect was ameliorated by NR supplementation (Figure 5j-u) suggested that protein hyperacetylation plays a critical role in apoptosis in the susceptible brain regions. Given that acetylation of p53 has been shown to enhance apoptosis (12), we examined iPS-derived neurons (iPS-N) for dysregulated  $NAD^+$ /NADH and impaired Sirt1-dependent deacetylation of p53, which might potentially lead to neuronal apoptosis. *Ndufs4* knock-out iPS and isogenic iPS controls were differentiated into neuronal progenitor cells (NPCs), which were then stimulated to form neural rosettes using an embryoid-body-based method (STEMCELL). The NPCs were allowed to mature into a mixed population of cells expressing a marker of GABAergic (the vesicular GABA transporter, VGAT in green, Figure 7a) or glutamatergic (vesicular glutamate transporter 1, VGLUT1, in green, Figure 7b) neurons. These VGAT or VGLUT1 markers colocalized with the pan-neuronal marker beta-3 tubulin, Tu-20 (Figure 7a-b red), indicating a mixed population of iPS-Ns. At ~30 days post-differentiation from neural rosettes (Figure 7c), these mixed iPS-Ns were stimulated with glutamate (30  $\mu$ M), with or without NR (1 mM). The effect of glutamatergic excitotoxicity after 24 hours was assessed by TUNEL assay and measurement of acetyl-p53 (Figure 7d-e). Acetylation of p53 at either lysine K120 or K382 promotes p53-dependent apoptosis<sup>12,13</sup> in response to DNA damage, cell stress, and oncogenic stress (14). Glutamate excitotoxicity led to a significant induction of apoptosis (TUNEL staining) in control iPS-Ns, in parallel with an increase in p53 acetylation ( $p=0.003$ ). NR treatment with or without Ex-527, an inhibitor of Sirt1, in control iPS-Ns stimulated with glutamate did not significantly alter TUNEL or acetylated p53 staining (Figure 7d, f). In contrast, the glutamate excitotoxicity was potentiated in *Ndufs4* KO iPS-Ns, shown by substantial increases in both TUNEL and Ac-

p53 in response to glutamate stimulation ( $p < 0.001$ , Figure 7e-f). Treatment with NR significantly attenuated the potentiation of p53 acetylation and TUNEL positivity in response to glutamate toxicity in the Ndufs4 KO iPS-N cells. Simultaneous treatment with Ex-527 and NR significantly attenuated the protective effect of NR on glutamate toxicity in Ndufs4 KO iPS-N cells. The partial inhibition of NR beneficial effect by Ex-527 suggests that the anti-apoptotic effect is mediated, at least in part, by NR-dependent Sirt1 deacetylation of p53. To confirm these findings *in vivo*, we performed Western blots of K120 acetylated-p53 in cerebellar/midbrain lysates. Acetylated p53 at K382 and K120 residues in cerebellar lysates from Ndufs4<sup>-/-</sup> mice were increased compared with those from WT mice (Figure 7g, Supplemental Figure 8a-c). NR supplementation significantly reduced the hyperacetylation of p53, concomitant with the amelioration of neuronal apoptosis (Figure 5j-q).

## DISCUSSION

This study demonstrates novel mechanisms underlying cardio-encephalomyopathy in LS. Our analysis of mouse and iPS-CM models of this disease revealed that hyperacetylation of Na<sub>v</sub>1.5 promotes bradyarrhythmia and hyperacetylation of SERCA2a contributes to diastolic dysfunction. We further showed that the reversal of hyperacetylation by NR supplementation ameliorates these cardiomyocyte abnormalities in the context of Ndufs4 deficiency, *in vivo* and *in vitro*. Our study also provides a novel mechanistic explanation for the loss of neurons in LS, with involvement of p53 hyperacetylation and increased apoptosis in cerebellar and midbrain regions. Using targeted metabolomics, we demonstrated metabolic alterations in LS hearts and cerebellum/brainstem, characterized by significant increase in many amino acids and their metabolic derivatives, arachidonate and accumulation of TCA cycle intermediates (citrate, aconitate and isocitrate), decreased glutathione, niacin, and NAD<sup>+</sup>. We further showed that NR restores intracellular NAD<sup>+</sup>, glutathione and many of these metabolic changes. NR also attenuated p53 acetylation in iPS-Ns and the cerebellum and midbrain of LS mice, leading to an attenuation of neuronal apoptosis and mitigation of neuropathological lesions in LS brain.

Previous studies using germline LS mice focused largely on encephalomyopathy phenotypes(2). However, in clinical settings, ~18-21% of LS patients have cardiac pathology, including hypertrophic cardiomyopathy and/or conduction abnormalities(3)(4). Thus, it is important to understand the cardiac manifestations in LS mice, which are not well characterized. Previous studies have utilized various muscle-specific loss of *Ndufs4* to elucidate the role of mitochondrial complex I in cardiac physiology and metabolism. Although myocyte-specific loss of *Ndufs4* (driven by CKM-NLS-Cre)(5) had been shown to lead to hypertrophic cardiomyopathy, cardiomyocyte-specific loss of *Ndufs4* (driven by  $\alpha$ MHC) did not show significant structural abnormalities or systolic dysfunction. Interestingly, in the latter group, pressure-overload induced heart failure was found to be aggravated(6) and associated with increased protein hyperacetylation due to alterations in the redox state and inhibition of Sirt3 activity(6). However, a more recent study of these mice (from the same group) showed that *ex vivo* ischemia-reperfusion injury was ameliorated in these mice, involved with a reduction of ROS, suggesting that ROS arising during reperfusion injury is generated mainly by complex I (15).

This study elucidates novel mechanisms that contribute to several phenotypes of cardio-encephalomyopathy in LS mice. First, we reported a novel finding of severe bradyarrhythmia, including SAN dysfunction (sick sinus syndrome) and occasional heart block that were associated with hyperacetylation of the K1479 in *Nav1.5*. *Nav1.5* is expressed in the ventricular myocardium (16) and in the periphery of the sinoatrial node in which it is involved in the propagation of the action potential (17). Deletion of *Ndufs* subunits in heterologous system (HEK293) and iPS-CMs impaired various  $\text{NAD}^+$ -dependent sirtuin deacetylases(9). Our previous study showed that membrane trafficking of *Nav1.5* is disrupted by hyperacetylation of the K1479 residue in *Nav1.5* in *Sirt1*<sup>-/-</sup> mice, and this leads to reduced  $I_{\text{Na}}$  and impaired electrical activity in the heart (9). This study is the first to link mitochondrial complex I deficiency and the mechanisms underlying bradyarrhythmia with reduced  $\text{NAD}^+/\text{NADH}$ , which leads to hyperacetylation of K1479 in *Nav1.5* and subsequent reduction of the  $I_{\text{Na}}$ , resembling the conduction block seen in MHC-*Sirt1*<sup>-/-</sup> mice. The fact that NR reversed hyperacetylation of *Nav1.5* at K1479 and enhanced  $I_{\text{Na}}$  in concert with restoration of normal sinus rhythm suggests that the hyperacetylation of *Nav1.5* leads to bradyarrhythmia in the context of *Ndufs4* deletion in LS hearts (Figure 8).

1 In addition to Sirt1-dependent Nav1.5 acetylation, our previous study showed an acetylation-independent  
 2 increase in  $I_{Na}$  by NR supplementation through PKC phosphorylation of Nav1.5 (10)(18). Furthermore, a defect  
 3 in mitochondrial complex I may also trigger oxidative and/or reductive stress (19), which has been shown to  
 4 slow Nav1.5 inactivation, and/or to decrease the peak  $I_{Na}$ , leading to arrhythmia (20)(21). Our mass  
 5 spectrometric analysis in LS mouse hearts showed substantial reductions in reduced glutathione (GSH), a major  
 6 reducing substrate in the endogenous antioxidant system, which was also restored by NR supplementation,  
 7 suggesting that the beneficial effect of NR may also be mediated, at least in part, by restoring GSH (Figure 1c).

8 The second finding in our study that sheds light on LS-associated cardiomyopathy is that, despite the  
 9 absence of hypertrophic cardiomyopathy or systolic dysfunction, LS mice exhibited significant diastolic  
 10 dysfunction in association with hyperacetylation of SERCA2a. Hyperacetylation of SERCA2a was recently  
 11 shown to reduce  $Ca^{2+}$  reuptake into SR (i.e., SERCA2a dysfunction) (22), predisposing to the development of  
 12 heart failure. Increased SERCA2a acetylation was also reported in various failing heart samples, including end-  
 13 stage human cardiac explants, murine hearts with pressure-overload induced heart failure, and porcine models  
 14 of myocardial infarction. These observations suggest that increased acetylation of SERCA2a might be a shared  
 15 mechanism leading to impaired SERCA2a function in failing hearts (22). Our finding that NR reversed the  
 16 hyperacetylation of SERCA2a and ameliorated its compromised function in LS mouse hearts and Ndufs4-  
 17 deficient iPS-CMs suggests that SERCA2a hyperacetylation may contribute to diastolic dysfunction in LS mice.

18 The third key finding in our study of LS-encephalomyopathy is the substantial loss of neurons, increased  
 19 neuronal apoptosis and increased infiltration of the cerebellum and midbrain by activated microglia,  
 20 concomitant with an increase in acetylated-p53. Acetylation of p53 has been shown to mediate activation of the  
 21 downstream effector p21, leading to apoptosis (14). Our demonstration of the beneficial effects of NR in  
 22 decreasing acetylated-p53 and neuronal apoptosis (both *in vitro* and *in vivo*), including attenuating microglial  
 23 activation and overall neuropathology in the LS mouse brain, suggests that activation/hyperacetylation of the  
 24 p53-mediated apoptotic pathway contributes to the severe encephalopathy observed in LS mice (Figure 8).

25 Mechanistically, Sirt1-mediated deacetylation of p53 inactivates the sequence-specific transcriptional activity of

the protein and represses p53-mediated arrest of cell growth and apoptosis in response to DNA damage and oxidative stress. This process also prevented p53-dependent transactivation of p21 (23). Several lysines in human p53 (K120, K370, K372, K373, K381, K382) are acetylated following various forms of DNA damage, enhancing the transcriptional activity of p53 and regulating the fate of the cell (13). As we have shown, acetylation of p53 at K120, within its DNA-binding domain, is crucial for p53-mediated apoptosis. Our findings are reinforced by a previous study demonstrating that Sirt1 plays a neuroprotective role in the context of brain ischemia through deacetylation and subsequent inhibition of p53-induced and nuclear factor  $\kappa$ B-induced apoptotic and inflammatory pathways (24). Similarly, the Sirt1 mediated brain-protective effect of Maresin1 (macrophage mediator in resolving inflammation) in a mouse model subjected to middle cerebral artery occlusion demonstrates the involvement of Sirt1 signaling in the reduction of mitochondrial damage in the context of cerebral ischemia reperfusion injury (25).

The role of protein hyperacetylation in heart failure has been controversial. Increased global, mitochondrial, and metabolic protein acetylation has been documented in  $\alpha$ MHC-Ndufs4<sup>-/-</sup> mouse hearts, human heart failure and several experimental models, suggesting protein hyperacetylation is critical in the pathogenesis of heart failure. In contrast, a recent study showed that extreme acetylation of the cardiac mitochondrial proteome in carnitine acetyltransferase and Sirt3 double knock-out (DKO) mice did not potentiate pressure-overload induced heart failure. Even though the mitochondrial acetyl-lysine landscape of these DKO hearts was elevated to levels much higher than those observed in response to pressure overload or Sirt3 KO alone, deep phenotyping of mitochondrial function in the DKO revealed a surprisingly normal bioenergetics profile (26). The current study provides a direct mechanistic link between mitochondrial dysfunction and cardiomyopathic phenotypes caused by impairment of Sirt1 due to NAD<sup>+</sup> deficiency. Our studies of LS mice elucidate a mechanism that underlies bradyarrhythmia and diastolic dysfunction which is promoted by hyperacetylation of Nav1.5 and SERCA2a, respectively. Both Nav1.5 and SERCA2a are critical cardiac proteins and well-known targets of Sirt1, rather than the targets of mitochondrial Sirt3. Collectively, our findings and previous publications suggest that it is the

1 protein targets of acetylation themselves, rather than the degree of global protein acetylation, that play a critical  
2 role in cardiomyopathic phenotypes.

3 The fourth key finding is significant increase in many amino acids and certain TCA intermediates (citrate,  
4 aconitate, and isocitrate) in affected LS tissues, including cerebellum/brainstem and heart by targeted  
5 metabolomics. These are likely due to the impairment of various  $\text{NAD}^+$ -dependent dehydrogenases, such as  
6 isocitrate dehydrogenase, of which the impairment may contribute to the accumulation of isocitrate, aconitate,  
7 and citrate. Likewise, decreased  $\text{NAD}^+/\text{NADH}$  in LS may impair  $\text{NAD}^+$ -dependent BCKD, which is responsible  
8 for BCAA oxidation, leading to accumulation of BCAAs (Figure 1a). NR supplementation significantly  
9 increased the  $\text{NAD}^+$  levels, decreased  $\text{NAD}^+/\text{NADH}$ , and restored the metabolic derangement in LS  
10 cerebellum/brainstem and heart. Interestingly, several amino acids, particularly BCAAs, are potent inducers of  
11 the mechanistic target of the rapamycin (mTOR) signaling pathway, which has been shown to be activated in  
12 the LS brain, in concert with increased amino acids in the brainstem (27). Rapamycin, a specific inhibitor of  
13 mTOR, robustly enhances survival and attenuates disease progression. For example, it delays the onset of  
14 neurological symptoms, reduces neuroinflammation, and prevents brain lesions in these LS mice (28). A recent  
15 study reported that rapamycin restored mitochondrial protein levels and reduced the abundance and activity of  
16 multiple PKC isoforms in whole brain lysates of LS mice (29). Indeed, in a small clinical study, the  
17 mitochondrial disease phenotypes of four kidney transplant patients with mitochondrial disease (MELAS)  
18 improved after the immunosuppressant was replaced with rapamycin to achieve mTOR inhibition (30).  
19 However, because rapamycin is an immunosuppressant, the application to treat mitochondrial diseases might be  
20 limited by its side effects.

21 A few treatment options have been proposed to alleviate LS pathologies in the same mouse model used in  
22 this study. Apart from rapamycin, chronic hypoxia has been shown to improve survival, body weight, body  
23 temperature, behavior, neuropathology, disease biomarkers and brain  $\text{NAD}^+$  concentration (31) in LS mice. In  
24 these studies, chronic hypoxia was achieved by putting the LS mice in a hypoxic chamber (32) or inducing  
25 severe anemia by phlebotomy or inhaling low-dose carbon monoxide (33). Although these proof-of-concept

approaches are interesting, the clinical translation of these therapeutics may be challenging. A recent study using nicotinamide mononucleotide, NMN, also showed that this agent extended the lifespan of *Ndufs4*<sup>flox/flox</sup> Meox2-Cre mice by restoring the NAD<sup>+</sup> redox balance and lowering the accumulation of hypoxia-inducible factor 1-alpha in the skeletal muscle of *Ndufs4* KO mice (34). However, no apparent beneficial effects were observed in the brain. Our current study elucidates the mechanism underlying the NR-mediated improvement of encephalopathy in *Ndufs4*KO mice, i.e., deacetylation of p53, and thus inactivation of the p53-dependent apoptotic pathway, leading to attenuation of neuronal apoptosis and the reduction of microglial activation in the cerebellum and the brainstem region.

The current study is the first to apply human iPS-CMs and iPS-Ns to model LS cardio-encephalomyopathy to elucidate mechanisms responsible for arrhythmia, diastolic dysfunction, and neuronal apoptosis. Using *Ndufs4* KO iPS-CMs, we show that *I*<sub>Na</sub> and SERCA2a function is decreased in these cells, and that these effects can be prevented by NR treatment. In iPS-Ns, *Ndufs4* deficiency led to hyperacetylation of p53, resulting in increased neuronal apoptosis. The application of iPS modeling to human diseases has great potential to achieve the translation potential of personalized medicine and test the patient-specific efficacy of novel therapeutics. Given that NR is a vitamin B3 supplement with excellent safety profiles (35), our study provides robust evidence to support the potential clinical use of NR in LS patients.

## METHODS

**Study design.** This study was designed to identify the mechanisms underlying cardio-encephalomyopathy in LS mice (germline *Ndufs4*<sup>-/-</sup> deletion). Our hypothesis was tested both *in vitro* and *in vivo* using mice and human iPS cells modeling LS. Mice included germline *Ndufs4*<sup>-/-</sup> (LS mice) and conduction tissue-specific *Ndufs4*<sup>-/-</sup> (driven by HCN4-CRE). Six to 12 mice in each group were used to achieve a power of 0.8, with significance defined as p<0.05. The sample size per experiment is included in each figure legend. 21-30-days-old *Ndufs4*<sup>-/-</sup> mice of both genders were given daily intraperitoneal NR injection (500mg/Kg/day) for 3-4 weeks.

1 For the *in vitro* studies, we used human embryonic kidney 293 (HEK293) cells and human iPS cells generated  
2 from a healthy Caucasian male (ATCC-1026) followed by deletion of *Ndufs4* using the CRISPR/Cas9 method.

3 **Animal models.** Germline *Ndufs4*<sup>-/-</sup> mice were obtained from the University of Washington (2). The  
4 HCN4-*Ndufs4* mice were generated by crossing *Ndufs4*<sup>flox/flox</sup> mice with *Hcn4*tm2.1 (cre/ERT2) Sev/J mice  
5 (provided by Dr. Ivan Moskowitz, University of Chicago, available at JAX, # 024283 | HCN4CreERT2). All  
6 mice were on the C57/BL6/J background and were fed the regular diet from Harlan Teklad.

7 **Cell culture.** HEK293 cells were obtained from the American Type Culture Collection (ATCC, Manassas,  
8 VA) and were cultured in 10% FBS and 1% PenStrep-supplemented DMEM medium.

9 **Generation of *Ndufs* knock-out cells using the CRISPR/Cas9 method.** HEK293 cells were cultured to  
10 70-80% confluence in 6-cm dishes. Cells were transfected with 2.5 µg of NF2SgRNA or NF4SgRNA  
11 (Addgene) and 5 µl of Lipofectamine 2000 (Invitrogen). Forty-eight hours after transfection, the cells were  
12 treated with the appropriate drug and selection was carried out for ~7 days. The cells were then dissociated to  
13 single cells. After cells were counted, they were diluted serially in DMEM medium + 10% FBS to a final  
14 concentration of 5 cells per one well of 96-well plates and expanded for 2-3 weeks. Visible colonies were  
15 picked and reseeded in new wells for monolayer growth. Positive candidates were validated by western blotting.

16 **Maintenance of human iPS cells and differentiation of cardiomyocytes and neurons.** Human iPS cells  
17 were cultured on Matrigel-coated plates (Corning, Life Sciences) and fed with a mixture of SFM and mTeSR<sup>+</sup>  
18 at a ratio of 75%:25%. For cardiomyocyte differentiation, human iPS cells were passaged using gentle cell  
19 dissociation reagent (STEMCELL, catalog #07174) and replated at a density of 3.5\*10<sup>5</sup> cells/well on 12-well  
20 plates. Using STEMdiff<sup>TM</sup> Cardiomyocyte Differentiation and Maintenance kits (STEMCELL, catalog #05010  
21 & #05020), after cells reached 95% confluency, differentiation was initiated by replacing mTeSR with  
22 STEMdiff<sup>TM</sup> Cardiomyocyte Differentiation medium supplemented with Matrigel and STEMdiff<sup>TM</sup>  
23 Cardiomyocyte Differentiation Supplement A. Subsequently, cells were refed every two days, using  
24 STEMdiff<sup>TM</sup> Cardiomyocyte Differentiation Supplement B & C, respectively. At Day 8, the medium was  
25 changed to complete STEMdiff<sup>TM</sup> Cardiomyocyte Maintenance Medium, and it was changed every other day

for 7 days. Cells typically began beating spontaneously on approximately day 8 after differentiation. Cardiomyocytes were purified from day 10 of differentiation using lactate method(sodium L-lactate, Sigma-Aldrich, USA).

For the generation of neural progenitor cells (NPCs), embryonic body (EB) protocol using STEMdiff neural induction medium and SMADi (STEMdiff™ SMADi Neural Induction Kit, Catalog#05835) was implemented. Briefly, aggrewell™800 plates were prepared for experiments by pre-treatment of the wells with anti-adherence rinsing solution. Subsequently, each well was seeded with  $3 \times 10^6$  cells of single-cell suspension. Uniform EBs were observed in the aggrewell™800 plates on day 1, ~75% of the medium was replaced with fresh media every day for four days. EBs were harvested and replated at day 5 and medium was fully changed each day for six days. The percentage of cells induced to a neuronal fate was calculated on Day 8 based on the number of EBs with more than 50% neural rosettes divided by total number of EBs, and it was found to be ~90%. On Day 12 neural rosettes were selected and replated, and full medium changes were performed daily, using STEMdiff™ Neural Induction medium plus SMADi for another five days and the NPCs were passaged on Day 18. Neurons were generated from human iPS-NPCs using the STEMdiff™ Neuron Differentiation kit (STEMCELL, catalog #08500) and STEMdiff™ Neuron Maturation kit (STEMCELL, catalog #08510). Briefly, for neuronal differentiation we used a poly-L-ornithine/laminin coating and complete STEMdiff™ Neuron differentiation medium. Neuronal precursors were seeded at a density of  $3 \times 10^4$  cells/cm<sup>2</sup> and neurons were allowed to mature for at least one week in STEMdiff™ Neuron Maturation medium or Brainphys™ Neuronal medium (STEMCELL, catalog #05790) supplemented with Neurocult™ SM1 Neuronal supplement (STEMCELL, catalog #05711), N2 supplement-A (STEMCELL, catalog #07152), recombinant human brain derived neurotrophic factor, recombinant human glial-derived neurotrophic factor, dibutyryl cAMP, and ascorbic acid.

**Electrocardiography and transthoracic echocardiograms.** ECG recordings were obtained from conscious mice for at least 30 minutes, using the INDUS Rodent Surgical Monitoring system without anesthesia. Echocardiograms to measure ventricular size, wall thickness, and ejection fraction were performed

on mice using the Vevo 2700 VisualSonics System (Toronto, ON, Canada). Prior to echocardiography, mice were injected with the sedative midazolam (with 0.1 mg subcutaneous injection). Cardiac images were obtained using a 30-MHz linear array transducer. Images of the parasternal short and long axis were obtained at a frame rate of ~180-250 Hz. All image analysis was performed offline using the Vevo 2100 analysis software (v.1.5). Endocardial and epicardial borders were traced on the short axis view during diastole and systole. LV length was measured from endocardial and epicardial borders to the LV outflow tract in diastole and systole. The biplane area-length method was then used to calculate LV mass and ejection fraction. Diastolic function was measured using tissue Doppler imaging of the mitral annulus.

**Patch-clamp.**  $\text{Na}^+$  current measurements were conducted using the whole cell patch-clamp technique as previously described (9). For voltage clamp studies, command pulses were generated using an Axopatch 200B patch clamp amplifier (Molecular Devices, San Jose, CA) and currents were sampled at 20 KHz through an A/D converter (DigiData 1440, Molecular Devices, CA) and low pass filtered at 5 kHz. Electrode offset potentials were zero-adjusted before a Giga-seal was formed. Fast- and slow capacitance was compensated.  $\approx 85\%$  series resistance was also compensated, yielding a maximum voltage error of  $\sim 1\text{ mV}$ . To minimize the effects of  $\text{I}_{\text{Na}}$  run-down on the results of the experiments, we carefully monitored the time-dependent change of  $\text{I}_{\text{Na}}$ . Recordings were started after the current reached a steady state, normally within 5 to 8 minutes. To record  $\text{Na}^+$  currents from HEK293 cells, electrodes of 2-3 M $\Omega$  were filled with a pipette solution containing (in mmol/liter) NaF 10, CsF 110, CsCl 20, EGTA 10 and HEPES 10 (pH 7.35 with CsOH), and the bath solution contained NaCl 40, 103 NMDG, KCl 4.5,  $\text{CaCl}_2$  1.5,  $\text{MgCl}_2$  1, and HEPES 10 (pH 7.35 with CsOH). For recording from human iPS-CMs, the bath solution contained 50 NaCl, 110 CsCl, 1.8  $\text{CaCl}_2$ , 1  $\text{MgCl}_2$ , 10 HEPES, 10 glucose, 0.0001  $\text{CdCl}_2$  (pH 7.4 with CsOH). Patch pipettes were filled with 10 NaCl, 135 CsCl, 2  $\text{CaCl}_2$ , 3 MgATP, 2 TEA-Cl, 5 EGTA and 10 HEPES (pH 7.2 with CsOH). All experiments were performed at room temperature (20-22 °C). Current-voltage (I-V) relationships were generated by plotting the current density elicited by voltage steps from -80 mV to +50 mV, at 5 mV intervals, from holding potential of -120 mV. Cellular capacitance was measured, and  $\text{I}_{\text{Na}}$  was normalized to cellular capacitance.

1       **Measurement of Ca<sup>2+</sup>-transient using confocal microscopy.** Dissection of the SAN was performed in  
2 Tyrode solution (36°C) under the dissecting microscope. The SAN was delineated by the crista terminalis, the  
3 orifice of superior vena cava and the interatrial septum. Spontaneous beating Ca<sup>2+</sup> or field-stimulated steady-  
4 state Ca<sup>2+</sup> transients were measured in non-patched SAN cells or human iPS-CMs at ~35°C. These cells were  
5 loaded with Rhod-2 AM (AAT Bioquest, Inc, Catalog #21062) at room temperature for 30 minutes, followed by  
6 de-esterification in Tyrode's solution (containing 1.8 mM Ca<sup>2+</sup>) for 15 minutes. Line-scan confocal images were  
7 acquired at a sampling rate of 1.93 ms per line using a 63×, 1.3 NA oil immersion objective mounted on a Zeiss  
8 LSM 510 confocal microscope (Carl Zeiss MicroImaging GmbH). Steady-state Ca<sup>2+</sup> transients were achieved  
9 by a 30-second pacing at spontaneous beating for the SAN at 0.5 Hz for human iPS-CMs. SR Ca<sup>2+</sup> content was  
10 determined after steady-state stimulation at 1 Hz by measuring the amplitude of the Ca<sup>2+</sup> release induced by  
11 local delivery of 20 mM caffeine. All digital images were processed using IDL 8.0 (Research System Inc).

12       **Immunoprecipitation and immunoblotting.** Immunoprecipitation was carried out by incubating 4 µl of  
13 the acetyl-lysine antibody (Cell Signaling Technology, 9814) with 1 mg of tissue homogenate overnight,  
14 followed by adding 40 µl of protein A dynabeads (ThermoFisher) for 1 hour. After washing,  
15 immunoprecipitates were boiled in SDS-PAGE gel loading buffer, along with 500 µg of whole-cell lysates  
16 subjected to SDS-PAGE, transferred to nitrocellulose membrane and probed with a 1:500 dilution of the  
17 specified primary antibody and a 1:5000 dilution of peroxidase-conjugated secondary antibody.

18       Heart and cerebellar tissues were homogenized in RIPA buffer containing protease inhibitor cocktail  
19 (Roche). After quantification with BCA, equal amounts of proteins were loaded onto an SDS-PAGE gel,  
20 followed by standard immunoblotting. Chemiluminescent signal was developed using SuperSignal West Femto  
21 Maximum Sensitivity substrate (ThermoFisher, 34095), and blots were imaged using a GelDoc 2000 Chemi  
22 Doc system. Band densities were quantified using Image J (NIH).

23       **Antibodies** Primary antibodies used were against Nav1.5 (Alomone, 493-511), SERCA2a, custom designed  
24 anti-acetyl-K1479 Nav1.5 (YenZym Antibodies), Ndufs2 (Invitrogen, PA5-22364), Ndufs4 (ABclonal,  
25 A13519), p53 (ABclonal, A0263), Acetyl-p53 (Lys382) (Invitrogen, 710294), Anti-p53 (acetyl K120) (Abcam,

ab78316), cleaved caspase-3 (Cell Signaling Technology, Asp175), VGluT1(Sigma-Aldrich, ZRB2374) and VGAT (Sigma-Aldrich, AMAB91043).

**Live cell staining and immunostaining.** The HEK293 and iPS-CMs were plated on glass-bottom dishes. For live staining, the culture medium in the dish was exchanged with prewarmed (37°C) culture medium containing DCFDA (5mM) and TMRE (25nM), incubated for ~30 minutes, then counterstained with Hoechst 33342 in new medium. For immunostaining, HEK293, iPS-CM and iPS-N cells were fixed in 4% paraformaldehyde, blocked, and incubated in primary antibodies overnight. They were then probed with secondary antibody and counterstained with DAPI. Images were acquired using a Leica SP8 confocal microscope.

**Metabolic chamber measurements.** For analysis of whole-animal energy expenditure, animals were placed in the Oxymax CLAMS (Comprehensive Lab Animal Monitoring System, Columbus Instruments, Columbus, OH, USA) instruments. These cages have an open circuit system that directly measures various parameters over a 72-hour period, such as heat production, food intake, and movement (36). The Oxymax system has an open-circuit indirect calorimeter for lab animal research, allowing the measurement of oxygen consumption ( $\text{VO}_2$ ), respiratory exchange ratio (RER), and activity levels of mice.  $\text{VO}_2$  is a measure of the volume of oxygen used to convert energy substrates into ATP. The RER is calculated as the ratio of carbon dioxide production ( $\text{VCO}_2$ ) to oxygen consumption and can be used to estimate the fuel source for energy production based on the difference in the number of oxygen molecules required for the oxidation of glucose versus fatty acids. An RER of 0.7 indicates that fatty acids are the primary substrates for oxidative metabolism, whereas an RER of 1.0 indicates that carbohydrates are the primary energy substrates. Activity was calculated by summing the X-axis movement counts associated with horizontal movement<sup>35</sup>. All protocols were approved by the University of Iowa Animal Care and Use Committee (IACUC). Heat production was calculated using the equation derived from Lusk (~1928) to estimate aerobic respiration ( $\text{Heat} = 1.232 \cdot \text{VCO}_2 + 3.815 \cdot \text{VO}_2$ ).  $\text{VCO}_2$  is described as the rate of carbon dioxide produced by the mouse, and  $\text{VO}_2$  is described as the rate at which oxygen is consumed by the mouse.

1 **Metabolomics measurements.** All three groups of mice (WT,  $Ndufs4^{-/-}$ ,  $Ndufs4^{-/-}$ +NR; n=4 each group)  
2 were euthanized. The cerebellum/midbrain and heart were rapidly frozen in liquid nitrogen within one minute of  
3 removal from the mice.

4 **GC-MS method.** For metabolite extraction, the samples were extracted in ice cold 2:2:1  
5 methanol/acetonitrile/water which contained a mixture of 9 internal standards ( $d_4$ -Citric Acid,  $^{13}C_5$ -Glutamine,  
6  $^{13}C_5$ -Glutamic Acid,  $^{13}C_6$ -Lysine,  $^{13}C_5$ -Methionine,  $^{13}C_3$ -Serine,  $d_4$ -Succinic Acid,  $^{13}C_{11}$ -Tryptophan,  $d_8$ -Valine;  
7 Cambridge Isotope Laboratories) at a concentration of 1 ug/ml each. The ratio of extraction solvent to sample  
8 volume was 18:1. Tissue samples were lyophilized overnight prior to extraction. Tissues were homogenized  
9 using a ceramic bead mill homogenizer, after the addition of extraction buffer. The samples were then incubated  
10 at  $-20^{\circ}C$  for 1 hour followed by a 10-minute centrifugation at maximum speed. Supernatants were transferred  
11 to fresh tubes. Pooled quality control (QC) samples were prepared by adding an equal volume of each sample  
12 to a fresh 1.5 ml microcentrifuge tube. Processing blanks were utilized by adding extraction solvent to  
13 microcentrifuge tubes. Samples, pooled QCs, and processing blanks were evaporated using a speed-vac. The  
14 resulting dried extracts were derivatized using methoxyamine hydrochloride (MOX) and N,O-  
15 Bis(trimethylsilyl)trifluoroacetamide (TMS) [both purchased from Sigma]. Briefly, dried extracts were  
16 reconstituted in 30  $\mu L$  of 11.4 mg/ml MOC in anhydrous pyridine (VWR), vortexed for 10 min, and heated for  
17 1 hour at  $60^{\circ}C$ . Next, 20  $\mu L$  TMS was added to each sample, and samples were vortexed for 1 minute before  
18 heating for 30 minutes at  $60^{\circ}C$ . The derivatized samples, blanks and pooled QCs were then immediately  
19 analyzed using GC/MS.

20 GC chromatographic separation was conducted on a Thermo Trace 1300 GC with a TraceGold TG-5SilMS  
21 column (0.25  $\mu m$  film thickness; 0.25mm ID; 30 m length). The injection volume of 1  $\mu L$  was used for all  
22 samples, blanks, and QCs. The GC was operated in split mode with the following settings: 20:1 split ratio; split  
23 flow: 24  $\mu L$ /min, purge flow: 5 mL/min, Carrier mode: Constant Flow, Carrier flow rate: 1.2 mL/min). The GC  
24 inlet temperature was  $250^{\circ}C$ . The GC oven temperature gradient was as follows:  $80^{\circ}C$  for 3 minutes, ramped at  
25  $20^{\circ}C$ /minute to a maximum temperature of  $280^{\circ}C$ , which was held for 8 minutes. The injection syringe was

1 washed 3 times with pyridine between each sample. Metabolites were detected using a Thermo ISQ single  
2 quadrupole mass spectrometer. The data was acquired from 3.90 to 21.00 minutes in EI mode (70eV) by single  
3 ion monitoring (SIM). Metabolite profiling data was analyzed using Tracefinder 4.1 utilizing standard verified  
4 peaks and retention times.

5 We used TraceFinder 4.1 to identify metabolites in extracted samples, blank, and QCs. We do this by  
6 comparing sample metabolite peaks against an in-house library of standards. The standard library was prepared  
7 by processing and analyzing authentic standards via the method described above. We created a database of  
8 retention times and three fragment ions for each metabolite standard: a target peak/ion and two confirming  
9 peaks/ions. When running biological samples, metabolites are identified that not only match with the known  
10 retention times of the authentic standard, but also with its target and confirming peaks. Tracefinder was also  
11 used for GC-MS peak integration to obtain peak areas for each metabolite. After TraceFinder analysis,  
12 instrument drift over time is corrected for using local regression analysis as described by Li et al <sup>36</sup>. Pooled QC  
13 samples which were run in duplicate at the beginning and end of the GC-MS run were used for this purpose.  
14 The data are then normalized to an internal standard to control for extraction, derivatization, and/or loading  
15 effects.

16 **Sample preparation for LC-MS.** For metabolite extraction, samples were extracted in ice cold 2:2:1  
17 methanol/acetonitrile/water which contained a mixture of 9 internal standards (d4-Citric Acid, 13C5-Glutamine,  
18 13C5-Glutamic Acid, 13C6-Lysine, 13C5-Methionine, 13C3-Serine, d4-Succinic Acid, 13C11-Tryptophan, d8-  
19 Valine; Cambridge Isotope Laboratories) at a concentration of 1 µg/ml each. The ratio of extraction solvent to  
20 sample volume was 18:1. Tissue samples were lyophilized overnight prior to extraction. Tissues were  
21 homogenized using a ceramic bead mill homogenizer, after the addition of extraction buffer. Samples were then  
22 incubated at -20°C for 1 hour followed by a 10 min centrifugation at maximum speed. 400ul of supernatants  
23 were transferred to fresh tubes. Pooled quality control (QC) samples were prepared by adding an equal volume  
24 of each sample to a fresh 1.5 ml microcentrifuge tube. Processing blanks were utilized by adding extraction  
25 solvent to microcentrifuge tubes. Samples, pooled QCs, and processing blanks were evaporated using a speed-

vac. The resulting dried extracts were reconstituted in 40  $\mu$ L of acetonitrile/ water (1:1, V/V), vortexed and samples, blanks and pooled QCs were then analyzed using LC-MS.

**LC-MS Analysis.** 2  $\mu$ L of metabolite extracts were separated using a Millipore SeQuant ZIC-pHILIC (2.1 X 150 mm, 5  $\mu$ m particle size) column with a ZIC-pHILIC guard column (20 x 2.1 mm) attached to a Thermo Vanquish Flex UHPLC. Mobile phase comprised Buffer A – 20 mM (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub>, 0.1% NH<sub>4</sub>OH and Buffer B: acetonitrile. The chromatographic gradient was run at a flow rate of 0.150 mL/min as follows: 0–21 min-linear gradient from 80 to 20% Buffer B; 20–20.5 min-linear gradient from 20 to 80% Buffer B; and 20.5–28 min-hold at 80% Buffer B<sup>37</sup>. Data was acquired using a Thermo Q Exactive mass spectrometer operated in full-scan, polarity-switching mode with a spray voltage set to 3.0 kV, the heated capillary held at 275 °C, and the HESI probe held at 350 °C. The sheath gas flow was set to 40 units, the auxiliary gas flow was set to 15 units, and the sweep gas flow was set to 1 unit. MS data acquisition was performed in a range of m/z 70–1,000, with the resolution set at 70,000, the AGC target at 10<sup>6</sup>, and the maximum injection time at 200 ms. Acquired LC-MS data were processed by Thermo Scientific TraceFinder 4.1 software, and metabolites were identified based on the University of Iowa Metabolomics Core facility in-house, physical standard-generated library. NOREVA was used for signal drift correction<sup>36</sup>. Data per sample were then normalized to an internal standard (13C5-Methionine) to control for extraction, derivatization, and/or loading sample effects.

**Statistics.** All analyses and calculations were performed using GraphPad Prism (version 8.0; GraphPad Software, Inc., CA, USA). The results are expressed as the mean  $\pm$  standard error of the mean or proportion. Differences between groups were evaluated using Student's t test, Kruskal Wallis test and analysis of variance (ANOVA) with Tukey's test for comparison between two and multiple groups, respectively. Survival curves were drawn using the Kaplan-Meier method. To compare survival curves between groups, the log-rank test was applied. A p-value less than 0.05 was considered statistically significant.

**Data availability:** The datasets generated and/or analyzed during the current study are included in this published article.

**Study approval.** All animal experiments were approved by the Institutional Animal Care and Use Committee (IACUC) at the University of Iowa.

**Author contributions:** JYY, DN, DFD performed experiments, data analysis and manuscript writing; YC, BC performed experiments and assisted in data analysis; MH performed neuropathological analysis, KI, LSS, BL, EDA and CB supervised the study, provided reagents and provided critical revision and editing of the manuscript; DFD developed the concept and design of the study. The order of co-first authorship is assigned by alphabetical order of the authors' name.

**Acknowledgments:** We thank the Fraternal Order of Eagles Diabetes Research Center Metabolomics Core Facility in the Carver College of Medicine at the University of Iowa for assistance in the measurement of metabolites. This research is supported by National Institutes of Health (grant reference number K08 HL145138 to DFD, and R01 HL147545 to KI, CB, BL).

**Fig. 6. Deletion of Ndufs4 Decreased  $Na_v1.5$  current in human iPS-derived cardiomyocytes.** (a) Representative immunoblots and (b) immunofluorescence images of WT and Ndufs4 KO human iPS-CMs immunolabeled for Ndufs4. (c) Live staining of control and Ndufs4 KO human iPS-CMs, with or without NR pretreatment, with TMRE (red) and DCFDA (green). (d) Quantitation of fluorescence in panel c (Data representative of three independent experiments). (e-f) Amplitude, decay rate (T50) and calcium transient in control and Ndufs4 KO human iPS-CMs with or without NR treatment, red line representing the slope

**Fig. 7. Human iPS-Neurons with Ndufs4KO are more susceptible to glutamate-induced apoptosis, mediated through acetylation of p53.** (a-b) Characterization of human iPS-Ns by immunofluorescence for pan-neuronal marker  $\beta$ -Tubulin (Tu-20), vGAT (vesicular GABA transporter) or vGluT1 (vesicular glutamate transporter). (c) Morphology of mature human iPS-Neurons. (d-e) Representative fluorescence images of iPS-neurons treated with glutamate (30  $\mu$ M), NR (1mM), and EX527 (10  $\mu$ M). (f) Quantitation of relative fluorescence intensity of indicated groups in d-e (log-transformed for data normalization). (g) Representative western blot of K120-p53 in mouse cerebellum/midbrain from specified treatment groups and quantification (Data are representative of three independent experiments) (\*  $p < 0.001$ ).

**Fig. 8. Schematic illustration of the molecular mechanism of cardio-encephalomyopathy in *Ndufs4* KO mice and hiPSCs.**
