Abstract

20   The SARS-CoV-2 Omicron variant exhibits striking immune evasion and is spreading
21   globally at an unprecedented speed. Understanding the underlying structural basis of the high
22   transmissibility and greatly enhanced immune evasion of Omicron is of high importance. Here
23   through cryo-EM analysis, we present both the closed and open states of the Omicron spike,
24   which appear more compact than the counterparts of the G614 strain, potentially related to the
25   Omicron substitution induced enhanced protomer-protomer and S1-S2 interactions. The closed
26   state showing dominant population may indicate a conformational masking mechanism of
27   immune evasion for Omicron spike. Moreover, we capture two states for the Omicron S/ACE2
28   complex with S binding one or two ACE2s, revealing that the substitutions on the Omicron
29   RBM result in new salt bridges/H-bonds and more favorable electrostatic surface properties,
30   together strengthened interaction with ACE2, in line with the higher ACE2 affinity of the
31   Omicron relative to the G614 strain. Furthermore, we determine cryo-EM structures of the
32   Omicron S/S3H3 Fab, an antibody able to cross-neutralize major variants of concern including
33   Omicron, elucidating the structural basis for S3H3-mediated broad-spectrum neutralization.
34   Our findings shed new lights on the high transmissibility and immune evasion of the Omicron
35   variant and may also inform design of broadly effective vaccines against emerging variants.

36

Introduction

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has undergone considerable evolution since its initial discovery in December 2019, leading to the emergence of a number of variants of concerns (VOCs) including Alpha (B.1.1.7)[1-5], Beta (B.1.351)[4-8], Gamma (P1)[9], and Delta (B.1.617.2)[10,11]. These variants that harbor multiple mutations on their spike (S) protein show enhanced transmissibility and resistance to antibody neutralization[11]. Recently, a new variant, named Omicron (B.1.1.529), was first reported in South Africa in November 2021 and classified as the fifth VOC by the World Health Organization (WHO) on 26 November 2021. Omicron exhibits a high transmission rate (R0>3)[12,13], and, as of 22 December 2021, it has spread into 110 countries[14] .

Omicron bears 37 mutations in its S protein relative to the original SARS-CoV-2 strain[15,16]. As the consequence, Omicron has been observed to extensively escape neutralization by previously developed neutralizing monoclonal antibodies (MAbs) or sera from vaccines or convalescent individuals[15,17-22]. Among all of the Omicron S mutations, 15 are present in the receptor-binding domain (RBD) that mediates the virus binding to its host-cell receptor— angiotensin-converting enzyme 2 (ACE2) and is also a major target for neutralizing antibodies[23-27]. In particular, 9 mutations are located within the receptor-binding motif (RBM) interacting directly with ACE2. However, Omicron still uses ACE2 as its entry receptor[22]. Moreover, the Omicron S appears to have an increased binding affinity to human ACE2 relative to the WT S[15,16,28].

The high transmissibility and greatly enhanced resistance to antibody neutralization observed for Omicron makes this VOC particularly threatening. Therefore, further understanding of the nature of Omicron is of significant importance and may help in developing countermeasures against this VOC. The present study aimed to address from a structural aspect how Omicron binds the ACE2 receptor and how it recognizes or evades neutralizing antibodies raised against the original virus. We captured two cryo-EM structures of the Omicron S trimer in the closed and open state at 3.08- and 3.21-Å-resolution, respectively, revealing the Omicron spike is structurally more compact compared to the counterparts of the G614 strain. This could be related to the unique Omicron substitutions in SD1 and S2 regions. We also obtained two states of the Omicron S/ACE2 complex with S binding one or two ACE2s, respectively, suggesting that the substitutions on the RBM of Omicron result in formation of new salt bridges and H-bonds, as well as more complementary electrostatic surface properties. Moreover, we determined cryo-EM structures of the Omicron S in complex with the Fab of S3H3[29], an

70 antibody able to cross-neutralize major VOCs including Omicron, thus allowing elucidation of

71 the structural basis for S3H3-mediated broad-spectrum neutralization.

72 **Results**

73 **Closed and open state structures of the Omicron S trimer**

74 To inspect the impact of the Omicron intense substitutions on the spike conformation, we

75 prepared a prefusion-stabilized trimeric S protein of SARS-CoV-2 Omicron variant (Fig. S1)

76 and subsequently determined its cryo-EM structures. Two cryo-EM maps, including an all

77 RBD down conformation (termed Omicron S-close) and a one RBD-up open conformation

78 (termed Omicron S-open), were obtained at 3.08- and 3.21-Å-resolution, respectively (Fig. 1A-

79 B and Fig. S2A-C, Table S1). We then built an atomic model for each of the two structures

80 (Fig. 1C, S2D). For the Omicron S-close state, the three protomers are well resolved and they

81 display similar conformation with their RBDs in the down position (Fig. S2C and Fig. 1E).

82 Strikingly, the Omicron S-close appears more twisted/compact in the RBDs relative to the

83 G614 S-close structure (Fig. 1F)[30]. Also, in the Omicron S-open state, structural comparison

84 showed that the RBDs are slightly more twisted/compact than that of the G614 S-open[30] (Fig.

85 1G). There is no linoleic acid (termed LA) in the Omicron S-open and S-close maps, as in our

86 recent Delta, Kappa, and Beta S structures obtained in the same construction and purification

87 condition[31,32]. LA binding has been detected in the tightly closed WT S trimer structures[33-36],

88 and been suggested to lead to more compacted RBDs[33]. Collectively, the Omicron S trimer is

89 more compact than that of G614, and this is not caused by LA binding. Moreover, in the

90 Omicron S-open structure, the down RBD-3 is relative dynamic and less well resolved than

91 RBD-2 (Fig. 1B). Our further 3D variability analysis (3DVA)[37] on the Omicron S trimer dataset

92 revealed an intrinsic rising up motion of RBD-1, which could alter the original RBD-1/-3

93 contact and destabilize RBD-3, making it extremely dynamic and may transiently rise up (Fig

94 1H, Movie S1).

95 Noteworthy, the population distribution of the Omicron S-close and S-open is about 61%

96 and 39% (Fig. 1D), respectively, displaying a considerable population distribution shift to the

97 closed state than that of the Kappa and Beta variants S trimer (both around 50%-50% open-

98 transition ratio) or that of the Delta S (75.3%-24.7% open-transition ratio) from our recent

99 studiues[31,32]. Taken together, the Omicron S trimer appears more prone to the closed state and

100 potentially stabilized relative to the counterparts of the G614, Kappa, Beta, and Delta variants.

101 To investigate the underlying molecular basis of this extra stability, we inspected the protomer

102   interaction interface of Omicron S-close (Table S2, S3) and found three sets of new hydrogen

103   bond (H-bond) and salt bridge interactions induced by the unique Omicron substitutions

104   beyond the NTD/RBD regions (Fig. 1I). Specifically, the T547K from the SD1 of protomer 1

105   forms a new H-bond with the N978 from S2 of protomer 3, which could enhance the S1-S2

106   subunits interaction between the two protomers; the N856K and N764K from protomer 1 can

107   form H-bonds with T572 and Q314 from protomer 2, respectively. We also observed multiple

108   new H-bonds and salt bridges formed between the N317/R319 of protomer 1 and the D737 of

109   protomer 3. These extra interactions mainly induced by Omicron substitutions in SD1 and S2

110   contribute greatly to the linkage/allosteric network between neighboring protomers and

111   between the S1 and S2 subunits, markedly stabilizing the Omicron S trimer and inhibiting its

112   transformation towards the fusion-prone open state and subsequent shielding of S1.

113   **Structural basis of enhanced S-ACE2 interaction for the Omicron variant**

114   Compared with the WT strain, the Omicron variant bears 15 mutations in the RBD region,

115   9 of which are located in RBM[15]. We assessed whether these mutations affect the human ACE2

116   receptor-binding ability of the Omicron S trimer by performing biolayer interferometry (BLI)

117   assay. The S trimers of the G614 and Delta variant were also analyzed for comparison purpose.

118   We found that the ACE2-binding affinity of the Omicron S trimer ($K_D = 80$ nM) is comparable

119   to that of the Delta S ($K_D = 88$ nM) but is about 3 folds higher than that of the G614 S ($K_D =$

120   237 nM) (Fig. 2A), in consistence with the data from other recent preprints[15,16,28].

121   Next, we carried out cryo-EM study on the Omicron S trimer in complex with human

122   ACE2 peptidase domain (PD) (Fig. S3). We obtained two cryo-EM maps (Fig. 2B), including

123   a conformation with one RBD up and engaged with an ACE2 (termed Omicron S-ACE2-C1)

124   and another one containing two "up" RBDs (RBD-1 and RBD-2) bound with ACE2 (termed

125   Omicron S-ACE2-C2), at 3.69- and 3.66-Å-resolution, respectively (Fig. S4A-B, and Table

126   S1). In the S-ACE2-C2 map, density of RBD-2-associated ACE2 appears weaker than that of

127   the stably associated ACE2 on RBD-1. We then built an atomic model for each of the two

128   structures (Fig. S4C). The population distribution between Omicron S-ACE2-C1 and -C2 is

129   about 43.9% versus 56.1% (Fig. 2C), displaying an obvious higher one-RBD-up C1 population

130   than that of the Beta/Kappa/Delta variants (C1 population ranges from 8.3% to 14.1%)

131   observed in our recent studies[31,32]. These three variants also showed a C3 state with all-three-

132   up RBDs associated with ACE2 (27.7% to 46.6% populated)[31,32], not detected here in the

133   Omicron variant, in line with recent preprint reports[16,28,38]. Taken together, the Omicron S

134   trimer exhibits less ability to transform to the more RBD-up C2/C3 states as compared to that

135   of the Beta, Kappa, and Delta VOCs.

136   To further understand the structural details of the RBD-ACE2 interaction interface, we

137   focus-refined the stably associated Omicron RBD-1-ACE2 region to 3.67-Å-resolution (Fig.

138   2D and Fig. S4A). Inspection of this map revealed that many of the substitutions in RBM,

139   including Q493R, G496S, Q498R, S477N, and Y505H, exhibit new interactions with ACE2

140   receptor compared with the interaction interface of the WT RBD-ACE2 (PDB: 6M0J)[26].

141   Specifically, Q493R with ACE2 E35 and Q498R with ACE2 D38 form three new salt bridges;

142   G496S and Y505H both with ACE2 K353, Q498R with ACE2 Q42, and S477N with ACE2

143   Q19 form new H-bonds (Fig. 2D-E, Table. S4), generally in line with recent studies[16,28,38-41].

144   Moreover, we observed an extra H-bound between T500 and ACE2 D355 (Fig. 2E). Our

145   previous research defined that Y505A obviously decreased ACE2 binding affinity[36], so Y505H

146   mutation in Omicron may maintain or even enhance ACE2 binding. In the meanwhile, the

147   K417N substitution, occurred in Omicron as well as in Beta and Delta variants, is known to

148   markedly reduce ACE2 binding through abolishing multiple salt bridges/H-bonds with ACE2

149   D30[26,42,43]. Together, these newly formed RBM-ACE2 interactions may compensate the loss

150   of some original RBM-ACE2 interactions due to the residue changes introduced into the

151   Omicron RBM.

152   Further inspection of the surface property showed that the substitutions in RBM,

153   especially Q493R, G496S, Q498R, and Y505H, render the substituted site within the ACE2

154   interaction footprint more positively charged, which could strengthen the RBM interaction with

155   the overall negatively charged ACE2 in the interaction interface (Fig. 2G-H). Corroborating

156   this, the Omicron RBD-ACE2 interaction area (920.2 Å^2) is enlarged compared to that of the

157   WT (843.3 Å^2), while it is comparable to that of the Delta RBD-ACE2 (928.4 Å^2)[32] (Fig. 2F).

158   This is also in agreement with our BLI data showing that the ACE2-binding affinity of the

159   Omicron S is similar to that of the Delta S but is higher than that of the G614 S (Fig. 2A).

160 **Sensitivity of Omicron to select neutralizing antibodies**

161   We have generated a number of MAbs that potently neutralize the original SARS-CoV-2

162   strain in previous studies[29,44]. Five of these MAbs, including 2H2[44], 3C1[44], 8D3[44], S5D2[29], and

163   S3H3[29], were selected and tested in parallel for neutralization of the wild-type (WT, Wuhan-

164   Hu-1 strain), Delta, or Omicron pseudoviruses. The neutralization data were shown in Fig. 3A-

165   B. It was found that the IC50 values of MAbs 3C1, 2H2, 8D3, and S3H3 against Delta were

166 comparable (less than 2.5-fold variation) to the corresponding ones against WT, whereas S5D2

167 was still neutralizing to Delta (IC50 = 734.6 ng/mL) but was about 90-fold less potent. In

168 Omicron neutralization tests, three MAbs, 3C1, 8D3, and S5D2, lost neutralization activity

169 (IC50 > 10 µg/mL). However, 2H2 and S3H3 remained highly effective against Omicron with

170 IC50s being 30.4 and 53.3 ng/mL, respectively, despite that a 3.3-fold increase (relative to the

171 WT) in IC50 value was observed for 2H2. These data demonstrate that 2H2 and S3H3 are two

172 potent neutralizing MAbs against Omicron and also show that Omicron can more extensively

173 escape antibody neutralization than Delta.

174   We then compared the binding ability of the five MAbs to the WT, Delta, and Omicron S

175 proteins by ELISA. As shown in Fig. 3C, for MAb S5D2, its binding to the Delta and to the

176 Omicron S was nearly abolished; for MAbs 3C1 and 8D3, their reactivity profile with the Delta

177 S closely resembled that towards the WT S but their binding to the Omicron S reduced

178 significantly; for MAb 2H2, its binding curve to the Omicron S was similar to those towards

179 the WT and Delta S despite the binding efficiency to the Omicron S was slightly lower;

180 meanwhile, MAb S3H3 produced nearly identical binding curves to the three S proteins.

181 Overall, the antigen-binding ability of the MAbs was in good agreement with their

182 neutralization potency towards specific variant pseudovirus (Fig. 3A-C).

183   Collectively, the above results demonstrate that Omicron remains sensitive to binding and

184 neutralization by MAbs 2H2 and S3H3 whereas it displays resistance to 3C1, 8D3, and S5D2.

Structural basis of Omicron neutralization by a broadly neutralizing antibody S3H3

186   MAb S3H3 is a unique neutralizing antibody that binds the SD1 region of the WT S[29]. To

187 understand the structural basis of Omicron neutralization by S3H3, we carried out cryo-EM

188 study and obtained two structures of the SARS-CoV-2 Omicron S trimer in complex with S3H3

189 Fab in distinct conformational states (Fig. S5A). Both structures showed two engaged Fab

190 densities on the SD1 region of protomer 2 and protomer 3, but with the RBD-1 in the up (termed

191 Omicron S-open-S3H3) or down (termed Omicron S-close-S3H3) conformations (Fig. 4A-B).

192 The two maps were resolved to the resolution of 3.48 Å and 3.64 Å, respectively (Fig. S5C-D

193 and Table S1). We then built an atomic model for each of the two structures（Fig.

194 S5B）. Compared with the free Omicron S-open, the S trimer in the S-open-S3H3 structure

195 exhibited a slight twist and the RBD-1 displayed a 9.1° downward rotation (Fig. 4C), making

196 the S trimer seemingly less "open" as a whole. Meanwhile, the SD1 showed a slight downward

197 rotation (Fig. 4C).

198   To examine the interaction interface between the S3H3 Fab and the Omicron SD1, we

199   further focused refined the SD1-S3H3 Fab region and obtained a map at 3.61-Å-resolution,

200   with most of the sidechain densities well resolved (Fig. 4D). Our structural analysis suggested

201   that the heavy chain of S3H3 Fab contributes more to the interactions with SD1 than the light

202   chain does, i.e., all the three heavy-chain CDRs of S3H3 and its CDRL1 and CDRL3 interact

203   with T323-E324 and the three loops (loop$^{532-537}$, loop$^{554-556}$, and loop$^{581-584}$) of SD1 (Fig. 4E-F

204   and Table. S7). Specifically, the S32 of CDRL1 forms H-bonds with the S555 and I584 of SD1,

205   respectively, the D102 of CDRH3 forms a H-bond with the T581 from loop$^{581-584}$, and the D55

206   of CDRH2 forms a salt bridge with the K537 from loop$^{532-537}$ (Fig. 4G and Table. S6), thus

207   constituting an intense interaction network between S3H3 Fab and SD1. A single mutation,

208   T547K, is present in the SD1 region of Omicron, however, this mutation locates outside the

209   footprint of S3H3 (Fig. 4F), thus will not affect the interaction between S3H3 and Omicron S.

210   Collectively, S3H3 binds the extremely conserved SD1 region, therefore retains binding and

211   neutralizing activity towards major VOCs including Omicron.

Discussion

213   The SARS-CoV-2 Omicron variant has replaced the Delta variant and is now the

214   predominant circulating VOC in many countries[14]. With 37 mutations in its spike, this variant

215   shows striking immune evasion while it also displays increased binding affinity with human

216   ACE2 relative to the WT strain[15,16,28]. Recent reports also showed that the Omicron S exhibits

217   reduced furin cleavage and less S1 shedding[45,46]. It is essential to understand how the mutations

218   present in the Omicron S contribute to the higher transmissibility and immune escape observed

219   for this threatening variant. In this study, we performed cryo-EM study and biochemical

220   analysis on the Omicron S trimer and its complex with ACE2 receptor or a broadly neutralizing

221   antibody S3H3. We captured both the closed and the open states of the Omicron S trimer (Fig.

222   1A-B). In contrast to the S trimer of Delta/Beta/Kappa variants[31,32], the Omicron S-close and

223   S-open structures appear more twisted/compact than their counterpart of the G614 strain (Fig.

224   1F-G). This could be related to the unique Omicron substitution (T547K, N856K, and N764K

225   in SD1 and S2)–induced enhanced interactions between neighboring protomers and between

226   S1 and S2 subunits (Fig. 1I), which may hinder its spike transformation towards the fusion-

227   prone open state and shielding of S1.

228   Noteworthy, our cryo-EM analysis revealed the dominantly populated (61%)

229   conformation for the Omicron S trimer is in the closed state with all the RBDs buried, resulting

230   in conformational masking preventing antibody binding and neutralization at sites of receptor

231 binding, similar to that described for HIV-1 envelope[47,48]. This Omicron conformational

232 masking mechanism of neutralization escape could affect all antibodies that bind to the up

233 RBDs (such as class 1, 2, and 4 RBD antibodies[49]). While for Delta S trimer, our recent work

234 showed the open-transition ratio is 75.3%-24.7%, indicating the conformational masking

235 mechanism may be less effective for the Delta variant[32,36]. This could contribute greatly to the

236 striking immune evasion of the Omicron variant[15,17-22].

237 We then captured two states for the Omicron S/ACE2 complex with S binding one or two

238 ACE2s under our experimental conditions (Fig. 2B-C). However, unlike the Delta S which

239 tends to bind three ACE2 in majority[32], Omicron binds up to two ACE2s. Further focus-refined

240 RBD-1/ACE2 structure demonstrated that the substitutions on the RBM of Omicron (especially

241 Q493R, G496S, Q498R, S477N, and Y505H) result in formation of new salt bridges and H-

242 bonds, as well as more complementary electrostatic surface properties (Fig. 2E-H), which

243 together may compensate abolished original RBM-ACE2 interactions[26,42,43], leading to

244 enhanced interactions with ACE2 and potentially enhanced transmissibility of the Omicron

245 variant.

246 SARS-CoV-2 variants gain series of mutations in their S proteins, including RBD and

247 NTD. As a consequence, VOCs significantly impact the potency of neutralizing antibodies

248 originally developed against WT strains[50,51]. Omicron contains specific alterations that have

249 previously been shown to impact vaccine resistance and also some newly introduced mutations.

250 It is thus important to determine whether antibodies capable of neutralizing Omicron exist and

251 if yes where they target. In the present study, we screened a panel of five previously isolated

252 and characterized neutralizing MAbs[44] for their potency against Omicron and Delta variants.

253 Our results show that 2H2 and S3H3 retain potent neutralization towards Omicron and Delta

254 (Fig. 3). Further structural study on the Omicron S-S3H3 Fab complex revealed a unique

255 binding epitope of S3H3 within the SD1 region which links the S1 and S2 domains (Fig. 4A-

256 E). S3H3 binding to S trimer may function as a "lock" to block the releasing of S1 from S2,

257 resulting in inhibition of virus entry. The SD1 region targeted by S3H3 is extremely conserved

258 among SARS-CoV-2 strains, with only one mutation T547K (which is away from the S3H3

259 binding footprint) present in Omicron (Fig. 4F), thus explaining the cross-neutralization ability

260 of S3H3 towards Omicron, Delta, and other variants[29]. These findings also suggest a possibility

261 to design SD1-based broad-spectrum SARS-CoV-2 vaccines.

262 In summary, the present study reveals that the Omicron spike is structurally more compact

263 compared to the counterparts of other VOCs and has the likelihood to associate with fewer

264   ACE2. The compact S-close state with dominant population may indicate a conformational

265   masking mechanism of immune evasion for Omicron spike. However, the Omicron spike still

266   maintains strong affinity to ACE2 due to an increased RBM-ACE2 interaction network

267   contributed by new H-bonds/salt bridges and more favorable surface properties, thus providing

268   a possible explanation to the high transmissibility of Omicron. In addition, our work shows

269   that Omicron is able to escape majority of the RBD-directed MAbs owing to a relatively large

270   number of residue changes in RBD and conformational masking, however, this variant remains

271   sensitive to the SD1-targeting neutralizing MAb S3H3. Our findings provide structural insights

272   into how Omicron maintains high transmissibility while greatly evades immunity, and may

273   also inform design of broadly effective vaccines against emerging variants.

274

Method

Expression and purification of recombinant proteins

To express SARS-CoV-2 Omicron variant S glycoprotein ectodomain, the mammalian codon-optimized gene coding SARS-CoV-2 (hCoV-19 Botswana R42B90_BHP_000842207 2021, GISAID ID: EPI_ISL_6752027) S glycoprotein ectodomain (residues M1-Q1208) with proline substitutions at K986 and V987, a "GSAS" substitution at the furin cleavage site (R682–R685) was cloned into vector pcDNA 3.1+. A C-terminal T4 fibritin trimerization motif, a TEV protease cleavage site, a FLAG tag and a His tag were cloned downstream of the S glycoprotein ectodomain (Fig. S1A). The constructs of prefusion-stabilized S proteins of SARS-CoV-2 G614 and Delta (B.1.617.2) variants were prepared as previously reported[32]. A gene encoding human ACE2 PD domain (Q18-D615) with an N-terminal interleukin-10 (IL-10) signal peptide and a C-terminal His tag was cloned into vector pcDNA 3.4[36]. The recombinant proteins were prepared as the published protocol[36]. Briefly, the constructs were transiently transfected into HEK293F cells using polyethylenimine (PEI). Three days after transfection, the supernatants were harvested by centrifugation, and then passed through 0.45 µm filter membrane. The clarified supernatants were added with 20 mM Tris-HCl pH 7.5, 200 mM NaCl, 20 mM imidazole, 4 mM $MgCl_2$, and incubated with Ni-NTA resin at 4°C for 1 hour. The Ni-NTA resin was recovered and washed with 20 mM Tris-HCl pH 7.5, 200 mM NaCl, 20 mM imidazole. The protein was eluted by 20 mM Tris-HCl pH 7.5, 200 mM NaCl, 250 mM imidazole.

Bio-layer interferometry (BLI) assay

Before BLI assay, Ni-NTA purified recombinant S trimer proteins of the G614, Delta and Omicron SARS-CoV-2 variants were further purified by gel filtration chromatography using a Superose 6 increase 10/300 GL column (GE Healthcare) pre-equilibrated with PBS. Then, the S trimer proteins were biotinylated using the EZ-Link™ Sulfo-NHS-LC-LC-Biotin kit (Thermo Fisher) and then purified by Zeba™ spin desalting columns (Thermo Fisher).

Binding affinities of S trimers to ACE2 were determined by BLI analysis on an Octet Red96 instrument (Pall FortéBio, USA). Briefly, biotinylated S trimer proteins were immobilized onto streptavidin (SA) biosensors (Pall FortéBio). After washing with kinetic buffer (0.01 M PBS with 0.02% Tween 20 and 0.1% bovine serum albumin), these sensors were incubated with 3-fold serial dilutions of ACE2 monomer protein for 500 s. Subsequently, the biosensors were allowed to dissociate in kinetic buffer for 500 s. The data were analyzed

307   using the Octet Data Analysis 11.0 software to calculate affinity constants.

308   **Neutralization**

309   Luciferase (Luc)-expressing pseudoviruses bearing SARS-CoV-2 S proteins were

310   constructed based on the HIV-1 backbone. Briefly, HEK 293T cells in 10-cm dish were co-

311   transfected using PEI (polysciences) with 10 μg of Pcmv-Dr8.91 packaging plasmid, 10 μg of

312   recombinant Plvx-IRES-ZsGreen1 plasmid containing luciferase reporter gene, and 2 μg of

313   recombinant Pvax1 plasmids encoding SARS-CoV-2 S proteins. The cells were incubated with

314   the transfection mixture for 6 h, and then 5 mL of fresh DMEM medium with 10% FBS was

315   added to each dish. After incubation overnight, the media in the dishes was replaced with fresh

316   DMEM medium (10% FBS). At 48 h post-transfection, the culture supernatant was harvested

317   and frozen at -80 °C before use.

318   All MAbs were 4-fold serially diluted and tested by pseudovirus neutralization assay with

319   human ACE2-overexpressing HEK 293T cells (293T-Hace2) following our previous

320   protocol[44]. Two days after pseudovirus infection, luciferase activity was measured. Data were

321   analyzed by non-linear regression using GraphPad Prism 8 to calculate half inhibitory

322   concentration (IC50).

323   **ELISA**

324   To test binding activities of recombinant Omicron S protein with our previously

325   developed anti-SARS-CoV-2 MAbs[29,44], recombinant S trimer proteins from WT[44], Delta, or

326   Omicron SARS-CoV-2 strains were 2-fold serially diluted and coated onto ELISA plates at

327   37 °C for 2 h. The plates were blocked with 5% milk in PBS-Tween 20 (PBST) at 37 °C for 1

328   h. After washing with PBST, the plates were incubated with 50 ng/well of each of the anti-

329   SARS-CoV-2 MAbs[29,44] at 37 °C for 2 h, followed by horseradish peroxidase (HRP)-

330   conjugated anti-mouse IgG (Sigma, 1/5,000 dilution) at 37 °C for 1 h. After washing and color

331   development, absorbance was measured at 450 nm. ELISA data were analyzed by non-linear

332   regression using GraphPad Prism 8.

333   **Omicron S trimer/S3H3 Fab complex formation.**

334   The Omicron variant S trimer/S3H3 Fab complex was prepared following our previously

335   reported protocol[29]. Briefly, purified S3H3 IgG was incubated with papain (300:1 W/W) in

336   PBS buffer (in the presence of 20 mM L-cysteine and 1 mM EDTA) for 3 h at 37°C. The

337   reaction was quenched by 20 mM iodoacetamide. Fab was purified by running over a HiTrap

338   DEAE FF column (GE Healthcare) pre-equilibrated with PBS. Omicron S protein was

339   incubated with S3H3 Fab in a 1:6 molar ratio on ice for 1 h. The Omicron S-S3H3 Fab complex

340   was purified by size-exclusion chromatography using Superose 6 increase 10/300 GL column

341   (GE Healthcare) in 20 mM Tris-HCl pH 7.5, 200 mM NaCl, 4% glycerol. The complex peak

342   fractions were concentrated and assessed by SDS-PAGE.

Cryo-EM sample preparation

344   To prepare the cryo-EM sample of the Omicron S trimer, a 2.2 µl aliquot of the sample

345   was applied on a plasma-cleaned holey carbon grid (R 1.2/1.3, Cu, 200 mesh; Quantifoil). The

346   grid was blotted with Vitrobot Mark IV (Thermo Fisher Scientific) at 100% humidity and 8 °C,

347   and then plunged into liquid ethane cooled by liquid nitrogen. To prepare the cryo-EM sample

348   of the Omicron S-ACE2 complex, purified Omicron S trimer was incubated with ACE2 in a

349   1:4 molar ratio on ice for 20 min and then vitrified using the same condition. The purified

350   Omicron S-S3H3 complex was vitrified using the same procedure as for the Omicron S sample.

Cryo-EM data collection

352   Cryo-EM movies of the samples were collected on a Titan Krios electron microscope

353   (Thermo Fisher Scientific) operated at an accelerating voltage of 300 kV. For the three datasets,

354   the movies were collected at a magnification of 64,000× and recorded on a K3 direct electron

355   detector (Gatan) operated in the counting mode (yielding a pixel size of 1.093 Å), and under a

356   low-dose condition in an automatic manner using EPU software (Thermo Fisher Scientific).

357   Each frame was exposed for 0.1 s, and the total accumulation time was 3 s, leading to a total

358   accumulated dose of 50.2 $e^-/\text{Å}^2$ on the specimen.

Cryo-EM 3D reconstruction

360   For each dataset, the motion correction of image stack was performed using the embedded

361   module of Motioncor2 in Relion 3.1[36,52,53] and CTF parameters were determined using

362   CTFFIND4[54] before further data processing. Unless otherwise described, the data processing

363   was performed in Relion3.1.

364   For the Omicron S dataset (Fig. S2), 600,845 particles remained after reference-free 2D

365   classification in cryoSPARC v3.3.1[37]. After 3D classification and focused 3D classification on

366   the RBD-1 region, we obtained an Omicron S-close map from 69,873 particles and an S-open

367   map from 108,509 particles. After Bayesian polishing and CTF refinement, the Omicron S-

368   open and S-close datasets were independently loaded into cryoSPARC v3.3.1[37] and refined to

369   the resolutions of 3.21 Å and 3.08 Å, respectively, using Non-uniform refinement. The overall

370   resolution was determined based on the gold-standard criterion using a Fourier shell correlation

13

371   (FSC) of 0.143. Moreover, we performed 3D Variability analysis (3DVA) on the Omicron S

372   trimer dataset in cryoSPARC to capture its continuous conformational dynamics[37].

373   For the Omicron S-ACE2 dataset (Fig. S3), 1,268,072 particles remained after reference-

374   free 2D classification. After two rounds of 3D classification and further focused 3D

375   classification on the RBD-1-ACE2 region, we obtained an Omicron S-ACE2 map from

376   141,538 particles. After Bayesian polishing and CTF refinement, the map was reconstructed to

377   3.53-Å-resolution. We then focused on RBD-2 for further classification and obtained two

378   conformations with RBD-2 in the "down" or "up" position, termed S-ACE2-C1 and -C2,

379   respectively. The two datasets were independently loaded into cryoSPARC v3.3.1 and refined

380   using Non-uniform refinement to 3.69- and 3.66-Å-resolution, respectively. The overall

381   resolution was determined based on the gold-standard criterion using a Fourier shell correlation

382   (FSC) of 0.143. Here, after obtaining the 3.53-Å-resolution map of Omicron S-ACE2, we

383   performed further local refinement on the RBD-1-ACE2 region in cryoSPARC to acquire a

384   3.67-Å-resolution map of this region.

385   For the Omicron S-S3H3 dataset (Fig. S5), similar data processing procedure was adapted

386   as described for the Omicron S dataset to obtain a 3.5-Å-resolution S-S3H3 map from 238,162

387   particles. We then carried out focused 3D classification on the RBD-1 region, followed by

388   Non-uniform refinement in cryoSPARC, and obtained a 3.48-Å-resolution S-open-S3H3 map

389   from 162,221 particles and a 3.64-Å-resolution S-close-S3H3 map from 75,900 particles. In

390   addition, after obtaining the 3.5-Å-resolution map, we performed focused 3D classification on

391   the S3H3-SD1 region of protomer 2 (highlighted by dotted orange ellipsoid), leading to a

392   dataset of 101,192 particles, which was further local refined on the S3H3-SD1 region in

393   cryoSPARC, deducing a 3.61-Å-resolution map of this region. All of the obtained maps were

394   post-processed through deepEMhancer[62].

395   **Atomic model building**

396   To build an atomic model for the Omicron S-open structure, we used the atomic model of

397   Delta S-open (PDB: 7W92) from our prior study as the initial model[32]. We first fit the model

398   into our Omicron S-open map in Chimera by rigid body fitting, then manually substituted the

399   mutations of the Omicron variant in COOT[55]. Subsequently, we flexibly refined the model

400   against our Omicron S-open map using ROSETTA[56]. Finally, we used the

401   phenix.real_space_refine module in Phenix for the S trimer model refinement against the map[57].

402   For the S-close model, we utilized the down protomer from our recent Delta S-transition (PDB:

403   7W94)[32] structure as initial template, and followed similar procedure described above for

404   model refinement. For the Omicron S-ACE2 and the local refined RBD-1-ACE2 structures,

405   we used the Delta S-ACE2 model (PDB: 7W98, 7W9I)[32] as initial template, and followed

406   similar procedure described above for model refinement. For the Omicron S-S3H3 and the

407   local refined RBD-1-S3H3 structures, we utilized our recent Beta S-S3H3 model (PDB:

408   7WDF)[29] as template, and followed similar procedure described above for model refinement.

409   The atomic models were validated using Phenix.molprobity command in Phenix. Interaction

410   interface analyses were conducted through PISA server[58].

411   UCSF Chimera and ChimeraX were applied for figure generation, rotation measurement,

412   and coulombic potential surface analysis[59,60].

Acknowledgements

Author contributions

Y.C. and Z.H. designed the experiments; Y-X. Wang expressed and purified the proteins with assistants of Z.L. and S.X.; Q.H. and W.H. performed cryo-EM data acquisitions; Q.H., W.H., J.L., and Y-F. Wang performed cryo-EM reconstructions, model buildings; C.Z. and S.X. performed biochemical analyses; J.L. Q.H., W.H., Y-F. Wang and C.Z. analyzed the data; Y.C. and Z.H. together with Q.H., J.L. W.H., Y-X. Wang and C.Z. wrote the manuscript.

Data availability

All data presented in this study are available within the figures and in the Supplementary Information. Cryo-EM maps determined for the SARS-CoV-2 Omicron S trimer have been deposited at the Electron Microscopy Data Bank with accession codes EMD-32556 and EMD-32557, and the associated atomic models have been deposited in the Protein Data Bank with accession codes 7WK2 and 7WK3 for S-open and S-close, respectively. For the S-ACE2 dataset, related cryo-EM maps have been deposited in the Electron Microscopy Data Bank with accession codes EMD-32558, EMD-32559 and EMD-32560, and the associated models have been deposited in the Protein Data Bank with accession codes 7WK4, 7WK5 and 7WK6 for S-ACE2-C1, S-ACE2-C2 and RBD-1-ACE2, respectively. For the S-S3H3 Fab dataset, related cryo-EM maps have been deposited in the Electron Microscopy Data Bank with accession codes EMD-32562, EMD-32563, and EMD-32564, and the associated models have been deposited in the Protein Data Bank with accession codes 7WK8, 7WK9 and 7WKA for SD1-S3H3, S-open-S3H3 and S-close-S3H3, respectively.
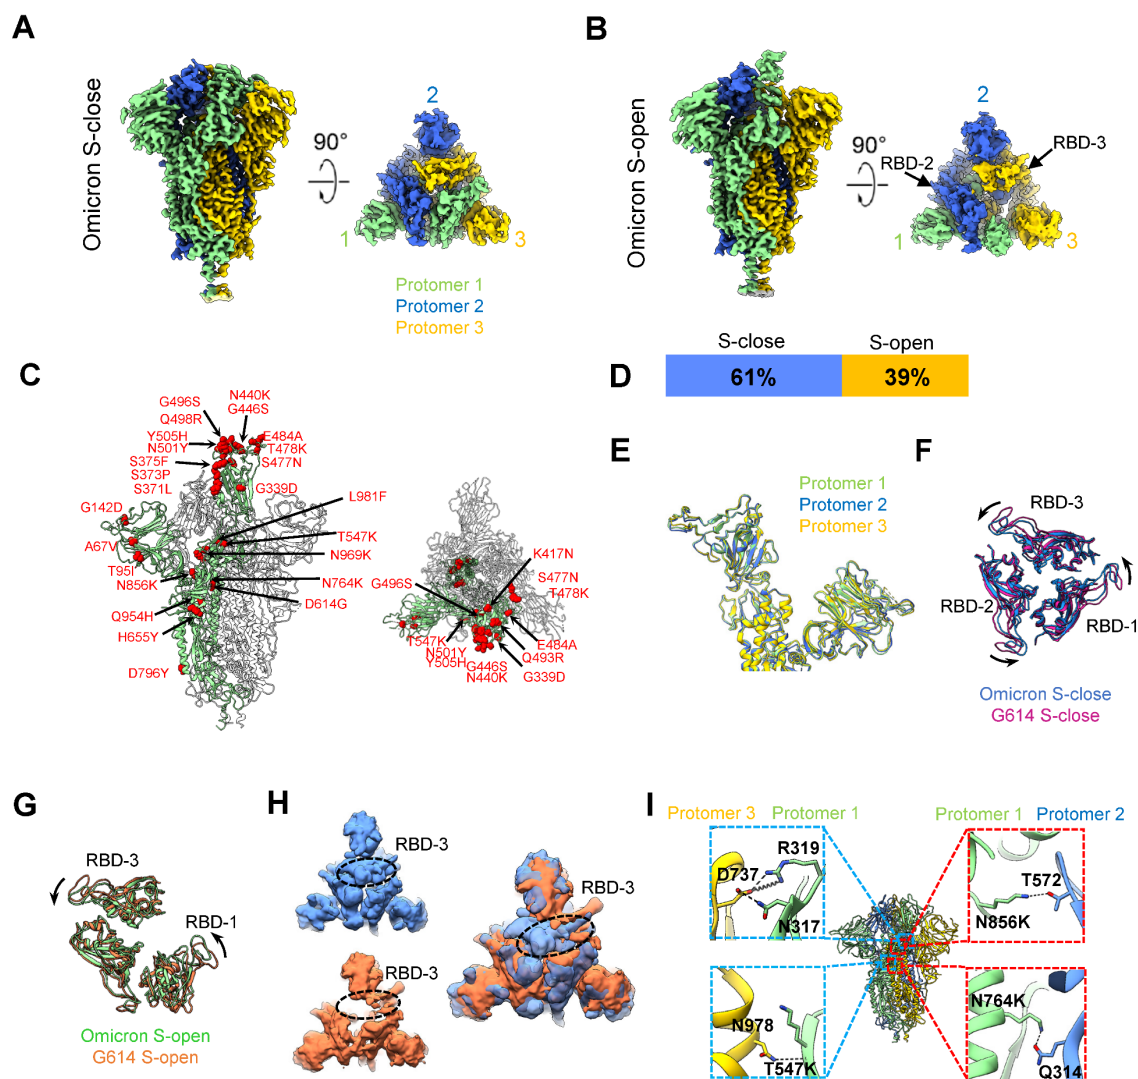

Competing interests

Z.H., S.Q.X., and C.Z. are listed as inventors on a pending patent application for MAb S3H3.

595   The other authors declare that they have no competing interests.

Figures

Fig. 1 Cryo-EM structures of the SARS-CoV-2 Omicron S trimer. (A-B) Cryo-EM maps of the Omicron S-close (A) and S-open (B) state. Protomer 1, 2, and 3 are shown in light green, royal blue, and gold, respectively, which color scheme was followed throughout. (C) Atomic model of the Omicron S-open, with mutations indicated by red sphere and labeled. (D) Population distribution of the Omicron S-close and S-open. (E) Side view of the overlaid protomers of the Omicron S-close. (F) Top view of the overlaid RBDs of the Omicron S-close (blue) and the G614 S-close (PDB: 7KRQ, purple), indicating a twist of the Omicron S-close relative to that of G614. (G) Top view of the overlaid RBDs of the Omicron S-open (light green) and the G614 S-open (PDB: 7KRR, orange), indicating a twist of the Omicron S-open relative to that of G614. (H) One representative 3DVA motions of the Omicron S dataset. The left two maps illustrate the top view of two extremes in the motion with the RBD-3 indicated by dotted black ellipsoid, and the top view of the overlaid two extreme maps is shown in the right. (I)

23

611   Newly formed H-bonds (black dashed line) and salt bridges (spring) in the interfaces of

612   protomer 1/3 and protomer 1/2 of the S-close state.

613
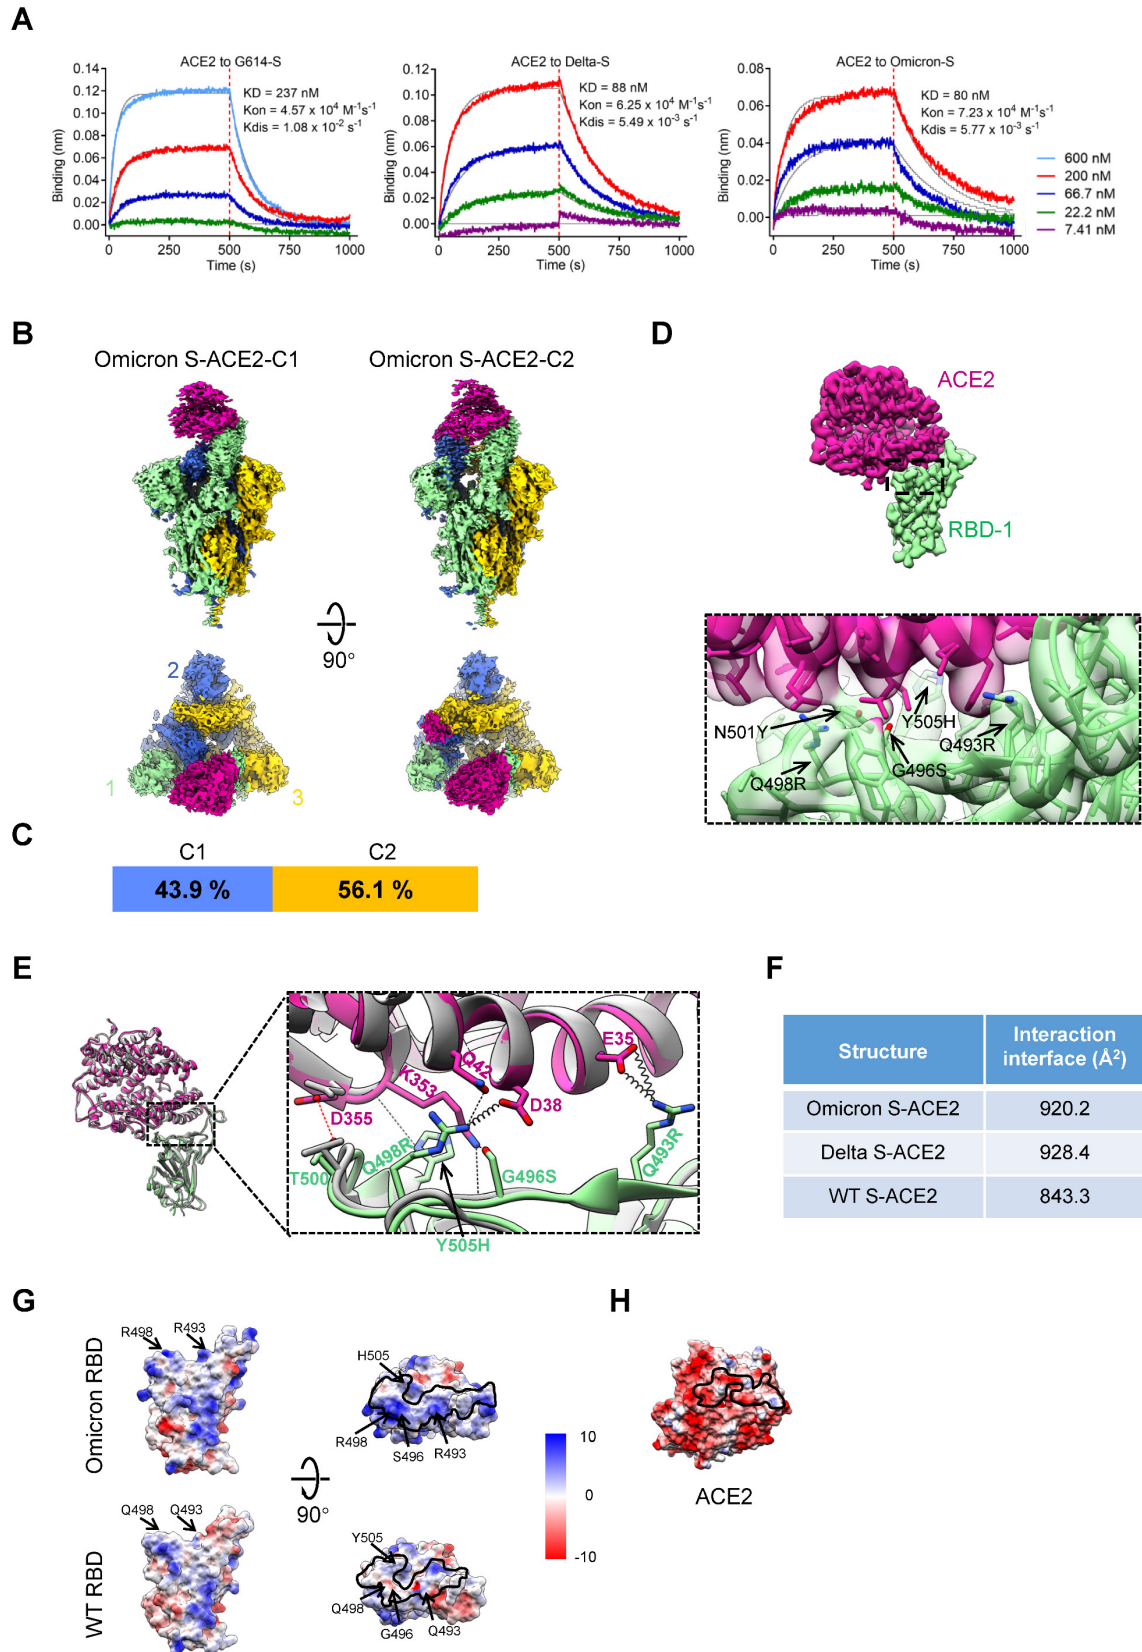

Fig. 2 Structural basis of enhanced Omicron variant S trimer/ACE2 interaction. (A) Measurement of the binding affinity between ACE2 monomer and the S trimer of the G614 (left), Delta (middle) or Omicron (right) variants using bio-layer interferometry (BLI).

618 Biotinylated S trimers were loaded onto streptavidin sensors and then allowed to interact with

619 different concentrations of ACE2 (shown on the right). Raw sensorgrams and fitting curves

620 were shown in color and gray, respectively. Association and dissociation phases were divided

621 by red dotted lines. (B) Cryo-EM maps of the Omicron S-ACE2 complex in two distinct

622 conformational states. ACE2 is shown in violet red. This color scheme is followed throughout.

623 (C) Population distribution of the Omicron S-ACE2 conformers. (D) Density map of the

624 focused refined Omicron RBD-1-ACE2 and the zoomed-in view of the RBD-ACE2 interaction

625 interface, showing the side chain densities of the Q493R, G496S, Q498R, N501Y and Y505H

626 on RBM. (E) The substituted residues R493, S496, R498 and H505 of Omicron RBM form

627 new interactions with E35, D38, Q42 and K353 of ACE2 (spring represents salt bridge, and

628 the black dashed line represents H-bond) relative to that in WT RBD-ACE2 (PDB: 6M0J, in

629 dark grey). A newly formed H-bond without substitution is shown in red dashed line. (F)

630 Interaction interface areas between ACE2 and RBD of Omicron, Delta (PDB: 7W9I), or WT

631 (PDB: 6M0J), analyzed using PISA. (G) The electrostatic surface properties of Omicron and

632 WT RBDs, with the mutated residues indicated. Black lines depict the footprint of ACE2 on

633 RBD. (H) The electrostatic surface property of ACE2, with residues in proximity to RBD-1 (<

634 4 Å) indicated (Table. S5).

B

C
Fig. 3 Neutralization and binding activities of the MAbs against SARS-CoV-2 Omicron and Delta variants. The MAbs were raised against WT RBD or S trimer proteins. (A) Neutralization IC50 values and fold changes in neutralization potency for Delta and Omicron variant pseudoviruses (PV) compared to WT pseudovirus. A minus sign (-) denotes decrease. Orange shade, more than 10-fold decrease; red shade, more than 1000-fold decrease. (B) Neutralization of the MAbs towards WT, Delta, and Omicron SARS-CoV-2 pseudoviruses. All MAbs were 4-fold serially diluted. Data are expressed as mean ± SEM of four replicate wells. (C) Binding activities of the MAbs to recombinant S trimers of the WT, Delta, and Omicron SARS-CoV-2 strains were tested by ELISA. Serially diluted S trimer proteins were coated onto the ELISA wells. Data are mean ± SD of triplicate wells.

Fig. 4 Cryo-EM analyses on the Omicron S-S3H3 Fab complex. (A-B) Side and top views of the cryo-EM map of the Omicron S-open-S3H3 (A) and S-close-S3H3 complex (B), with the heavy and light chains of S3H3 Fab in medium blue and violet red, respectively. The color scheme was followed. (C) Conformational comparison between Omicron S-open-S-S3H3 (light green) and Omicron S-open (orange), indicating a slight twist of the RBDs of S-open-S3H3 and the downward rotations of RBD-1 (up to 9.1°) and SD1. (D) Model-map fitting of

655   the focus-refined Omicron SD1-S3H3 structure, and the zoomed-in view of the Omicron SD1-

656   S3H3 interaction interface. The sidechain densities at the interface were well resolved. (E) The

657   S3H3 binding on SD1 of protomer 2. (F) The interaction involved regions/residues between

658   S3H3 Fab and SD1 with T547K labeled. (G) The SD1-S3H3 interaction interface analyzed

659   using PISA, with major involved structural elements labeled (spring represents salt bridge, and

660   the black dashed line represents H-bond).
