22 **SUMMARY**

23

24 The protective human antibody response to the severe acute respiratory syndrome coronavirus 2

25 (SARS-CoV-2) virus focuses on the spike (S) protein which decorates the virion surface and

26 mediates cell binding and entry. Most SARS-CoV-2 protective antibodies target the receptor-

27 binding domain or a single dominant epitope ('supersite') on the N terminal domain (NTD).

28 Here, using the single B cell technology LIBRA-seq, we isolated a large panel of NTD-reactive

29 and SARS-CoV-2 neutralizing antibodies from an individual who had recovered from COVID-

30 19. We found that neutralizing antibodies to the NTD supersite commonly are encoded by the

31 *IGHV1-24* gene, forming a genetic cluster that represents a public B cell clonotype. However, we

32 also discovered a rare human antibody, COV2-3434, that recognizes a site of vulnerability on the

33 SARS-CoV-2 S protein in the trimer interface and possesses a distinct class of functional

34 activity. COV2-3434 disrupted the integrity of S protein trimers, inhibited cell-to-cell spread of

35 virus in culture, and conferred protection in human ACE2 transgenic mice against SARS-CoV-2

36 challenge. This study provides insight about antibody targeting of the S protein trimer interface

37 region, suggesting this region may be a site of virus vulnerability.

39 **Keywords**: Coronavirus; SARS-CoV-2; Antibodies, Neutralizing; N-terminal domain.

40   **INTRODUCTION**

41

42   During the COVID-19 pandemic, more than 150 vaccine candidates have been developed, but

43   only a few have been licensed. Most licensed vaccines encode the full-length spike (S) protein

44   including two stabilizing proline mutations (S2P) of SARS-CoV-2 (Baden et al., 2021; Polack

45   et al., 2020; Turner et al., 2021c) and have proven effective in protecting against SARS-CoV-

46   2 disease. Although SARS-CoV-2 vaccines have been developed at unprecedented speed,

47   several questions remain about efficacy and the durability of protective immunity associated

48   with serum neutralizing antibodies generated against the S protein. Efficacy studies are

49   complicated by the emergence of SARS-CoV-2 variants of concern (VOC) that can escape

50   some neutralizing antibodies. Antibodies that neutralize SARS-COV-2 VOC have been

51   studied broadly by many groups, both in terms of their potency and structure (Barnes et al.,

52   2020; Baum et al., 2020; Cerutti et al., 2021b; Chen et al., 2021b; Chi et al., 2020; Dong et

53   al., 2021; Hansen et al., 2020; McCallum et al., 2021; Pinto et al., 2020; Rogers et al., 2020;

54   Shi et al., 2020; Suryadevara et al., 2021; Turner et al., 2021b; Zost et al., 2020a). Similarly, it

55   has been reported that unrelated individuals can produce genetically and functionally similar

56   clones of antibodies ("public clonotypes") following infection or vaccination ((Chen et al.,

57   2021a; Robbiani et al., 2020; Soto et al., 2019; Yuan et al., 2020)*18-22*).

58

59   The receptor binding domain (RBD) of the S protein interacts with angiotensin-converting

60   enzyme 2 (ACE2). In addition, the N-terminal domain (NTD) of S has been proposed to

61   cooperate with receptors or co-receptors, such as dendritic cell-specific intercellular adhesion

3

62   molecule-3-grabbing non-integrin (DC-SIGN or CD209), neuropilin-1 (NRP-1), and liver-

63   /lymph-node-specific intracellular adhesion molecules-3 grabbing non-integrin (L-SIGN or

64   CD209L) to mediate viral attachment and enable SARS-CoV-2 infection via the established

65   ACE2 receptor pathway (Amraei et al., 2021; Cantuti-Castelvetri et al., 2020; Daly et al.,

66   2020; Lempp et al., 2021). Furthermore, the NTD of SARS-CoV-2 spike reportedly binds

67   biliverdin by recruitment of tetrapyrrole rings, to evade neutralization of SARS-CoV-2 by

68   some antibodies (Rosa et al., 2021). SARS-CoV-2 S appears to exhibit conformational

69   flexibility of divergent loop regions in the NTD to accommodate diverse glycan-rich host

70   sialosides that may allow it to infect host cells with wide tissue tropism (Awasthi et al., 2020).

71   Taken together, our understanding of the functional qualities of the human antibody response

72   against NTD is incomplete. We and other groups previously have identified potently

73   neutralizing NTD-specific mAbs targeting one major antigenic site (Cerutti et al., 2021b; Chi

74   et al., 2020; McCallum et al., 2021; Suryadevara et al., 2021; Voss et al., 2021; Wu et al.,

75   2020). Here, using the single-B-cell barcoding LIBRA-seq antibody discovery technology, we

76   performed targeted discovery of NTD-reactive antibodies from an individual who had

77   recovered from a previous SARS-CoV-2 infection. Our results indicate that a dominant

78   human B cell response to that major NTD antigenic site comprises clones encoded by

79   common variable gene segments (*i.e.*, constitute a "public clonotype"). The scale of antibody

80   discovery possible with LIBRA-seq also allowed us to identify a rare clone with unusual

81   specificity and function.

82

83   **RESULTS**

84

85   **SARS-CoV-2 infection induces a strong response against NTD and durable neutralization**

86   **titers.** Peripheral blood samples were obtained following written informed consent from four

87   subjects (D1988, D1989, D1995 and D1951) infected in the United States who tested PCR-

88   positive for SARS-CoV-2 infection and one healthy donor (D269) who served as a negative

89   control (**Table S1**). We isolated plasma or serum specimens from the five individuals and

90   performed serum/plasma antibody ELISA binding assays using soluble proline-stabilized S

91   ectodomain (S2P$_{ecto}$), RBD, or NTD protein from SARS-CoV-2 or S2P$_{ecto}$ protein from SARS-

92   CoV. All subjects (except the negative control) had circulating antibodies that recognized each of

93   the proteins tested, with the greatest reactivity against the SARS-CoV-2 S2P$_{ecto}$, RBD and NTD

94   proteins (**Fig. 1A**). The serum antibody reactivity of one individual (D1989) was highest against

95   the SARS-CoV-2 NTD protein (**Fig. 1A**). Consequently, we focused our efforts on identifying B

96   cells from the blood samples of this individual, using sequential collections on day 18, 28, 58

97   and day 90 after onset of symptoms. This individual also possessed high serum neutralizing

98   antibody titers, as determined in an assay using a chimeric vesicular stomatitis virus (VSV)

99   displaying SARS-CoV-2 S protein (VSV-S) in a real time cell analysis (RTCA) method (10)

100   (**Fig. 1B**). The plasma neutralizing titer was high (NT$_{50}$= 1:258) even three months after recovery

101   from SARS-CoV-2 infection. To corroborate the VSV-S-based neutralization results, we also

102   performed a serum-antibody focus reduction neutralization test (FRNT) using an authentic

103   SARS-CoV-2 strain (WA/1/2020). The authentic virus assay gave similar results to the VSV-

104   based assay (**Fig. 1C**).

105

106   **LIBRA-seq identifies antigen-specific B cells with high NTD specificity**. Next, we used the

107   LIBRA-seq (*Linking B Cell receptor to antigen specificity through sequencing*) method (Setliff

108   et al., 2019) to identify NTD-reactive B cells. This   high-throughput technology enables

109   determination of B cell receptor sequence and antigen reactivity at single-cell level. The LIBRA-

110   seq antigen screening library included SARS-CoV-2 S protein stabilized in a prefusion

111   conformation (S6P$_{ecto}$) and NTD from SARS-CoV-2 (2019-nCoV), along with antigens from

112   other coronavirus strains and negative control antigens. We identified 347 NTD-specific B cells

113   from individual D1989 (day112). We recovered 108 B cells which expressed unique V_H–JH–

114   CDRH3–V_L–J_L–CDRL3 clonotypes and gave LIBRA-seq scores above a threshold of 1 for

115   rNTD (**Fig. 2A**), and we were able to express 102 of these sequences as human mAbs. To

116   confirm the antigen specificity predicted by the LIBRA-seq score, we tested all expressed mAbs

117   for binding in ELISA to recombinant monomeric RBD or NTD of SARS-CoV-2 or trimeric

118   S6P$_{ecto}$ of SARS-CoV-2 or trimeric S2P$_{ecto}$ of SARS-CoV proteins. We confirmed the predicted

119   antigen specificity for greater than 90% of the clones (**Fig. 2B**). Most antibodies recognized

120   NTD protein, except for COV2-3454 which recognized RBD (**Fig. 2B**).

121

122   Additionally, using the RTCA method, we performed high-throughput neutralization assays with

123   VSV-S and identified 9 mAbs that showed either full (100%) or partial (50 to 80%) neutralizing

124   capacity (**Fig. 2B**). Next, we analyzed the sequences of the variable region genes for the 102

125   expressed antibodies to assess the genetic diversity of antigen-specific B cell clonotypes

126   discovered. The expressed antibodies had diverse sequence features, including varied V- and J-

127   gene usage, CDR3 lengths, and somatic hypermutation levels for both the heavy and light chains

128   (**Fig. S1a**). After clustering these clones based on the inferred immunoglobulin heavy variable

129   (IGHV) gene, we noted that the *IGHV1-24* and *IGHV1-69* variable gene segments were used

130 frequently in this individual's response (**Fig. S1b**). Five of the nine neutralizing mAbs are

131 encoded by the *IGHV1-24* gene segment and are clonally unrelated (**Fig. 2C**).

132

133 **Potently neutralizinge antibodies against NTD belong to public clonotypes**.

134 Next, we determined the binding activity of the panel of NTD-reactive neutralizing antibodies.

135 Using serial dilution studies, we determined the half-maximum effective concentration (EC_{50}) for

136 binding to the $S6P_{ecto}$ trimer protein, in comparison with a known NTD-reactive mAb (4A8) or a

137 negative control dengue-specific antibody (rDENV-2D22). NTD-reactive neutralizing antibodies

138 exhibited varied binding profiles with a diverse range of EC_{50} values (**Fig. 3A**). We also tested

139 the panel of antibodies for binding to cell-surface-displayed S protein on SARS-CoV-2-infected

140 cells according to the gating strategy shown in **Fig S2**. Unexpectedly, the NTD-targeting mAbs

141 stained infected cells with greater intensity (higher median fluorescence intensity [MFI]) than a

142 previously described high-affinity RBD-reactive potently neutralizing mAb (COV2-2196) (Zost

143 et al., 2020a) (**Fig. 3B**). We also determined the inhibitory potency for representative mAbs in

144 the quantitative VSV-S-based neutralization assay (**Fig. 3C**). These results confirmed that the

145 LIBRA-seq technology efficiently identifies mAbs with the correct antigen specificity and that

146 some of the NTD-reactive mAbs potently neutralize VSV-S infection based on RTCA

147 neutralization ((Suryadevara et al., 2021; Zost et al., 2020a). Next, we chose chose COV2-3434

148 for further study with FRNT as it showed a distinct phenotype both in binding and rVSV

149 neutralization. We performed FRNTs for mAb COV2-3434 using strains SARS-CoV-2 D614G

150 and chimeric strains expressing the B.1.351 (Beta) spike in the WA1/2020 background (Wash-B

151 1.351) (Chen et al., 2021b). COV2-3434 neutralized both strains of SARS-CoV-2 in a dose-

152 dependent manner, with half-maximal inhibitory (IC_{50}) values of 5.5 or 32 µg/mL, respectively

153   (**Fig. 3D**). A comprehensive analysis of antibody variable gene sequences for SARS-CoV-2

154   human mAbs revealed that the *IGHV1-24* gene segment is frequently used by vaccinated or

155   convalescent individuals when targeting the NTD (**Table S2, Fig. S3**). Nevertheless, the clones

156   recovered here were unique with diverse gene usage for both heavy and light chains. There was

157   no bias for a particular HCDR3 length that confers NTD-specificity. Additionally, the *IGHV1-69*

158   and *IGHV3-53* gene segments are over-represented in both RBD- and NTD-specific antibodies

159   isolated from convalescent subjects. Of note, the *IGHV1-69* gene-encoded antibodies that reacted

160   with NTD did *not* neutralize VSV-S, and the other V_H genes used (*IGHV1-2*, *IGHV3-23* and

161   *IGHV3-53*) encoded clones with only moderate neutralizing capacity. Thus, the most potently

162   neutralizing NTD-reactive antibodies isolated here were encoded by *IGHV1-24*.

163

164   To determine if the function of *IGHV1-24*-encoded antibodies identified in this study was due to

165   germline-encoded reactivity or the result of somatic mutations, we engineered 'germline

166   reversion' (GR) recombinant antibodies that were reverted at residues that differed from the

167   germline gene segments either in the heavy chain (GR-HC) or in both heavy and light chains

168   (GR). After alignment of the sequences of *IGHV1-24*-encoded clones the with germline gene

169   segment *IGHV1-24*, we chose the mAb COV2-3443 for further study, as it was the antibody with

170   the fewest somatic mutations. We tested if the GR mAb shared similar functional properties with

171   its somatically-mutated counterparts for binding to S protein or VSV-S neutralization. The

172   COV2-3443 GR-HC mAb retained some binding and neutralization capacity, whereas COV2-

173   3443 GR completely lost binding and neutralization capacity, suggesting that the functional

174   activities required some or all of the somatic mutations present in the matured antibody (**Fig. 3**

175   **E, F**).

176

177 **COV2-3434 maps to a distinct site from the NTD supersite**. We next defined antigenic sites

178 on the NTD by competition-binding analysis. We used SARS-CoV-2 $6P_{ecto}$ protein to screen for

179 NTD-reactive neutralizing mAbs that competed for binding with each other or with the

180 previously described NTD-reactive mAbs COV2-2676 and COV2-2489 that recognize known

181 epitope on NTD (10). We also used the previously described RBD-reactive neutralizing (COV2-

182 2196 and COV2-2130) or non-neutralizing (rCR3022) mAbs as controls. We identified two

183 groups of competing mAbs in the NTD (**Fig. 4A**). The first group competed for binding to the

184 known NTD supersite, which we and others have described previously (Cerutti et al., 2021b; Chi

185 et al., 2020; McCallum et al., 2021; Suryadevara et al., 2021). The second competition group

186 contains a single mAb (COV2-3434) that bound to a site distinct from the epitope of all other

187 NTD-reactive mAbs (**Fig. 4A**). We also tested competition of COV2-3434 mAb with the

188 recently reported antibody 5-7, which binds a hydrobphobic site on NTD. Our mAb COV2-3434

189 did not compete for binding with mAb 5-7 either on SARS-CoV2-$6P_{ecto}$ or on NTD, revealing

190 the COV2-3434 site is unique (**Fig. S4**).

191

192 **COV2-3434 exhibits trimer-disrupting propertie**s. To further probe the binding sites for these

193 mAbs, we used negative-stain electron microscopy (nsEM) to image a stabilized trimeric form of

194 the ectodomain of S protein ($S6P_{ecto}$ trimer) in complex with Fab fragment forms of COV2-3439

195 or COV2-3434. We chose COV2-3439 as a representative mAb from the first competition group,

196 as it was the most potently neutralizing antibody against VSV-S. COV2-3439 bound to the NTD

197 and recognized the 'closed' conformational state of the $S6P_{ecto}$ trimer. We confirmed that the

198 COV2-3439 antibody binds to the previously noted antigenic "supersite" on the NTD of the

199   S6P$_{ecto}$ trimer by overlaying the nsEM maps of the COV2-3439 Fab/S protein complex with our

200   previously published COV2-2676 Fab/S complex (**Fig. 4B**).

201

202   Unexpectedly, we did not observe intact S protein trimers following a one-hour incubation with

203   saturating concentrations of COV2-3434 Fab fragments. Shorter incubation times with Fabs (1, 5

204   or 30 mins) showed more intact trimers in the grids (**Fig. 4C**). Representative 2D images

205   revealed that Fabs were bound to the S protomers, suggesting that Fabs recognize an epitope that

206   is not present or accessible on an intact S trimer (**Fig. 4D**). Although the 2D images are

207   revealing, we could not create reconstructions of the Fab-protomers, since there were very

208   limited views of the complexes. The data are consistent with a trimer-disruption mechanism in

209   which binding of the COV2-3434 Fab to a partially occluded epitope drives the disruption of S

210   protein trimer.

211

212   We next defined the COV2-3434 and COV2-3439 epitopes at the amino acid level using 2

213   complementary methods: alanine-scanning loss-of-binding experiments and cell-surface S

214   protein display method. Screening of the NTD alanine-scan library identified primary residues

215   F43, F175, L176 and L226 as critical for binding of COV2-3434 (**Fig. 5A**), whereas for COV2-

216   3439 residues R102, Y145, K147, W152, R246, Y248, P251 and G252 were identified **(Fig. S5).**

217   None of these single-residue alanine mutants affected binding of the control NTD-reactive mAb

218   COV2-2305 (**Fig. 5B**). As an alternative approach to learn more about the epitope recognized

219   this trimer-disrupting antibody, we generated complexes of NTD subdomain with Fabs of

220   COV2-3434 and COV2-3439. Intrestingly, in NS-EM we noticed that the COV2-3434 Fab binds

221   NTD at a 90° angle to that of the supersite-binding COV2-3439 Fab (**Fig. 5C**). Moreover, when

222   we overlaid this double Fab + rNTD complex onto that of the trimeric spike complex (7C2L

223   model), COV2-3434 Fab tangentially clashed with interface of RBD and NTD (**Fig. 5C**).

224   Modeling of double Fab and NTD complexes onto the spike monomer, dimer and trimer when

225   RBD is open enabled us to locate Fab binding more precisely and suggested that the epitope

226   recognized by COV2-3434 is occluded (**Fig. S6**). Recently, it was reported that the NTD of

227   SARS-CoV-2 spike binds biliverdin and polysorbate 80 by recruitment of tetrapyrrole rings to

228   evade antibody neutralization. However, our neutralization assays in the presence of biliverdin

229   or polysorbate 80 did not affect COV2-3434 neutralization of VSV-S (**Fig. S7**), again suggesting

230   this epitope is distinct. Additional structural studies are needed to determine sturcural basis for

231   the trimer-disrupting phenotype of mAbs binding to this epitope.

232

233   The S protein exhibits high flexibility between domains and can exist in different conformations,

234   allowing the immune system to target distinct epitopes and structural states (Henderson et al.,

235   2020). Henderson *et al*. showed that conformations of the S protein can be controlled via rational

236   design using expressed soluble ectodomains of the S proteins, in which the three RBDs are either

237   locked in the all-RBDs 'down' position (S6P$_{ecto}$-2C) or adopt 'up' state (S6P$_{ecto}$) conformations

238   (Henderson et al., 2020). We hypothesized that the COV2-3434 binding site is accessible only

239   when the RBD adopts an 'up' state conformation of S6P$_{ecto}$. To test this model, we quantified

240   binding of COV2-3434 to S6P$_{ecto}$ or S6P$_{ecto}$-2C proteins by ELISA. For comparison, we also

241   included a mAb that binds to RBD in either the up or down conformational state (COV2-2130), a

242   mAb that binds to NTD (COV2-2676), and the negative-control dengue mAb DENV-r2D22. As

243   expected, the binding of COV2-3434 to S6P$_{ecto}$-2C protein was reduced, confirming that the

11

244   epitope is cryptic and only accessible when at least one RBD is in its 'up' conformation (**Fig.**

245   **5D**).

246

247   **SARS-CoV-2 mRNA vaccines can induce trimer-disrupting antibodies**. Although we

248   identified a new antigenic site by isolating COV2-3434 from a SARS-CoV-2 convalescent

249   donor, it is uncertain if this class of antibodies forms a major part of the humoral immune

250   response to the S protein trimer. To address this question, we performed a competition-binding

251   ELISA with serum antibody and COV2-3434. Serum antibodies from each of 4 naturally SARS-

252   CoV-2 infected individuals or from each of 5 individuals before or after SARS-CoV-2 mRNA

253   vaccination were tested. We observed up to 90% serum antibody competition with COV2-3434

254   in 3 donors tested following vaccination, indicating that in some individuals SARS-CoV-2

255   mRNA vaccination generates high levels of S protein trimer-interface (TI) specific antibodies or

256   antibodies that compete with TI antibodies (**Fig. 5E**). In contrast, we did not observe this level of

257   competition with COV2-3434 in serum from convalescent donors. Taken together, these results

258   suggest that S trimer interface antibodies may be more common in the serum of vaccinated than

259   infected individuals. The reason this class of antibodies was observed in the serum of vaccinees

260   but not convalescent individuals is not clear, although engineered vaccine S antigen differs from

261   the natural S protein in that the "pre-fusion" S conformation was stabilized in the vaccine

262   construct by mutagenesis.

263

264   **COV2-3434 inhibits VOC and confers partial protection against SARS-CoV-2 infection**.

265   Identification of neutralizing mAbs that bind to distinct antigenic sites on S proteins might help

266   to avoid escape from neutralization by VOC. To address this idea, we used VSV-S viruses

267   expressing SARS-CoV-2 S protein variants that were resistant to neutralization by the RBD-

268   specific antibodies COV2-2479, COV2-2499 or COV2-2130 (Greaney et al., 2021) or resistant

269   to the NTD-specific antibodies COV2-2676 and COV2-2489 (Suryadevara et al., 2021). The

270   COV2-3434 mAb neutralized all escape VSV viruses at the higher concentration tested (**Fig.**

271   **6A**).

272

273   We next assessed the ability of COV2-3434 to protect K18-hACE2-transgenic mice following

274   viral challenge with SARS-CoV-2 (Golden et al., 2020; Oladunni et al., 2020; Winkler et al.,

275   2021). One day prior to virus inoculation, we passively transferred ~10 mg/kg (200 µg/mouse) of

276   COV2-2196 (RBD-specific), COV2-3434 (NTD-specific) or DENV-r2D22 (negative control)

277   mAbs. Mice that received r2D22 lost more than 20% initial body weight. Animals treated with

278   the RBD mAb COV2-2196 were completely protected from weight loss. COV2-3434 conferred

279   intermediate protection against weight loss (**Fig. 6B**). Pre-treatment with COV2-3434 also

280   partially protected against viral burden, with a 7-fold lower level of infectious virus in the lung

281   compared to the negative-control antibody (**Fig 6C**). We repeated the study by passively

282   transferring a higher dose (1 mg/mouse) of COV2-2196 (RBD-specific), COV2-3434 (NTD-

283   specific) or DENV-r2D22 (negative control) mAbs, and again saw a comparable reduction of

284   viral titers in the lungs and nasal turbinates (**Fig. S8**).

285 **DISCUSSION**

286   Human neutralizing mAbs to SARS-CoV-2 isolated from recovered COVID-19 individuals are

287   of great importance as potential therapeutic candidates. The continued investigation into

288   identifying protective epitopes using mAbs as we have done here may inform future structure-

289   based rational design of next-generation SARS-CoV-2 vaccines by revealing protective sites

290   whose structure should be preserved in engineered vaccine antigens. Most potently neutralizing

291   SARS-CoV-2 mAbs discovered to date recognize the RBD region, while some moderately

292   neutralizing NTD-directed mAbs also were identified (Barnes et al., 2020; Baum et al., 2020;

293   Cerutti et al., 2021b; Chen et al., 2021b; Chi et al., 2020; Dong et al., 2021; Hansen et al., 2020;

294   McCallum et al., 2021; Pinto et al., 2020; Rogers et al., 2020; Shi et al., 2020; Suryadevara et al.,

295   2021; Turner et al., 2021c; Zost et al., 2020a). All of the NTD-reactive mAbs reported to date

296   have lost their neutralizing capacity against certain emerging VOC. The majority of antibodies

297   identified against NTD target an antigenic site termed the NTD 'supersite' (Cerutti et al., 2021b;

298   Chi et al., 2020; McCallum et al., 2021; Suryadevara et al., 2021). Although a few other

299   antigenic sites on NTD have been described, mAbs binding to these sites generally were non-

300   neutralizing. The frequent occurrence of mutations in the NTD of multiple circulating SARS-

301   CoV-2 variants suggests that the NTD is under strong selective pressure from the host humoral

302   immune response (Weisblum et al., 2020). Furthermore, antigenic changes caused by deletions in

303   NTD have been identified within the antigenic supersite of viruses shed by immunocompromised

304   hosts (Avanzato et al., 2020; Choi et al., 2020; McCarthy et al., 2021).

305

306   In this work, we report the isolation and characterization of SARS-CoV-2 neutralizing mAbs

307   targeting the NTD using LIBRA-seq. We used NTD, a domain cloned from the full-length spike,

14

308   as antigen bait for isolating memory B cells from a convalescent donor. More than 90% of the

309   clones we selected by LIBRA-seq for expression reacted exclusively with NTD, and these

310   findings also were supported by reactivity studies with the SARS-CoV-2 S6P$_{ecto}$ domain. A

311   subset of eight NTD-targeting antibodies selected by LIBRA-seq was neutralizing. Several of the

312   mAbs potently neutralized VSV-S. The primary target for most of the neutralizing antibodies

313   identified is the NTD 'supersite', as previously described by several groups (Cerutti et al.,

314   2021b; McCallum et al., 2021; Shi et al., 2020; Suryadevara et al., 2021). Most of these NTD-

315   supersite-targeting antibodies appear to be members of a public clonotype. Although diverse

316   public clonotypes recognizing RBD or NTD have been described, we identified an *IGHV1-24-*

317   encoded clonotype that seems to dominate the response to NTD. Clones from this public

318   clonotype are seen following both vaccination and infection.

319

320   We also identified an antibody designated COV2-3434 that recognizes a distinct antigenic site on

321   NTD that may represent a new site of vulnerability on SARS-CoV-2 spike. COV2-3434 binds to

322   recombinant SARS-CoV-2 S6P$_{ecto}$ protein weakly in ELISA, but more avidly to cell-surface-

323   displayed spike on Vero cells infected with VSV-S. In contrast to other NTD-reactive potently

324   neutralizing antibodies, COV2-3434 weakly inhibits infection of VSV-S and authentic SARS-

325   CoV-2 viruses. With these distinctive phenotypes, we tried to learn more about the mode of

326   recognition of this antigenic site by ns-EM of antigen-antibody complexes. Unexpectedly, we

327   found that COV2-3434 Fab disrupted SARS-CoV-2 S trimers when added to make spike-Fab

328   complexes. This finding of trimer disassociation mediated by COV2-3434 revealed a potential

329   site of vulnerability hidden in the S trimer interface. Similarly, a recently identified NTD-

330   reactive neutralizing antibody called 5-7 also recognizes a distinct antigenic site within the NTD,

331   antibodies of this class insert an antibody hypervariable loop into the exposed hydrophobic

332   pocket between the two sheets of the NTD β-sandwich (Cerutti et al., 2021a). This pocket was

333   described previously as the binding site for metabolites such as heme with hydrophobic

334   properties (Rosa et al., 2021). Our alanine scan mutagenesis data reveals that COV2-3434 shares

335   some contact residues with mAb 5-7 including F175 and L176, while L226 is barely deeper than

336   175 and 176. However, COV2-3434 also lost its binding capacity when deeper pocket residues

337   F43 and was mutated. We noted that in the spike trimer, residue F43 lies at an interface between

338   adjacent monomers such that MAb binding could intiate a destabilization of the trimer.

339

340   Recently several reports about mAbs targeting the trimer interface of multiple viral antigens have

341   been published. For instance, the non-neutralizing influenza mAbs FluA20 and 5J6 that

342   recognize the hemagglutinin trimer interface (Bangaru et al., 2019; Zost et al., 2021) were

343   identified from influenza-vaccinated individuals. Also, epitope mapping using polyclonal serum

344   from vaccinated rabbits identified antibodies recognizing the HIV envelope glycoprotein trimer

345   interface (Turner et al., 2021a). Similarly, the epitope for a neutralizing mAb for human

346   metapneumovirus (MPV458) lies within the trimeric interface of pneumovirus fusion proteins

347   (Huang et al., 2020).

348

349   COV2-3434 is a rare SARS-CoV-2 S trimer interface antibody that mediates virus neutralization.

350   Our COV2-3434 competition data suggest that this class of mAbs may be common in the serum

351   of some vaccinated individuals. Hence, surveillance of this class of antibodies and understanding

352   its contribution to vaccine protection is important, particularly in the context of emergence of

353 new VOC and updated vaccine designs. While these trimer-interface mAbs do not all neutralize

354 virus *in vitro*, passive transfer of these mAbs can mitigate severe disease. For example, the

355 FluA20 mAb did not neutralize influenza, but still conferred protection in mice challenged with

356 H1N1 A/California/04/2009 virus (Bangaru et al., 2019). Here, the moderately neutralizing

357 COV2-3434 conferred partial protection against weight loss and lung infection in mice when

358 given as prophylaxis.

359 In summary, using LIBRA-seq, we identified the mAb COV2-3434 that binds to a distinct

360 antigenic site on the NTD and disassociates S trimers by contacting critical residues in a cryptic

361 hydrophobic pocket in the S trimer interface.

394 **FIGURE LEGENDS**

395

396 **Figure 1. Characterization of SARS-CoV-2 antibodies in convalescent patient samples.**

397 **A.** Serum or plasma antibody reactivity for the four SARS-CoV-2 convalescent patients and one

398 non-immune healthy control subject were assessed by ELISA using SARS-CoV-2 $S6P_{ecto}$, S_{RBD},

399 S_{NTD}, SARS-CoV $S2P_{ecto}$ or PBS. Optical density was measured with a 450-nm filter (OD_{450})

400 using a microplate reader. Error bars, s.d.; data are representative of at least two independent

401 experiments performed in technical duplicate. **B.** Plasma or serum neutralizing activity against

402 the VSV-S for SARS-CoV-2 convalescent donor 1989 on day 18, 28, 56 or day 90 in an RTCA

403 neutralization assay. Data represent two experiments performed in technical duplicate. **C.** Plasma

404 or serum neutralizing activity against the WA1/2020 strain SARS-CoV-2 for convalescent donor

405 1989 on day 18, 28, 56 or day 90 using a FRNT. Data represent experiments performed in

406 technical duplicate. Data represent two experiments performed in technical duplicate.

19

407 **Figure 2. Reactivity, functional and genetic features of 102 human mAbs identified using**

408 **LIBRA-seq.**

409 **A.** LIBRA seq scores for all cells per experiment are shown as black circles from three different

410 LIBRA-seq runs. Antibodies that demonstrated either full and partial neutralization in the high-

411 throughput RTCA assay are highlighted in green or purple, respectively.

412 **B.** MAb specificity or reactivity for each of four S proteins or subdomains. The figure shows a

413 heatmap for binding of 102 mAbs expressed recombinantly, representing OD values collected at

414 450 nm for each antigen (range, 0.5 to 4.0). White indicates a lack of detectable binding, blue

415 indicates binding, and darker blue indicates higher OD values. To the right are the antibody

416 numbers that demonstrated either full or partial neutralization in the high-throughput RTCA

417 assay, highlighted in green or purple, respectively.

418 **C.** Genetic characteristics for mAbs that demonstrated either full or partial neutralization along

419 with their ELISA reactivity; numbers in the boxes represent OD values collected at 450 nm

420 (range, 0.5 to 4.0) and LIBRA-seq scores for each antigen. White fill indicates no or low

421 reactivity, red (ELISA) or purple (LIBRA-seq) fill represent reactivity for the respective

422 antigens.

423

20

Figure 3. Activity of neutralizing mAbs against SARS-CoV-2.

A. ELISA binding to SARS-CoV-2 S6P$_{ecto}$ protein was measured by absorbance at 450 nm. Antibody concentrations starting at 20 µg/mL were used and titrated two-fold. Calculated EC$_{50}$ values are shown on the graph. Error bars indicate standard deviation; data represent at least two independent experiments performed in technical duplicate.

B. Binding to the surface of VSV-S-infected Vero cells was measured using flow cytometry and median florescence intensity values were determined for dose-response binding curves. Antibody was diluted 3-fold staring from 20 µg/mL. Data represent two experiments performed in technical triplicate.

C. VSV-S neutralization curves for mAbs that were expressed after high throughput RTCA neutralization conformation. Calculated IC$_{50}$ values are shown on the graph. Error bars indicate standard deviation; data represent at least two independent experiments performed in technical duplicate.

D. Neutralization curves for COV2-3434 or COV2-2196 against SARS-CoV-2 virus. Calculated IC$_{50}$ values are shown on the graph. Error bars indicate standard deviation; data represent at least two independent experiments performed in technical duplicate.

E. Germline-revertant (GR) COV2-3443 antibody reactivity and functional activity, ELISA binding to SARS-CoV-2 S6P$_{ecto}$ protein was measured by absorbance at 450 nm and binding to the surface of VSV-S-infected Vero cells was measured using flow cytometry and median florescence intensity values were determined for dose response binding curves.

444   **F.** VSV-S neutralization curves for germline-revertant COV2-3443 antibody. Error bars indicate

445   standard deviation; data represent at least two independent experiments performed in technical

446   duplicate.

447

448 **Figure 4. Epitope identification and structural characterization of COV2-3439 and COV2-**

449 **3434 antibodies.**

450 **A.** Competition of the panel of neutralizing mAbs with previously mapped antibodies COV2-

451 2130, COV2-2196, COV2-2676, COV2-2489, r4A8 or rCR3022. Unlabeled antibodies applied

452 to antigen first are indicated on the left, while biotinylated antibodies that were added to antigen-

453 coated wells second are listed across the top. The number in each box represents the percent

454 competition binding of the biotinylated antibody in the presence of the indicated competing

455 antibody. Heat map colors range from dark grey (100% binding of the biotinylated antibody) to

456 white (0% or no binding of the biotinylated antibody). The experiment was performed in

457 biological replicate. Biological replicate from representative single experiment shown.

458 **B.** Negative-stain EM of SARS-CoV-2 S6P$_{ecto}$ protein in complex with COV2-3439 Fab. Side

459 view and top view of superimposed 3D volume COV2-3439 Fab–S6P$_{ecto}$ closed trimer (S protein

460 model PDB:7JJI) complexes as visualized by negative-stain EM for COV2-2676 Fab model in

461 gold, COV2-2489 Fab model in grey. At the bottom, negative-stain 2D classes of SARS-CoV-2

462 S protein incubated with COV2-3439 Fab are shown. Data are from a single experiment; detailed

463 collection statistics are provided in Supplementary Table 3.

464 **C.** Morgagni images of SARS-CoV-2 S6P$_{ecto}$ protein only, immediately after COV2-3434 Fab

465 was added to SARS-CoV-2 S6P$_{ecto}$ trimer, incubated for 1, 5, 30 mins or 1 hr and placed on an

466 nsEM grid.

467 **D**. Negative-stain 2D classes of SARS-CoV-2 S6P$_{ecto}$ protein only or COV2-3434 Fab with a

468 monomer of SARS-CoV-2 S6P$_{ecto}$ protein (based on the density surrounding the Fab).

469 **Figure 5. Structural characterization of the trimer-disrupting antibody COV2-3434**.

470 **A.** Residues identified as important for COV2-3434 binding are highlighted as spheres on the S

471 protein structure (green ribbon; PDB 7L2C) F43 (magenta), F175, L176 (cyan), or L226

472 (orange). Residues critical for COV2-3434 binding were identified from binding screens of an

473 alanine scanning mutagenesis library of NTD.

474 **B**. MAb binding values for COV2-3434, COV2-3439, and control anti-NTD mAb COV2-2305

475 are shown at SARS-CoV-2 S protein clones identified as critical for MAb binding. MAb

476 reactivities for each mutant are expressed as percent of binding to wild-type S protein, with

477 ranges (half of the maximum minus minimum values). Two replicate values were obtained for

478 each experiment.

479 **C**. Negative-stain EM of SARS-CoV-2 rNTD protein in complex with COV2-3439 and COV2-

480 3434 Fabs. Top view and side view of superimposed 3D volume COV2-3434 Fab - COV2-3439

481 Fab - SARS-CoV-2 rNTD complexes as visualized by negative-stain EM aligned to S protein of

482 SARS-CoV-2 in complex with 4A8 (PDB: 7C2L) Data are from a single experiment; detailed

483 collection statistics are provided in Supplementary Table 3.

484 **D.** ELISA binding to SARS-CoV-2 $S6P_{ecto}$ or SARS-CoV-2 S6P-2C was measured by

485 absorbance at 450 nm. The COV2-2130 starting concentration was 200 ng/mL, the COV2-2676

486 and COV2-3434 starting concentrations were 20 µg/mL, and mAbs were titrated two-fold.

487 Calculated EC_{50} values are shown on the graph. Error bars indicate standard deviation; data

488 represent at least two independent experiments performed in technical duplicate.

489 **E.** Measurement of serum antibody competition with trimer interface antibody COV2-3434 in

490 individuals before or after SARS-CoV-2 mRNA vaccination. Competition-binding ELISA

24

491 curves for COV2-3434 with human serum from convalescent or vaccinated donors. Competition-

492 binding experiments were performed for each sample in triplicate and repeated in at least 2

493 independent experiments. One representative experiment is shown. For all competition-binding

494 curves, data points indicate the mean and error bars indicate the standard deviation.

495 **Figure 6. Escape virus neutralization and protection in K18 hACE2 transgenic mice by**

496 **trimer-disrupting antibody COV2-3434**.

497 **A.** Neutralization of mAb escape viruses selected by RBD-specific mAbs COV2-2479 (red),

498 COV2-2130 (green), COV2-2094 (magenta) or COV2-2499 (purple) and NTD-specific mAbs

499 COV2-2676 (blue) or COV2-2489 (cyan) and with VSV-S by COV2-3434 or COV2-2196

500 (positive control). Mutations selected by those mAbs are listed with the references. Toward the

501 right, the RTCA curves show neutralization of those escape viruses, The * symbol indicates lack

502 of neutralization in wells with only virus and no antibody.

503 **B.** Eight-week-old male K18-hACE2 transgenic mice were inoculated by the intranasal route

504 with 10^4 FFU of SARS-CoV-2 (WA1/2020 D614G). One day prior to virus inoculation, mice

505 were given a single 200 µg (~10 mg/kg) dose of COV2-3434 or COV2-2196 by intraperitoneal

506 injection. Weight change was monitored daily. Data are from two independent experiments,

507 n=10 per group. **, $p<0.01$; ****, $p<0.0001$. Error bars represent SEM.

508 **C.** At 6 dpi, lungs were collected and assessed for infectious viral burden by plaque assay.

509 Plaque-forming units (PFU)/g is shown. Bars indicate the mean viral load; the dotted line

510 indicates the limit of detection of the assay. Data are from two independent experiments, n=10

511 per group. **, $p<0.01$; ****, $p<0.0001$.

526

527 **DATA AND CODE AVAILABILITY.** All data needed to evaluate the conclusions in the paper

528 are present in the paper or the Supplemental Information. The antibodies in this study are

529 available by Material Transfer Agreement with Vanderbilt University Medical Center.

530

531 **EXPERIMENTAL MODEL AND SUBJECT DETAILS**

532 **Research participants**. We studied the peripheral blood B cells from four individuals with a

533 history of laboratory-confirmed symptomatic SARS-CoV-2 infection. The study was approved

534 by the Institutional Review Board of Vanderbilt University Medical Center and specimens were

535 obtained after written informed consent.

27

536

Cell lines. Vero (ATCC, CCL-81), HEK293 (ATCC, CRL-1573) and HEK293T (ATCC, CRL-3216) cells were maintained at 37°C in 5% CO2 in Dulbecco's minimal essential medium (DMEM) containing 10% (v/v) heat-inactivated fetal bovine serum (FBS), 10 mM HEPES pH 7.3, 1 mM sodium pyruvate, 1× non-essential amino acids and 100 U/mL of penicillin–streptomycin. Vero-furin cells were obtained from T. Pierson (NIAID, NIH) and have been described previously (45) Vero-hACE2-TMPRSS2 cells were a gift of A. Creanga and B. Graham (Vaccine Research Center, NIH). FreeStyle 293F cells (Thermo Fisher Scientific, R79007) were maintained at 37°C in 8% CO2. Expi293F cells (Thermo Fisher Scientific, A1452) were maintained at 37°C in 8% CO2 in Expi293F Expression Medium (Thermo Fisher Scientific, A1435102). ExpiCHO cells (Thermo Fisher Scientific, A29127) were maintained at 37°C in 8% CO2 in ExpiCHO Expression Medium (Thermo Fisher Scientific, A2910002). Mycoplasma testing of Expi293F and ExpiCHO cultures was performed monthly using a PCR-based mycoplasma detection kit (ATCC, 30-1012K).

550

Antigen purification. A variety of recombinant soluble protein antigens were used in the LIBRA-seq experiment and other experimental assays. For the LIBRA-seq experiment, we used the S6Pecto construct. This plasmid encoded residues 1–1,208 of the SARS-CoV-2 S protein with a mutated S1/S2 cleavage site, proline substitutions at positions 817, 892, 899, 942, 986 and 987, and a C-terminal T4-fibritin trimerization motif, an 8x HisTag, and a TwinStrepTag (SARS-CoV-2 spike HP). DNA encoding this construct was transiently transfected with PEI in Expi293F cells and after six days of expression, supernatants were harvested, and protein was

558   affinity-purified over a StrepTrap HP column (Cytiva Life Sciences). Protein was further

559   resolved to homogeneity over a Superose 6 Increase column (GE Life Sciences).

560

561   We generated a plasmid containing a synthesized cDNA encoding a protein designate SARS -

562   CoV-2 S-2P that possessed residues 1–1,208 of the SARS-CoV-2 spike protein as described

563   ((Wrapp et al., 2020)46) with a mutated S1/S2 cleavage site, proline substitutions at amino acid

564   positions 986 and 987, a C-terminal T4-fibritin trimerization motif, an 8x HisTag, and a

565   TwinStrepTag. The plasmids were transiently transfected into FreeStyle 293F cells (Thermo

566   Fisher Scientific) using polyethylenimine. The design of the two-proline (2P) forms of the

567   coronavirus trimer spike antigens results in a prefusion-stabilized conformation that better

568   represents neutralization-sensitive epitopes in comparison to their wild-type forms. Two h after

569   transfection, cells were treated with kifunensine to ensure uniform glycosylation. Transfected

570   supernatants were harvested after 6 days of expression.

571   SARS-CoV-2 S1 (cat. no: 40591-V08B1), SARS-CoV-2 S2 (cat. no: 40590-V08B), SARS-CoV-

572   2 RBD (cat. no: 40592-V05H) and SARS-CoV-2 NTD (cat. no: 40591-V41H-B-20) truncated

573   proteins were purchased (Sino Biological).

574

575   A gene encoding the ectodomain of a pre-fusion conformation-stabilized SARS-CoV-2 S protein

576   ectodomain (S6Pecto) (Hsieh et al., 2020) was synthesized and cloned into a DNA plasmid

577   expression vector for mammalian cells. A similarly designed S protein antigen with two prolines

578   and removal of the furin cleavage site for stabilization of the prefusion form of S (S2Pecto) was

579   reported previously (Wrapp et al., 2020). In brief, this gene includes the ectodomain of SARS-

29

580　CoV-2 (to residue 1,208), a T4 fibritin trimerization domain, an AviTag site-specific

581　biotinylation sequence and a C-terminal 8× His tag. To stabilize the construct in the pre-fusion

582　conformation, we included substitutions F817P, A892P, A899P, A942P, K986P and V987P and

583　mutated the furin cleavage site at residues 682–685 from RRAR to ASVG. The recombinant

584　S6Pecto protein was isolated by metal affinity chromatography on HisTrap Excel columns

585　(Cytiva), and protein preparations were purified further by size-exclusion chromatography on a

586　Superose 6 Increase 10/300 column (Cytiva). The presence of trimeric, pre-fusion conformation

587　S protein was verified by negative-stain electron microscopy (Zost et al., 2020b). For electron

588　microscopy with S protein and Fabs, we expressed a variant of S6Pecto lacking an AviTag but

589　containing a C-terminal Twin-Strep-tag, similar to that described previously (Zost et al., 2020b).

590　Expressed protein was isolated by metal affinity chromatography on HisTrap Excel columns

591　(Cytiva), followed by further purification on a StrepTrap HP column (Cytiva) and size-exclusion

592　chromatography on TSKgel G4000SWXL (TOSOH).

593

594　**Mouse models.** Animal studies were carried out in accordance with the recommendations in the

595　Guide for the Care and Use of Laboratory Animals of the National Institutes of Health. The

596　protocols were approved by the Institutional Animal Care and Use Committee at the Washington

597　University School of Medicine (assurance number A3381–01). Virus inoculations were

598　performed under anesthesia that was induced and maintained with ketamine hydrochloride and

599　xylazine, and all efforts were made to minimize animal suffering. Heterozygous K18-hACE

600　c57BL/6J mice (strain: 2B6.Cg-Tg(K18-ACE2)2Prlmn/J) were obtained from Jackson

601　Laboratory (034860). Eight to nine week-old mice of both sexes were inoculated with 103 PFU

602　of SARS-CoV-2 by an intranasal route.

603

DNA-barcoding of antigens:

604

605   We used oligonucleotides that possess a 15-basepair antigen barcode, a sequence capable of

606 annealing to the template-switch oligonucleotide that is part of the 10X Genomics bead-delivered

607 oligonucleotides and contain truncated TruSeq small RNA read-1 sequences in the following

608 structure: 5'-

609 CCTTGGCACCCGAGAATTCCANNNNNNNNNNNNNNNCCCATATAAGA*A*A-3', where

610 Ns represent the antigen barcode as previously described (Setliff et al., 2019). For each antigen, a

611 unique DNA barcode was directly conjugated to the antigen itself. In particular, 5'amino-

612 oligonucleotides were conjugated directly to each antigen using the SoluLINK Protein-

613 Oligonucleotide Conjugation Kit (TriLink cat. no. S-9011) according to manufacturer's

614 instructions. Briefly, the oligonucleotide and protein were desalted, and then the amino-oligo

615 was modified with the 4FB crosslinker, and the biotinylated antigen protein was modified with

616 S-HyNic. Then, the 4FB-oligo and the HyNic-antigen were mixed. This action causes a stable

617 bond to form between the protein and the oligonucleotide. The concentration of the antigen-oligo

618 conjugates was determined by a BCA assay, and the HyNic molar substitution ratio of the

619 antigen-oligo conjugates was analyzed using a NanoDrop instrument according to the SoluLINK

620 protocol guidelines. Chromatography separation on an AKTA FPLC instrument was used to

621 remove excess oligonucleotide from the protein-oligo conjugates, which were also verified using

622 SDS-PAGE with a silver stain. Antigen-oligo conjugates also were used in flow cytometry

623 titration experiments.

624

625   **METHOD DETAILS**

626   **Antigen-specific B cell sorting.** Cells were stained and mixed with DNA-barcoded antigens and

627   other antibodies, and then sorted using fluorescence activated cell sorting (FACS). First, cells

628   were counted, and viability was assessed using Trypan Blue. Then, cells were washed three

629   times with DPBS supplemented with 0.1% bovine serum albumin (BSA). Cells were

630   resuspended in DPBS-BSA and stained with cell markers including viability dye (Ghost Red

631   780), CD14-APC-Cy7, CD3-FITC, CD19-BV711, and IgG-PE-Cy5. Additionally, antigen-oligo

632   conjugates were added to the stain. After staining in the dark for 30 min at room temperature,

633   cells were washed three times with DPBS-BSA at 300 x g for five min. Cells then were

634   incubated for 15 min at room temperature with Streptavidin-PE to label cells with bound antigen.

635   Cells were washed three times with DPBS-BSA, resuspended in DPBS, and sorted by FACS.

636   Antigen-positive cells were bulk sorted and delivered to the Vanderbilt Technologies for

637   Advanced Genomics (VANTAGE) sequencing core laboratory at an appropriate target

638   concentration for 10X Genomics library preparation and subsequent sequence analysis. FACS

639   data were analyzed using FlowJo™ Software (Mac) version 10.6 (Becton, Dickinson).

640

641   **Sample preparation, library preparation, and sequencing.** Single-cell suspensions were

642   loaded onto a Chromium Controller microfluidics device (10X Genomics) and processed using

643   the B-cell Single Cell V(D)J solution according to manufacturer's suggestions for a target

644   capture of 10,000 B cells per 1/8 10X cassette, with minor modifications to intercept, amplify

645   and purify the antigen barcode libraries as previously described (Setliff et al., 2019).

646

647 **Sequence processing and bioinformatic analysis.** We used our previously described pipeline to

648 use paired-end FASTQ files of oligo libraries as input, process and annotate reads for cell

649 barcode, UMI, and antigen barcode, and generate a cell barcode - antigen barcode UMI count

650 matrix ((Setliff et al., 2019; Shiakolas et al., 2021). BCR contigs were processed using Cell

651 Ranger software (10X Genomics) using GRCh38 as reference. Antigen barcode libraries were

652 also processed using Cell Ranger. The overlapping cell barcodes between the two libraries were

653 used as the basis of the subsequent analysis. We removed cell barcodes that had only non-

654 functional heavy chain sequences and cells with multiple functional heavy chain sequences

655 and/or multiple functional light chain sequences, reasoning that these may be multiplets.

656 Additionally, we aligned the BCR contigs (filtered_contigs.fasta file output by Cell Ranger, 10X

657 Genomics) to IMGT reference genes using HighV-Quest (Alamyar et al., 2012). The output of

658 HighV-Quest was parsed using ChangeO (Gupta et al., 2015) and merged with an antigen

659 barcode UMI count matrix. Finally, we determined the LIBRA-seq score for each antigen in the

660 library for every cell as previously described (Setliff et al., 2019).

661

662 **High-throughput antibody expression.** For high-throughput production of recombinant

663 antibodies, approaches were used that are designated as microscale. For antibody expression,

664 microscale transfections were performed (~1 mL per antibody) of Chinese hamster ovary

665 (CHO) cell cultures using the Gibco ExpiCHO Expression System and a protocol for deep 96-

666 well blocks (Thermo Fisher Scientific). In brief, synthesized antibody-encoding DNA (~2 µg

667 per transfection) was added to OptiPro serum free medium (OptiPro SFM), incubated with

668 ExpiFectamine CHO Reagent and added to 800 µL of ExpiCHO cell cultures into 96-deep-well

669 blocks using a ViaFlo 384 liquid handler (Integra Biosciences). The plates were incubated on an

670   orbital shaker at 1,000 r.p.m. with an orbital diameter of 3 mm at 37°C in 8% CO2. The day

671   after transfection, ExpiFectamine CHO Enhancer and ExpiCHO Feed reagents (Thermo Fisher

672   Scientific) were added to the cells, followed by 4 d incubation for a total of 5 d at 37°C in 8%

673   CO2. Culture supernatants were collected after centrifuging the blocks at 450 x g for 5 min and

674   were stored at 4°C until use. For high-throughput microscale antibody purification, fritted deep-

675   well plates were used containing 25 μL of settled protein G resin (GE Healthcare Life Sciences)

676   per well. Clarified culture supernatants were incubated with protein G resin for antibody

677   capturing, washed with PBS using a 96-well plate manifold base (Qiagen) connected to the

678   vacuum and eluted into 96-well PCR plates using 86 μL of 0.1 M glycine-HCL buffer

679   pH 2.7. After neutralization with 14 μL of 1 M Tris-HCl pH 8.0, purified antibodies were

680   buffer-exchanged into PBS using Zeba Spin Desalting Plates (Thermo Fisher Scientific) and

681   stored at 4°C until use.

682

683   **MAb production and purification.** cDNAs encoding mAbs of interest were synthesized (Twist

684   Bioscience) and cloned into an IgG1 monocistronic expression vector (designated as pTwist-

685   mCis_G1) or Fab expression vector (designated as pTwist-mCis_FAB) and used for production

686   in mammalian cell culture. This vector contains an enhanced 2A sequence and GSG linker that

687   allows for the simultaneous expression of mAb heavy and light chain genes from a single

688   construct upon transfection (Chng et al., 2015). For antibody production, we performed

689   transfection of ExpiCHO cell cultures using the Gibco ExpiCHO Expression System as

690   described by the vendor. IgG molecules were purified from culture supernatants using HiTrap

691   MabSelect SuRe (Cytiva) on a 24-column parallel protein chromatography system (Protein

692   BioSolutions).

693

694   Fab proteins were purified using CaptureSelect column (Thermo Fisher Scientific). Purified

695   antibodies were buffer-exchanged into PBS, concentrated using Amicon Ultra-4 50-kDa (IgG) or

696   30 kDa (Fab) centrifugal filter units (Millipore Sigma) and stored at 4°C until use. F(ab¢)2

697   fragments were generated after cleavage of IgG with IdeS protease (Promega) and then purified

698   using TALON metal affinity resin (Takara) to remove the enzyme and protein A agarose (Pierce)

699   to remove the Fc fragment. Purified mAbs were tested routinely for endotoxin levels and found

700   to be less than 30 EU per mg IgG. Endotoxin testing was performed using the PTS201F cartridge

701   (Charles River), with a sensitivity range from 10 to 0.1 EU per mL, and an Endosafe Nexgen-

702   MCS instrument (Charles River).

703

704   **ELISA binding assays.** Wells of 96-well microtiter plates were coated with purified

705   recombinant SARS-CoV-2 S6Pecto, SARS-CoV-2 S NTD, or SARS-CoV-2 RBS protein at

706   4□°C overnight. Plates were blocked with 2% non-fat dry milk and 2% normal goat serum in

707   Dulbecco's phosphate-buffered saline (DPBS) containing 0.05% Tween-20 (DPBS-T) for 1 h.

708   The bound antibodies were detected using goat anti-human IgG conjugated with horseradish

709   peroxidase (HRP) (Southern Biotech, cat. 2040-05, lot B3919-XD29, 1:5,000 dilution) and a

710   3,3′,5,5′-tetramethylbenzidine (TMB) substrate (Thermo Fisher Scientific). Color development

711   was monitored, 1 M HCl was added to stop the reaction, and the absorbance was measured at

712   450 nm using a spectrophotometer (Biotek). For dose–response assays, serial dilutions of

713   purified mAbs were applied to the wells in triplicate, and antibody binding was detected as

714   detailed above. Half maximal effective concentration (EC_{50}) values for binding were determined

715   using Prism v.8.0 software (GraphPad) after log transformation of the mAb concentration using

716   sigmoidal dose–response nonlinear regression analysis.

717

718   **Cell-surface antigen-display assay.** Vero cell monolayers were monitored until 80% confluent

719   and then inoculated with VSV-SARS-CoV-2 virus (Wa1/2020 strain) (designated here as VSV-

720   S) at an MOI of 0.5 in culture medium (DMEM with 2% FBS). For a T-225 flask, 10 mL of

721   diluted VSV-S virus was added to the monolayer, then incubated for 40 min. During the

722   incubation, the flask was gently rocked back and forth every 10 min to ensure even infection.

723   Following, the incubation the flask volume was topped off to 30 mL with 2% FBS containing

724   DMEM and incubated for 14 h. Cells were monitored for CPE under a microscope, were

725   trypsinized and washed in FACS buffer. 100,000 infected cells were seeded per well to stain

726   with respective antibodies. All antibody was diluted to 10 µg/mL in FACS buffer, and then

727   serially diluted 3-fold 7 times to stain for antibodies that react to cell-surface-displayed S protein.

728   Infected cells then were resuspended in 50 µL of diluted antibody. Antibody binding was

729   detected with anti-IgG Alexa-Fluor-647-labelled secondary antibodies. Cells were analyzed on

730   an iQue cytometer for staining first by gating to identify infected cells as indicated by GFP-

731   positive cells, and then gated for secondary antibody binding.

732

733   **Focus reduction neutralization test (FRNT).** Serial dilutions of serum/plasma were incubated

734   with 102 FFU of SARS-CoV-2 for 1 h at 37°C. The antibody-virus complexes were added to

735   Vero E6 cell-culture monolayers in 96-well plates for 1 h at 37°C. Cells then were overlaid with

736   1% (w/v) methylcellulose in minimum essential medium (MEM) supplemented to contain 2%

737 heat-inactivated FBS. Plates were fixed 30 h later by removing overlays and fixed with 4%

738 paraformaldehyde (PFA) in PBS for 20 min at room temperature. The plates were incubated

739 sequentially with 1 μg/mL of rCR3022 anti-S antibody or a murine anti-SARS-CoV-2 mAb,

740 SARS2-16 (hybridoma supernatant diluted 1:6,000 to a final concentration of ~20 ng/mL) and

741 then HRP-conjugated goat anti-human IgG (Sigma-Aldrich, A6029) in PBS supplemented with

742 0.1% (w/v) saponin (Sigma) and 0.1% BSA. SARS-CoV-2-infected cell foci were visualized

743 using TrueBlue peroxidase substrate (KPL) and quantitated on an ImmunoSpot 5.0.37 Macro

744 Analyzer (Cellular Technologies). Half maximal inhibitory concentration (IC_{50}) values were

745 determined by nonlinear regression analysis (with a variable slope) using Prism software.

746

747 **High-throughput real-time cell analysis (RTCA) neutralization assay.** To screen for

748 neutralizing activity in the panel of recombinantly expressed mAbs, we used a high-throughput

749 and quantitative RTCA assay and xCelligence RTCA HT Analyzer (ACEA Biosciences) that

750 assesses kinetic changes in cell physiology, including virus-induced cytopathic effect (CPE).

751 Twenty μL of cell culture medium (DMEM supplemented with 2% FBS) was added to each well

752 of a 384-well E-plate using a ViaFlo384 liquid handler (Integra Biosciences) to obtain

753 background reading. Six thousand (6,000) Vero-furin cells in 20 μL of cell culture medium

754 were seeded per well, and the plate was placed on the analyzer. Sensograms were visualized

755 using RTCA HT software version 1.0.1 (ACEA Biosciences). For a screening neutralization

756 assay, equal amounts of virus were mixed with micro-scale purified antibodies in a total volume

757 of 40 μL using DMEM supplemented with 2% FBS as a diluent and incubated for 1 h at 37°C

758 in 5% CO2. At ~17–20 h after seeding the cells, the virus–mAb mixtures were added to the

759 cells in 384-well E-plates. Wells containing virus only (in the absence of mAb) and wells

760   containing only Vero cells in medium were included as controls. Plates were measured every 8–

761   12 h for 48–72 h to assess virus neutralization. Micro-scale antibodies were assessed in four 5-

762   fold dilutions (starting from a 1:20 sample dilution), and their concentrations were not

763   normalized. In some experiments, mAbs were tested in triplicate using a single (1:20) dilution.

764   Neutralization was calculated as the percent of maximal cell index in control wells without virus

765   minus cell index in control (virus-only) wells that exhibited maximal CPE at 40 to 48 h after

766   applying virus–antibody mixture to the cells. A mAb was classified as fully neutralizing if it

767   completely inhibited SARS-CoV-2-induced CPE at the highest tested concentration, while a

768   mAb was classified as partially neutralizing if it delayed but did not fully prevent CPE at the

769   highest tested concentration.

770

771   **Conventional throughput neutralization assay.** To determine neutralizing activity of

772   serum/plasma and IgG, we used real-time cell analysis (RTCA) assay on an xCELLigence

773   RTCA MP Analyzer (ACEA Biosciences Inc.) that measures virus-induced cytopathic effect

774   (CPE) (Gilchuk et al., 2020; Zost et al., 2020b). Briefly, 50 μL of cell culture medium (DMEM

775   supplemented with 2% FBS) was added to each well of a 96-well E-plate using a ViaFlo384

776   liquid handler (Integra Biosciences) to obtain background reading. A suspension of 18,000 Vero-

777   E6 cells in 50 μL of cell culture medium was seeded in each well, and the plate was placed on

778   the analyzer. Measurements were taken automatically every 15 min, and the sensograms were

779   visualized using RTCA software version 2.1.0 (ACEA Biosciences Inc). VSV-S (0.01 MOI,

780   ~120 PFU per well) was mixed 1:1 with a dilution of serum/plasma or mAb in a total volume of

781   100 μL using DMEM supplemented with 2% FBS as a diluent and incubated for 1 h at 37°C in

782   5% CO_2. At 16 h after seeding the cells, the virus-mAb mixtures were added in replicates to the

783   cells in 96-well E-plates. For the biliverdin assay, biliverdin was added to the virus at a final

784   concentration of 25 μM before addition to the antibody; similarly, polysorbate-80 was added to

785   the virus at 0.02% before addition to the antibody. Triplicate wells containing virus only

786   (maximal CPE in the absence of mAb) and wells containing only Vero cells in medium (no-CPE

787   wells) were included as controls. Plates were measured continuously (every 15 min) for 48 h to

788   assess virus neutralization. Normalized cellular index (CI) values at the endpoint (48 h after

789   incubation with the virus) were determined using the RTCA software version 2.1.0 (ACEA

790   Biosciences Inc.). Results are expressed as percent neutralization in a presence of respective

791   mAb relative to control wells with no CPE minus CI values from control wells with maximum

792   CPE. RTCA IC50 values were determined by nonlinear regression analysis using Prism

793   software.

794

795   Electron microscopy sample and grid preparation, imaging and processing of S6Pecto–Fab

796   complexes. For electron microscopy imaging of spike protein and Fabs, we expressed a variant

797   of S6Pecto containing a C-terminal Twin-Strep-tag, similar to that described previously (Zost et

798   al., 2020b). Expressed protein was incubate with BioLock (IBA Lifesciences) and then isolated

799   by Strep affinity chromatography on StrepTrap HP columns (GE Healthcare). Fabs were

800   expressed as a recombinant Fab and purify with affinity column. For screening and imaging of

801   negatively-stained SARS-CoV-2 S6Pecto protein in complex with human Fabs, the proteins were

802   incubated at a Fab:spike molar ratio of 4:1 for about 1 hour at ambient temperature or overnight

803   at 4°C, and approximately 3 μL of the sample at concentrations of about 10 to 15 μg/mL was

804   applied to a glow-discharged grid with continuous carbon film on 400 square mesh copper

805   electron microscopy grids (Electron Microscopy Sciences). The grids were stained with 0.75%

806   uranyl formate (Ohi et al., 2004). Images were recorded on a Gatan US4000 4k×4k CCD camera

807   using an FEI TF20 (TFS) transmission electron microscope operated at 200 keV and control with

808   Serial EM (Mastronarde, 2005). All images were taken at 50,000× magnification with a pixel

809   size of 2.18 Å per pixel in low-dose mode at a defocus of 1.5–1.8 μm. The total dose for the

810   micrographs was around 30e–per Å2. Image processing was performed using the cryoSPARC

811   (Punjani et al., 2017) software package. Images were imported, CTF-estimated and particles

812   were picked. The particles were extracted with a box size of 256 pixels and binned to 128 pixels

813   (pixel size of 4.36 A/pix) and 2D class averages were performed (see also Supplementary Table

814   3 for detailed). For time point of the complex with Fab Cov2-3434, SARS-CoV-2 S6Pecto

815   protein and the Fab was mixed at ambient temperature and samples of ~3 μL were pulled at the

816   time points and applied to the grid and stained.

817

818   **Serum antibody competition binding ELISAs with biotinylated reference mAbs.** mAb

819   COV2-3434 was biotinylated using NHS-PEG4-biotin (Thermo Fisher Scientific, cat# A39259)

820   according to manufacturer protocol. Following biotinylation, biotinylated COV2-3434 was

821   titrated in ELISA to verify specific binding and verify if EC50 was similar to the un-biotinylated

822   antibody. Serum samples for use in competition ELISA were heat inactivated by incubation at

823   55°C for 1 hr. ELISAs were performed using 384-well plates that were coated overnight at 1

824   μg/mL with S6Pecto containing a C-terminal Twin-Strep-tag, similar to that described

825   previously (Zost et al., 2020b). The following day, plates were washed three times with PBS-T

826   and blocked with 2% bovine serum albumin (BSA) in PBS containing 0.05% Tween-20

827   (blocking buffer). Plates were washed three times with PBS-T and two-fold serial dilutions of

828   donor serum (1:10 initial dilution) or control mAb (20,000 ng/mL initial dilution) in blocking

829 buffer were added to each plate (total volume 25 µL/well) and incubated at RT for 1 hr. After

830 incubation, 5 µL of biotinylated COV2-3434 (20 µg/mL) in blocking buffer were added directly

831 to the wells containing the serial dilutions of competing serum or COV2-3434 mAb. The

832 concentration of biotinylated mAb was calculated to be at approximately the EC90 of the mAb

833 after addition to an equal volume of competing serum or mAb in the plate. Plates were incubated

834 for 30 min at RT and then washed three times with PBS-T. After this wash, HRP-conjugated

835 avidin (Sigma Aldrich, 1:3,500 dilution) in blocking buffer was added and plates were incubated

836 for 1 h. After incubation, plates were washed three times with PBS-T and 25 µL of a 3,3′,5,5′-

837 tetramethylbenzidine (TMB) substrate (Thermo Fisher Scientific) was added to each well. After

838 sufficient development, the reaction was quenched by addition of 25 µL 1 M HCl and the optical

839 density values were measured at 450 nm wavelength on a BioTek plate reader. For each plate,

840 background signal (signal from wells that were not coated with antigen) was subtracted and

841 values were normalized to no-competition controls (signal from wells that had no competing

842 serum or mAb) Four-parameter dose-response/inhibition curves were fit to the normalized data

843 using Prism software (GraphPad) v8.1.1. Each dilution of serum or mAb was performed in

844 triplicate and each experiment was conducted at least twice independently.

845

846 **Protection against SARS-CoV-2 in mice.** Animal studies were carried out in accordance with

847 the recommendations in the Guide for the Care and Use of Laboratory Animals of the National

848 Institutes of Health. The protocols were approved by the Institutional Animal Care and Use

849 Committee at the Washington University School of Medicine (Assurance number A3381-01).

850 Virus inoculations were performed under anesthesia that was induced and maintained with

851 ketamine hydrochloride and xylazine, and all efforts were made to minimize animal suffering.

852

853   Female heterozygous K18-hACE C57BL/6J mice were housed in groups of up to 5 mice per

854   cage at 18 to 24°C ambient temperatures and 40 to 60% humidity. Mice were fed a 20% protein

855   diet (PicoLab 5053, Purina) and maintained on a 12-h light–dark cycle (06:00 to 18:00). Food

856   and water were available ad libitum. Mice (8 to 9 weeks old) were inoculated with 1×10^4 focus

857   forming units of SARS-CoV-2 (viral titer was determined on Vero-TMPRSS2-ACE2 cells) via

858   the intranasal route. Anti-SARS-CoV-2 human mAbs or isotype control mAbs were administered

859   24 h before (prophylaxis) SARS-CoV-2 inoculation. Weights and lethality were monitored daily

860   for up to 6 days after inoculation and mice were euthanized at 6 dpi and tissues were collected.

861

862   **Epitope mapping of antibodies by alanine-scanning mutagenesis.** Epitope mapping was

863   performed essentially as described previously (Davidson and Doranz, 2014) using a SARS-CoV-

864   2 (strain Wuhan-Hu-1) spike protein NTD shotgun mutagenesis mutation library, made using a

865   full-length expression construct for spike protein, where 215 residues of the NTD (between spike

866   residues 9 and 310) were mutated individually to alanine, and alanine residues to serine.

867   Mutations were confirmed by DNA sequencing, and clones arrayed in a 384-well plate, one

868   mutant per well. Binding of mAbs to each mutant clone in the alanine scanning library was

869   determined, in duplicate, by high-throughput flow cytometry. A plasmid encoding cDNA for

870   each spike protein mutant was transfected into HEK-293T cells and allowed to express for 22 h.

871   Cells were fixed in 4% (v/v) paraformaldehyde (Electron Microscopy Sciences), and

872   permeabilized with 0.1% (w/v) saponin (Sigma-Aldrich) in PBS plus calcium and magnesium

873   (PBS++) before incubation with mAbs diluted in PBS++, 10% normal goat serum (Sigma), and

874   0.1% saponin. MAb screening concentrations were determined using an independent

875 immunofluorescence titration curve against cells expressing wild-type S protein to ensure that

876 signals were within the linear range of detection. Antibodies were detected using 3.75 μg/mL of

877 Alexa-Fluor-488-conjugated secondary antibodies (Jackson ImmunoResearch Laboratories) in

878 10% normal goat serum with 0.1% saponin. Cells were washed three times with PBS++/0.1%

879 saponin followed by two washes in PBS, and mean cellular fluorescence was detected using a

880 high-throughput Intellicyte iQue flow cytometer (Sartorius). Antibody reactivity against each

881 mutant S protein clone was calculated relative to wild-type S protein reactivity by subtracting the

882 signal from mock-transfected controls and normalizing to the signal from wild-type S-transfected

883 controls. Mutations within clones were identified as critical to the mAb epitope if they did not

884 support reactivity of the test MAb but supported reactivity of other SARS-CoV-2 antibodies.

885 This counter-screen strategy facilitates the exclusion of S protein mutants that are locally

886 misfolded or have an expression defect.

887

888 **Measurement of viral burden.** Plaque assays were performed as described previously (Case et

889 al., 2020; Hassan et al., 2020) on Vero+TMPRSS2+hACE2 cells. Briefly, lung homogenates

890 were serially diluted and added to Vero+TMPRSS2+hACE2 cell monolayers in 12-well plates.

891 Plates were incubated at 37 °C for 1 h and then overlaid with 1% (w/v) methylcellulose in

892 MEM supplemented with 2% FBS. Plates were incubated at 37 °C for 72 h and were then fixed

893 with 4% PFA for 20 min. Plaques were visualized by staining with 0.05% crystal violet in 20%

894 methanol.

895

896 **Quantification and statistical analysis.** Mean ± S.E.M. or mean ± S.D. were determined for

897 continuous variables as noted. Technical and biological replicates are described in the figure

898 legends. For analysis of mouse studies, the comparison of weight-change curves was performed

899 using a one-way ANOVA with Dunnett's post hoc test of the area under the curve for days 3-6

900 post-infection, using Prism v.9.0 (GraphPad). Infectious viral loads were compared by a one-way

901 ANOVA with Dunnett's multiple comparisons test using Prism v.9.0 (GraphPad).

902 **Figure S1. Divergence from inferred germline gene sequences, related to Figure 2**

903 A. The number of mutations of each mAb relative to the inferred germline variable gene was

904 counted for each clone. These numbers then were transformed into percent values and plotted as

905 violin plots. For the heavy chain, values range from 80.4 to 100, with a median of 96.6, a 25th

906 quartile of 94.6 and a 75th quartile of 97.6. For the light chain, values range from 88.1 to 100,

907 with a median of 97.9, a 25th quartile of 96.5 and a 75th quartile of 98.9.

908 B. Bar graph showing IGHV gene usage by 102 clones expressed Y-axis represents number of

909 times same IGHV appeared and on x-axis is the IGHV gene identified.

910 **Figure S2. Gating strategy for cell-surface antigen-display experiment, related to Figure 3**

911 A. The first gate is for all cells, the second gate is for infected cells, and the third gate is for

912 antibody binding to infected cells.

913 B. Overlay of histograms infected cells in light grey on uninfected cells in dark grey gated for

914 Alexa Fluor 647 staining.

915 **Figure S3. Phylogenetic tree obtained after aligning multiple sequence of the heavy chain of**

916 **IGHV1-24 genes, related to Figure 3** identified in this study (red) with IGHV 1-24 genes

44

917   available from sequences 1) deposited in public databases shown in cyan color, 2) from

918   vaccinated individuals shown in purple, or 3) from infected individuals shown in orange.

919   **Figure S4. Competition ELISA of mAbs, related to Figure 4**

920   Competition ELISA of mAbs with previously mapped antibodies COV2-2130, COV2-2196,

921   COV2-2676, COV2-2489, r4A8 or rCR3022. Unlabeled antibodies applied to antigen first are

922   indicated on the left, while biotinylated antibodies that were added to antigen-coated wells

923   second are listed across the top. The number in each box represents the percent competition

924   binding of the biotinylated antibody in the presence of the indicated competing antibody. Heat

925   map colors range from dark grey (100% blocking of the biotinylated antibody) to white (0% or

926   no blocking of the biotinylated antibody).

927   **Figure S5. Epitope identification and characterization of COV2-3439, related to Figure 4**

928   Residues critical for COV2-3439 binding, identified by screening COV2-3439 on an NTD

929   alanine-scan mutagenesis library, are shown in red spheres on the NTD (PDB 7L2C).

930   **Figure S6. Structural characterization of COV2-3434, related to Figure 5**

931   Steric clash of COV2-3434 Fab (green) with SARS-CoV2- S monomer (cyan) in open

932   conformation when modeled double Fab (COV2-3434 Fab (green) COV2-3439 Fab (magenta) +

933   rNTD (blue) complex on to SARS-CoV2- S monomer (cyan) in open conformation.

934   **Figure S7. Neutralization of VSV-S by COV2-3434 related to Figure 5**

935   A. Neutralization of VSV-S by COV2-3434 was measured in the absence or presence of 0.02%

936   polysorbate-80 in Vero-CCL81 cells.

937   B. Neutralization of VSV-S by COV2-3434 was measured in the absence or presence of 25 μM

938   biliverdin in Vero-CCL81 cells.

939   **Figure S8. Protection in K18 hACE2 transgenic mice by trimer-disrupting antibody COV2-**

940   **3434, related to Figure 6.**

941   Eight-week-old female K18-hACE2 transgenic mice were inoculated by the intranasal route with

942   104 FFU of SARS-CoV-2 (WA1/2020 D614G). One day prior to virus inoculation, mice were

943   given a single 1 mg dose of COV2-3434, COV2-2196, or isotype control mAb by intraperitoneal

944   injection. Data are from two independent experiments, n=7 (isotype) or 8 (all other groups).

945   A. Weight was monitored daily. Two-way ANOVA with Dunnett's post-test with comparison to

946   control mAb: **, $p<0.001$; *, $p<0.05$; ns, not significant.

947   B. At 6 dpi, tissues were collected, and viral RNA levels in indicated tissues were determined

948   (line indicates median). One-way ANOVA with Dunnett's post-test: ****, $p<0.0001$; *$p<0.05$;

949   ns, not significant. The dotted line represents the limit of detection (LOD) of the assay.
