Short title: Candidalysin activates epithelial cells via EGFR adaptors

Keywords

Candida, candidalysin, epithelial cells, epidermal growth factor receptor (EGFR), adaptor protein

Abbreviations

AKT/PKB, Protein Kinase B; c-CBL, Casitas B-Lineage Lymphoma; ECE1, Extent of Cell Elongation; ERK, Extracellular Signal-Regulated Kinase; EGFR, Epidermal Growth Factor Receptor; GAB1, Grb2-associated-binding Protein 1; GRB2, Growth Factor Receptor-Bound Protein 2; MAPK, Mitogen-Activated Protein Kinase; MMPs, Matrix Metalloproteinases; OEC, oral epithelial cells; OPC, Oropharyngeal Candidiasis; SAPK/JNK, Stress-activated protein kinases/Jun amino-terminal kinases; SHC, Src Homology 2 And Collagen Protein; SHP2, SH2 Containing Protein Tyrosine Phosphatase-2

Abstract

Candida albicans (*C. albicans*) is a dimorphic human fungal pathogen that can cause severe oropharyngeal candidiasis (OPC, oral thrush) in susceptible hosts. During invasive infection, *C. albicans* hyphae invade oral epithelial cells (OECs) and secrete candidalysin, a pore-forming cytolytic peptide that is required for fungal pathogenesis at mucosal surfaces. Candidalysin induces cell damage and activates multiple MAPK-based innate signaling events that collectively drive the production of downstream inflammatory mediators. The activities of candidalysin are also dependent on the epidermal growth factor receptor (EGFR), but how these signals are integrated is undefined. Here, we identified five essential adaptor proteins as key mediators of the epithelial response to *C. albicans* infection on cultured OECs, including growth factor receptor bound protein 2 (Grb2), Grb2-associated-binding protein 1 (Gab1), Src homology and collagen (Shc), SH2 containing protein tyrosine phosphatase-2 (Shp2) and casitas B-lineage lymphoma (c-Cbl). All these signaling effectors were inducibly phosphorylated in response to *C. albicans*, in a candidalysin-dependent mechanism but additionally required EGFR phosphorylation, matrix metalloproteinases (MMPs) and cellular calcium flux. Of these, Gab1, Grb2 and Shp2 were the dominant drivers of ERK1/2 signaling and production of downstream cytokines. Together, these results identify the key adaptor proteins that drive EGFR signaling mechanisms, which determine oral epithelial responses to *C. albicans.*

Introduction

Fungal infections are highly under-appreciated contributors of morbidity and mortality in humans, but to date there are no vaccines to any pathogenic fungi (1). *Candida* species are a dominant cause of both superficial and life-threatening fungal infections in humans, with *Candida albicans* being the most prevalent. Though normally a benign member of the oral, vaginal and gut commensal microbiota, disturbances caused by environmental cues or a compromised immune system result in overgrowth of *C. albicans,* leading to superficial infections of the mucous membranes, in particularly the oral mucosa, that can significantly lower quality of life and affect millions of individuals annually (2, 3).

An essential feature of *C. albicans* pathogenesis is the formation of hyphae, which cause physical damage to the mucosal epithelium, thereby inducing expression and secretion of innate immune factors such as antimicrobial peptides, alarmins and pro-inflammatory cytokines and chemokiens (4). During infection, *C. albicans* hyphae secrete candidalysin, a cytolytic peptide that is critical for pathogenesis at mucosal surfaces (5). Candidalysin is encoded by *ECE1*, which is highly expressed in hyphae, though not required for filamentation. Candidalysin is generated by processing of its parent protein Ece1p by the kexin proeases (6, 7). Candidalysin secretion is triggers epithelial cell damage and activation of a mitogen-activated protein kinase (MAPK)-based signaling pathway that leads to secretion of inflammatory mediators and cell survival signals (8–10). The epidermal growth factor receptor (EGFR) is key for mediating the host immune response against several microbial pathogens (11), including *C. albicans* (12–16). However, the downstream signals that orchestrate epithelial responses to this fungus are still incompletely understood.

EGFR, also known as Her1 or ErbB1, belongs to a family of receptor tyrosine kinases (RTKs) that regulate cell survival, proliferation, apoptosis, differentiation and development (17). Dysregulation of EGFR is also associated with tumorigenesis (18, 19). EGFR autophosphorylation is a proximal event that initiates downstream signaling, resulting in recruitment of various adaptors and ultimately activating downstream signaling cascades including MAPK, phosphatidylinositol 3-kinase/Akt/Protein Kinase B (PI3K/Akt), and signal transducers and activators of transcription (STATs). Multiple microbes are known to exploit EGFR during pathogenesis, using adaptor

activation and phosphorylation to infiltrate host cells and evade the immune system (11, 20, 21). However, a role for these adaptors in driving immunity to microbes has also emerged (22).

In the present study, we sought to elucidate the role of MAPK signaling and EGFR adaptors in the oral epithelial cell (OEC) response to *C. albicans*. We found that growth factor receptor bound protein 2 (Grb2), Grb2-associated-binding protein 1 (Gab1), Src homology and collagen (Shc), SH2 containing protein tyrosine phosphatase-2 (Shp2, also PTPN11) and casitas B-lineage lymphoma (c-Cbl) are all required to mediate an EGFR-dependent response to *C. albicans* via candidalysin. EGFR kinase inhibitors negatively impact this response, which also requires matrix metalloproteinases and cellular calcium flux. Accordingly, we illuminate the underlying mechanisms of how early EGFR-mediated epithelial responses are orchestrated by the novel fungal toxin candidalysin, with implications for defining the host response to the medically important fungus *C. albicans*.

Results

***Candida albicans* activates EGFR-associated adaptors through secreted candidalysin**

In establishment of oropharyngeal candidiasis (OPC, thrush), oral epithelial cells (OECs) respond to the pore-forming toxin candidalysin secreted from *C. albicans* hyphae. Responses require EGFR signals, which lead to the release of antifungal proinflammatory mediators that ultimately coordinate an effective host response (4, 24). However, the underlying mechanisms of the early EGFR molecular events activated in response to *C. albicans* and candidalysin remain incompletely characterized. Accordingly, TR146 buccal epithelial cells were infected with a *C. albicans* (BWP17 + CIp30, parental strain) at a multiplicity of infection (MOI) of 10 for 2 h, a time pointknown to be optimal for EGFR activation (12). Notably, all proteins known to interact with EGFR were inducibly phosphorylated following infection with *C. albicans* including Gab1 (Y659), Grb2 (p-Tyrosine), Shc (Y317), Shp2 (Y580), c-Cbl (Y774) (Fig. 1A).

Since filamentation is required for *C. albicans*-induced epithelial responses (25), we asked whether candidalysin (Clys) was required for adaptor activation. Mutant *C. albicans* strains lacking the candidalysin parent gene *ECE1* (*ece1*Δ/Δ) or with a deletion of the region that encodes candidalysin (*ece1*Δ/Δ+*ECE1*$_{Δ184–279}$) failed to activate Gab1, Grb2, Shc, Shp2 and c-Cbl (Fig. 1A). To determine whether Clys alone could activate this panel of adaptors, TR146 cells were stimulated with candidalysin over a time course of 2 h. We treated cells with a strongly lytic concentration (70 μM) that triggers membrane damage, calcium flux and cytokine release, an intermediate sub-lytic concentration (15 μM) that activates epithelial signal transduction through MAPK, p38/MKP-1 and c-Fos and the production of immune regulatory cytokines, and a non-lytic concentration (3 μM) that induces low level secretion of selected cytokines (Moyes et al., 2016). Phosphorylation of Gab1 at Y659 was detectable within 30 min of exposure to all concentrations of candidalysin, with phosphorylation levels increased strongly in response to higher concentrations of candidalysin (70 or 15 μM) at 2 h post treatment (Fig. 1B). Lower concentrations of candidalysin that do not cause cell lysis (3 μM), also induced pGab1 Y659 at 2 h post treatment. In contrast, treatment with 70 or 15 μM candidalysin induced Grb2 phosphorylation within 30 min, which was sustained until 2 h. Increased phosphorylation levels were only observed in cells stimulated with 3 μM candidalysin following 2 h of treatment.

Phosphorylation of Shc Y317 was detectable within 30 min following treatment with all concentrations of candidalysin, with a dose-dependent response observed at 30 min and 2 h post stimulation. Together, these data suggest that there is differential temporal organisation of adaptors in response to *C. albicans* and candidalysin, which appears to be an early, coordinated event.

Unexpectedly, the kinetics of Shp2 phosphorylation in response to candidalysin differed from Gab1, Grb2 and Shc, as phosphorylation of Shp2 Y580 was detectable only after 2 h of treatment with 70 or 15 µM candidalysin, with negligible changes in phosphorylation observed with 3 µM (Fig. 1B). These data suggests either that Shp2 may play a role in the response against candidalysin when a significant amount of epithelial damage has been induced, or slower kinetics of Shp2 activity in comparison to the other adaptors. Treatment of TR146 cells with 70 or 15 µM candidalysin triggered strong c-Cbl pY774 activation that was sustained at 30 min and 2 h post stimulation (Fig. 1B). Only very modest changes were observed with 3 µM candidalysin. Collectively, these data show that candidalysin can induce phosphorylation of adaptors in TR146 epithelial cells in a time- and dose-dependent manner, with distinct activation profiles for adaptors in response to lytic versus sub-lytic concentrations of candidalysin.

Gab1, Grb2, Shc, Shp2 and c-Cbl activation requires EGFR activation, MMPs and calcium flux

While EGFR and the Ephrin family member, EphA2, play a critical role in mediating the innate epithelial response to candidalysin and *C. albicans* (12, 13), it is unknown whether the activation of corresponding adaptors in response to hyphae relies exclusively on EGFR. To determine whether EGFR drives candidalysin-induced adaptor activation, we analyzed the effects of the EGFR-specific kinase inhibitors on the activation of Gab1, Grb2, Shc, Shp2 and c-Cbl. Treatment of TR146 cells with EGFR inhibitors gefitinib or PD153035 reduced *C. albicans*-induced phosphorylation of Gab1, Grb2, Shc, Shp2 and c-Cbl at 2 h post infection (Fig. 2A). Similarly, inhibition of EGFR abolished phosphorylation of all adaptors in response to candidalysin (70 or 15 µM), indicating that EGFR activation is indeed required for candidalysin-induced adaptor activity (Fig. 2B).

Matrix metalloproteinases (MMPs) are zinc-dependent metallo-endopeptidases that cleave

and release EGF-family pro-ligands, therefore activating EGFR signaling (12). Hence, we next assessed the role of MMPs in the activation of adaptors in response to candidalysin. Pre-treatment of TR146 OECs with the pan-MMP inhibitor Marimastat suppressed phosphorylation of Gab1, Grb2, Shc, Shp2 and c-Cbl upon candidalysin stimulation (Fig. 2C) and infection with *C. albicans* (Supp Fig. S1). Consistent with this, a candidalysin-deficient *C. albicans* strain (*ece1Δ/Δ+ECE1*$_{Δ184–279}$), failed to phosphorylate Gab1, Shc and c-Cbl, though induced very modest levels of phosphorylation for Grb2 and Shp2. Additionally, a blocking anti-EGFR monoclonal antibody (cetuximab) reduced/abolished the phosphorylation of Gab1, Grb2, Shc, Shp2 and c-Cbl in response to candidalysin and *C. albicans* infection (Figure 3), demonstrating that candidalysin-induced activation of adaptors is mediated by MMPs, which in turn mediate ligand-induced activation of EGFR. Previously, calcium influx induced by candidalysin activity was also shown to contribute to EGFR phosphorylation (12). Accordingly, pre-treatment of TR146 cells with the calcium chelator, BAPTA-AM also suppressed candidalysin-induced and *C. albicans*-induced EGFR adaptor activation (Supp. Fig. S2). These data show that candidalysin secreted by *C. albicans* activates EGFR-related adaptors and downstream signaling programs in OECs via a mechanism that requires calcium influx, MMP activity and EGFR ligands.

EGFR adaptors mediate candidalysin-induced MAPK signaling responses but are dispensable for cell survival and damage protection

Candidalysin permeabilizes target cell membranes, resulting in damage (release of lactate dehydrogenase (LDH)) and the activation of PI3K/Akt/mTOR and MAPK (MKP1/c-Fos) signaling pathways (5, 26). Notably, the Akt/mTOR pathway is important in mediating cell survival and protection against damage (26) and the MAPK pathway is required for induction of immune responses (5) during epithelial *C. albicans* infection. Furthermore, Gab1, Grb2 and Shp2 adaptors can mediate the cell survival pathway (27).

To determine whether this panel of EGFR adaptors can modulate these cellular responses, TR146 cells were transfected with siRNAs for Gab1, Grb2, Shc, Shp2 and c-Cbl for 48 h, and stimulated with *C. albicans* or candidalysin for 2 h. LDH release from TR146 cells was unaffected by knockdown of all adaptors following treatment with *C. albicans* (Supp. Fig. S3A) or candidalysin (70 or 15 μM) (Supp. Fig. S3B). Accordingly, the candidalysin null strain

(*ece1Δ/Δ+ECE1$_{Δ184-279}$*) caused no detectable change in epithelial integrity. Assessment of the Akt/mTOR pathway similarly showed no change in phosphorylation upon adaptor knockdown (Supp. Fig. S3C). Thus, these EGFR adaptors do not appear to be required to protect epithelial cells from damage or for cell survival in response to *C. albicans* infection and candidalysin. In contrast, siRNA knockdown of Gab1 and Grb2 had a marked impact on c-Fos protein levels and suppressed phosphorylation of MKP1 in response to *C. albicans* and candidalysin (Fig. 4A, 4B). Knockdown of Shc had only a minor impact on c-Fos and MKP1 activation, and the effects of Shp2 or c-Cbl knockdown were negligible.

To better understand how Gab1 and Grb2 activate c-Fos and MKP1, we next assessed three major branches of the MAPK signaling cascade, ERK1/2, p38 and SAPK/JNK. In response to *C. albicans*, knockdown of Gab1 and Grb2 had a marked effect on ERK1/2 phosphorylation but not p38 or SAPK/JNK (Fig. 4A, 4B). However, in response to candidalysin, while Grb2 knockdown also showed a decrease in pERK1/2, Gab1 knockdown showed a modest increase in ERK1/2, p38 and SAPK/JNK phosphorylation. As expected, a candidalysin-null strain (*ece1Δ/Δ+ECE1$_{Δ184-279}$*) did not trigger MAPK phosphorylation. Thus, Gab1 and Grb2 are required for MAPK activation during *C. albicans* infection, but the Gab1 activation pattern differs when responding to exogenously applied synthetic candidalysin.

Impairing Shp2 via siRNA had no detectable effect on *C. albicans* and candidalysin-induced signals, but Shp2 knockdown was inefficient (60 %, (Supp Fig. S4). Therefore, TR146 cells were pre-treated with the Shp2 inhibitor SHP099 HCL (10 or 5 µM) 1 h prior to infection and assessed for cell damage, MAPK and Akt/mTor pathway activation. Similar to observations with Shp2 siRNA, LDH release and mTOR phosphorylation from TR146 oral epithelial cells was unaffected by Shp2 inhibition (Supp Fig. S5). However, treatment with SHP099 HCL suppressed *C. albicans*- and candidalysin-induced levels of c-Fos and pMKP1 and pERK1/2, though not pSAPK/JNK or pp38 (Fig. 5). Thus, in addition to a key role for Gab1 and Grb2 adaptors, Shc also contributes to ERK1/2 activation in response to *C. albicans* and candidalysin.

Gab1, Grb2 and Shp2 are required for production of inflammatory effectors in response to candidalysin

A characteristic end point of candidalysin activity and EGFR activation is the production of inflammatory cytokines and chemokines. Using siRNA knockdown, we evaluated the role of this panel of EGFR adaptors in driving the production of G-CSF, GM-CSF, IL-6, IL-1α and IL-1β from TR146 cells 24 h after *C. albicans* or candidalysin treatment. Knockdown of Gab1, Grb2 or Shc reduced secretion of GM-CSF, G-CSF and IL-1α in response to *C. albicans* (Fig. 6A, 6B, Supp Fig. 6A) and candidalysin (Supp Fig. 6B, C, E). Notably, only Gab1 or Grb2 knockdown reduced release of IL-1β and IL-6 in response to *C. albicans* (Fig. 6C, 6D), suggesting that distinct pathways dictate adaptor-mediated cytokine responses during fungal signaling on OECs. Interestingly, knockdown of c-Cbl appeared to increase the release of G-CSF in response to *C. albicans*, and GM-CSF and IL-6 in response to candidalysin (Fig. 6A, Supp Fig 6C, 6D), possibly suggesting a negative regulatory role for c-Cbl in immune signaling. The Shp2 inhibitor, SHP099 HCL, impaired G-CSF, GM-CSF, IL-1α and IL-β secretion in response to *C. albicans* treatment (Fig. 6E, Supp Fig. 7A, 7C, 7D). Similarly, Shp2 inhibition significantly reduced G-CSF, GM-CSF and IL-β release in response to candidalysin (Supp Fig. 7E, 7F, 7H). Interestingly, Shp2 inhibition resulted in a significant increase in IL-6 release in response to candidalysin (Fig. 6F). Overall, these data indicate that Gab1, Grb2, Shc and Shp2 adaptors but not c-Cbl play pivotal roles in mediating the innate immune response to fungal infection.

Discussion

The oral epithelium coordinates the early antifungal response to infection through release of cytokines, chemokines and other inflammatory mediators that recruit leukocytes, infiltrating neutrophils and inflammatory monocytes to combat infection. Interactions between epithelial cells and *C. albicans* are critical for host defence mechanisms to mucosal infection. The discovery of the *C. albicans*-derived toxin, candidalysin, was a paradigm shift in understanding how hyphae promote pathogenesis, simultaneously causing target cell damage but also activating innate immune responses that are essential to limit control of this commensal microbe. This discovery led to a myriad of studies revealing how candidalysin activity interfaces with the host immune system and balances commensalism with pathogenicity (6–10, 12, 28–33)

Candidalysin activates the EGFR and MAPK signaling pathways (5, 12), but how these pathways are controlled remained incompletely defined. The EGFR adaptor proteins play a critical role in facilitating signaling between upstream cell surface RTKs, such as EGFR, as well as downstream cellular signaling cascades that are fundamental for a diverse array of cellular processes (34). We show that not only does OEC infection with *C. albicans* activate the Gab1, Grb2, Shc, Shp2 and c-Cbl adaptors, but that this is driven by candidalysin. Furthermore, the distinct temporal activity of these EGFR adaptors suggest they may mediate the early, coordinated response of OECs to ensure appropriate signaling during fungal infection. Notably, no studies have implicated EGFR adaptor activation in response to fungal infection and very few in bacterial infections (20, 21, 35).

In addition to EGFR, Gab1, Grb2, Shc, Shp2 and c-Cbl are essential for signaling responses of RTKs, including EphA2, c-Met and other Her-family members (36–38). The near abolishment of adaptor activation in response to EGFR inhibition confirmed EGFR is a critical receptor for adaptor protein activation and downstream responses to *C. albicans* via candidalysin. Previously, we reported that inhibition of EGFR reduces MAPK signaling and subsequent immune responses during infection (12). Interestingly, our present results show that some, but not all, adaptors orchestrate the downstream mechanisms of epithelial immunity to infection. Recent work has demonstrated that Grb2 is associated with EGFR in response to *C. albicans* infection (39), and sustained activation of both EGFR and EphA2 by candidalysin and the hyphal adhesin, Als3, is

required for proinflammatory responses during *C. albicans* infection (13). However, unlike candidalysin, recombinant Als3 does not activate c-Fos/MKP1 or cytokine responses (40), which are downstream of EGFR signaling, suggesting Als3 does not directly activate these EGFR adaptors. Additionally, it should be noted that a *ALS3*-deficient strain is poor at forming the invasion pocket, which is required to enable efficient delivery and activity of candidalysin (8). Together, these data indicate that Als3 does not directly activate EGFR adaptors, and that its role in driving epithelial signaling and/or immune responses is probably due to its role in facilitating the formation of the invasion pocket to permit efficient secretion of candidalysin, which activates these processes.

Candidalysin induces EGFR activation by activating matrix metalloproteinases (MMPs), which cleave EGFR pro-ligands that subsequently bind EGFR, and inducing calcium influx (5, 12)*. Various MMPs activate EGFR in response to a diverse array of stimuli (41, 42). Additionally, MMP activation and subsequent cleavage and release of EGFR ligands are involved in the activation of EGFR in response to *Helicobacter pylori* and *Clostridium difficile* (43, 44). The role of MMPs in infectious diseases, such as mycobacterial infection and *Paracoccidioides brasiliensis* infection has also been reported (45, 46). We now demonstrate that MMPs mediate antifungal immune responses via EGFR through the adaptors described herein.

Candidalysin is the first pore-forming toxin (PFT) identified in a human fungal pathogen. Like analogous toxins in other organisms, candidalysin causes a rapid influx of intracellular calcium, thought to be a pivotal step in the activation of downstream signaling events (47). Calcium influx triggered by bacterial PFTs is also a key factor in the induction of cellular responses that limit infection and promote survival (48, 49). We found that chelation of calcium reduced the activation of adaptors in response to *C. albicans* and candidalysin. As such, our results demonstrate a role for calcium flux induced by candidalysin in inducing EGFR adaptor activation and epithelial immune responses during *C. albicans* infection.

Candidalysin induces cell stress in OECs, with the release of alarmins, ATP and antimicrobial peptides (AMPs) (16). Shc activation has been associated with a cellular stress response (50) and Shp2 is critical in regulating the stress response to aryl hydrocarbon receptor activation and calcium dynamics in mast cells (51). It is likely that candidalysin induces stress-

associated signals in OECs during *C. albicans* infection, which is mediated through EGFR adaptors.

This work establishes roles for multiple EGFR-related adaptors in the response to candidalysin secreted from *C. albicans*. Notably, four of these proteins, Gab1, Grb2, Shc and Shp2, were required for G-CSF and GM-CSF secretion while Gab1, Grb2 and Shp2, mediated secretion of IL-1α, IL-1β and IL6, demonstrating distinct roles for these adaptor molecules. Very few studies show that Gab1, Grb2 or Shp2 mediate such specific cytokine responses. However, activation of Gab1 and Shp2 are able to transmit signals to the ERK1/2 signaling cascade to activate the cytokine receptor, gp130 (52), and activation of Shc, Grb2 and Shp2 mediate MAPK activation via the G-CSF receptor (53). Both G-CSF and GM-CSF are strong neutrophil recruitment cytokines required for the resolution of *C. albicans* infections (54, 55). The decrease in ERK1/2 phosphorylation in combination with G-CSF and GM-CSF reduction upon Gab1 and Grb2 knockdown suggests that both adaptor proteins control the OEC immune response in response to candidalysin, which may subsequently mediate neutrophil recruitment during *C. albicans* infection *in vivo*.

This is the first reported case of EGFR adaptors in mediating MAPK signaling in the OEC response to fungal infection. Our data show that ERK1/2 is the major pathway activated by the EGFR adaptors, rather than p38 or SAPK/JNK. During OEC infection with *C. albicans,* MAPK signaling is regulated by MKP1, with ERK1/2 mediating a negative feedback loop during *C. albicans* infection to control the immune response (25). These data suggest a dual role for ERK1/2 signaling in response to *C. albicans* and candidalysin; (i) as a mediator of epithelial immune responses and (ii) a regulator of MAPK signaling responses. Interestingly, we only observed a partial reduction in c-Fos total protein when Gab1, Grb2, Shc or Shp2 were knocked down or inhibited during fungal exposure, suggesting that additional as yet unidentified factors can promote cytokine responses against *C. albicans* and candidalysin.

We also found that although siRNA knockdown of Gab1, Grb2 and Shc showed a decrease in cytokine responses, knockdown of c-Cbl showed either no effect or an increase in G-CSF, GM-CSF and IL-1β release in response to *C. albicans* and candidalysin. Additionally, inhibition of Shp2 resulted in an increase in IL-6 secretion, which was most notable in cells treated with candidalysin. This suggests a potential role for c-Cbl and Shp2 as negative regulators of EGFR

signaling and immune induction. While Shp2 expression has been shown to enhance the host immune response to promote bacterial clearance following post-influenza *Staphylococcus aureus* pneumonia (56) and orchestrate macrophage function and regulate host innate immunity against pulmonary bacterial infection (57), there have been no studies that have demonstrated a role for Shp2 in negatively regulation the immune response in OECs to infection. However, Shp2 is known to negatively regulate IL-6 release in macrophages in response to TLR ligands (58), thus, we propose Shp2 may have a similar function to regulate immune responses during OEC fungal infections. The c-Cbl adaptor is important in EGFR trafficking and regulation (59, 60); notably, ubiquitination of EGFR by c-Cbl is implicated in clathrin-independent endocytosis of EGFR and regulation of EGFR signaling (61). Additionally, though the p38 MAPK pathway is pivotal in mediating EGFR endocytosis (62), little is known about the role of p38 in mediating EGFR trafficking in response to infection. It is likely that the complex dynamics of EGFR trafficking during fungal infection plays a significant role in EGFR signaling and the OEC immune response.

In summary, our data indicate that the EGFR-associated adaptors Gab1, Grb2, Shc, Shp2 and c-Cbl play important but distinct roles in regulating epithelial responses in response to candidalysin during *C. albicans* infection (Fig. 7). Though these adaptors have been shown to be key mediators of supporting microbial infection, few studies have also described these adaptor proteins as regulators of the immune response to microbial infections. As such, it is likely that EGFR-associated adaptors act as sentinel regulators of epithelial immune responses during mucosal infections.

Experimental Procedures

Candida albicans strains and Candidalysin

The *C. albicans* strains used were previously described (5) and maintained on yeast extract peptone dextrose (YPD) agar and cultured in YPD at 30°C. For experiments, fungal cells were harvested by centrifugation, washed twice with phosphate buffered saline (PBS) and diluted in appropriate media. Candidalysin (SIIGIIMGILGNIPQVIQIIMSIVKAFKGNK; termed Ece1-III$_{62\text{-}92K}$) was synthesized by Peptide Protein Research Ltd, UK and stored at 3.021 mM (10 mg/mL) in sterile water.

Cell Culture

TR146 human buccal epithelial squamous cell carcinoma cell line (23) was obtained from European Collection of Authenticated Cell Cultures (ECACC) and cultured in Dulbecco's Modified Eagle Medium Nutrient Mixture F-12 HAM (DMEM/F-12)(Gibco) supplemented with 15% foetal bovine serum (FBS)(Gibco) and 1% (v/v) penicillin-streptomycin)(Sigma-Aldrich). Serum-free DMEM/F-12 was used to replace normal growth medium 24 h before and during cell stimulations.

Reagents

Inhibitors were from Santa Cruz Biotechnology (Gefitinib), Selleckchem (PD153035, SHP099HCL) and Tocris Bioscience (Marimastat). The calcium chelator, BAPTA-AM, was purchased from Selleckchem. Inhibitors were reconstituted in DMSO and aliquoted for appropriate freezer temperature storage. Cetuximab was a kind gift from Guy's Hospital Cancer Centre and stored at 4°C. TR146 cells were incubated with inhibitors for 1 h prior to *C. albicans* infection, candidalysin exposure or mock treatment. Antibodies from Cell Signaling Technology: pGab1 Y659 (#12745S), Total Gab1 (#3232S), Total Grb2 (#3972S), pShc Y317 (#2431S), Total Shc (#2432S), pShp2 Y580 (#3703S), Total Shp2 (#3752S), pc-Cbl Y774 (#3555S), Total c-Cbl (#8447S), pMKP1/DUSP1 S359 (#2857S), c-Fos (#2250S), pp44/42 MAPK (ERK1/2) T202/Y204 (#4370S), pp38 MAPK T180/Y182 (#4511S), pSAPK/JNK T183/Y185 (#4668S), pAkt S473 (#4060S), pMTOR S2448 (#5536S) and β-Tubulin (#2146S). Mouse α-actin antibody was from Millipore (#MAB1501), goat anti-mouse IgG (#115-035-062) and goat anti-rabbit IgG

(#111-035-144) horseradish peroxidase (HRP)-conjugated antibodies were from Jackson ImmunoResearch.

RNA Silencing

RNAi primers were from Thermo Fisher Scientific. TR146 cells were transfected with 5 or 10 nM of Gab1 (s5463), Grb2 (s226232), Shc (s12813), Shp2 (s11525), c-Cbl (s2476) (Table S1) or a negative control siRNA (Silencer™ Negative Control No. 2 siRNA) using HiPerfect Transfection Reagent (Qiagen) following the manufacturers' instructions. The extent of knockdown was verified 48 h post-transfection by immunoblotting and for proteins of interest exceeded 80%.

Immunoblotting

TR146 cells were incubated with the indicated fungal strains or treated with candidalysin (70, 15 or 3 μM) for the indicated timepoints. Cells were rinsed with PBS and lysed with RIPA buffer (50 mM Tris-HCl pH 7.5, 150 mM NaCl, 1% (v/v) Triton X-100, 1% (w/v) sodium deoxycholate, 0.1% (w/v) SDS, 20 mM EDTA) containing protease and phosphatase inhibitors (Sigma-Aldrich). Cells were detached with a scraper and lysates incubated on ice for 30 min. 5-10 μg of whole protein extracts were separated on Bolt™ 4 to 12%, Bis-Tris precast gels and transferred to nitrocellulose (Bio-Rad). Membranes were probed for target proteins with specific antibodies against phosphorylated or total proteins and secondary antibodies before being developed using Immobilon chemiluminescent substrate (Millipore) and visualized using the Odyssey Infrared Imaging System (LI-COR).

Immunoprecipitation

TR146 cells were serum starved and infected with *C. albicans* strains at an MOI of 10 or treated with candidalysin (70, 15 or 3 μM) for the indicated times. For inhibitor experiments, cells were pre-treated with inhibitors 1 h prior to infection or stimulation. Cells were washed with PBS and lysed with buffer (25 mM Tris-HCl pH 7.4, 150 mM NaCl, 1% Nonidet P-40 (NP-40), 1 mM EDTA, 5% glycerol) supplemented with protease and phosphatase inhibitors (Sigma-Aldrich) for 30 min. Lysates were centrifuged at 13,000 x g at 4°C for 10 min. Approximately 100 μL of total lysate was used as loading controls and the remaining lysates precleared with 25 μL of protein A/G magnetic beads (Pierce, Thermo Fisher). A mouse phosphotyrosine antibody conjugated to a

magnetic bead (#8095S, Cell Signaling Technology) or control IgG antibody (#5873, Cell Signaling Technology) was added to 250 µg of protein and incubated with rotation overnight at 4°C. Samples were pelleted using a magnetic rack, washed four times with ice cold lysis buffer and protein eluted with 20 µL of 3x SDS buffer containing DTT by heating at 95°C for 5 min. Eluted proteins were separated by SDS-PAGE, and analyzed as described above.

Quantification of cell damage (LDH assay)

A Cytox 96 Non-Radioactive Cytotoxicity Assay Kit (Promega) was used to measure the activity of lactate dehydrogenase (LDH) in cell culture supernatants as described (12, 16). TR146 cells were seeded and stimulated with *C. albicans* or candidalysin. Following each incubation time, exhausted culture medium was collected and analysed for LDH activity as an indicator of *C. albicans* or candidalysin-induced membrane disruption. Assay was conducted according to the manufacturer's instructions and recombinant L-Lactic Dehydrogenase from porcine heart (Sigma-Aldrich) was used to generate a standard curve. Samples were measured for LDH following collection from culture plates.

Cytokine secretion

Cytokine levels in cell culture supernatants were determined as previously described (12). Following infection with *C. albicans* at an MOI of 0.01 or stimulation with candidalysin, conditioned culture medium was collected after 24 h and assessed by Luminex assay (Bio-techne) and a Bioplex-200 machine (Bio-Rad). Bioplex manager 6.1 software was used to determine analyte concentrations.

Statistics

Data were compared by ANOVA with Bonferroni's multiple comparisons test using GraphPad Prism (v. 8) software. *P* values < 0.05 were considered to be statistically significant.

Data Availability

All data on adaptor phosphorylation, inhibition and knockdown assays and cytokine expression are contained within this article.

Supporting Information

This article contains supporting information.

Acknowledgements

We thank Bernard Hube for providing the fungal mutant strains and members of the Centre for Host-Microbiome Interactions at Kings College London and the Division of Rheumatology and Clinical Immunology at the University of Pittsburgh for critical suggestions.

Figure 1. Candidalysin is necessary and sufficient to activate Gab1, Grb2, Shc, Shp2 and c-Cbl adaptors in human oral epithelial cells. (A) Candidalysin activates Gab1, Grb2, Shc, Shp2 and c-Cbl adaptors in human oral epithelial cells (OECs). Immunoblot showing the phosphorylation of Gab1, Grb2, Shc, Shp2 and c-Cbl in response to 2 hour infection of oral epithelial cell with the indicated strains of *C. albicans*. B) Candidalysin is sufficient to activate Gab1, Grb2, Shc, Shp2 and c-Cbl. Immunoblot showing the phosphorylation of Gab1, Grb2, Shc, Shp2 and c-Cbl following stimulation with candidalysin at 30 min and 2 h in oral epithelial cells. Blots are representative of 3 independent experiments.

Figure 2. Candidalysin-induced adaptor activation requires EGFR and MMP activity. Inhibition of EGFR activity suppresses (A) *C. albicans*- and (B) candidalysin (Clys)-induced adaptor activation. Use of either Gefitinib or PD153035 EGFR TK inhibitors suppresses WT *C. albicans*- and candidalysin-induced activation of pGab1, Grb2, Shc, Shp2 and c-Cbl. (C) MMP inhibition suppresses candidalysin-induced adaptor activity. Pre-treatment of TR146 cells with Marimastat (MMP inhibitor, 10 or 1 µM (M10 or M1)) significantly suppressed candidalysin-induced phosphorylation of Gab1, Grb2, Shc, Shp2 and c-Cbl following candidalysin exposure. Protein lysates were taken at 2 h post candidalysin stimulation for western blot analysis. Blots are representative of 2 (Grb2) or 3 (Gab1, Shc, Shp2 and c-Cbl) independent experiments.

Figure 3. EGFR ligand binding is required for *C. albicans* and candidalysin-induced adaptor activation. Pre-treatment of TR146 cells with the anti-EGFR mAb, Cetuximab suppressed phosphorylation of Gab1, Grb2, Shc, Shp2 and c-Cbl following (A) *C. albicans* infection or (B) candidalysin stimulation. Immunoblots are representative of 2 (Grb2) or 3 (Gab1, Shc, Shp2 and c-Cbl) independent experiments.

Figure 4. Gab1, Grb2 and Shc adaptors mediate candidalysin-induced MAPK signalling responses. Knockdown of Gab1, Grb2 or Shc suppresses c-Fos expression, MKP1 and ERK1/2 phosphorylation. Following siRNA mediated knockdown, cells were either infected with the indicated strains (A) or stimulated with candidalysin (B) and protein lysate collected after 2 h for western blot analysis. Lysates were immunoblotted for total c-Fos, phospho-MKP1, phospho-ERK1/2, phospho-p38, phospho-SAPK/JNK or α-actin. Data are representative of 3 independent experiments.

Figure 5. Shp2 mediates candidalysin-induced MAPK signalling responses. Inhibition of Shp2 activity suppresses *C. albicans*- and Candidalysin (Clys)-induced cFos, pMKP1 and ERK1/2 activation. Inhibition of Shp2 activity suppresses G-CSF, GM-CSF, IL-1α and IL-1β secretion. TR146 oral epithelial cells were pre-treated with the Shp2 inhibitor, SHP099HCL for 1 h. Following this, cells were either infected with the indicated strains (A) or stimulated with candidalysin (B) and protein lysates taken at 2 h for western blot analysis. Lysates were immunoblotted for total c-Fos, phospho-MKP1, phospho-ERK1/2, phospho-p38, phospho-SAPK/JNK or α-actin. Data are representative of 3 independent experiments.

Figure 6. Gab1, Grb2, Shc and Shp2 adaptors mediate *C. albicans- and* candidalysin-induced cytokine secretion in oral epithelial cells. Knockdown of Gab1, Grb2 or Shc or inhibition of Shp2 suppresses G-CSF, GM-CSF, IL-6, and IL-1β secretion. A-D) Following siRNA mediated knockdown or E-F) pre-treatment with the Shp2 inhibitor, SHP099HCL for 1 h, cells were either infected with the indicated strains or stimulated with candidalysin and supernatants collected after 24 h. Samples were analysed by magnetic Luminex assay to measure cytokine secretion. Data are the mean (±SD) of three biological replicates. Statistical significance was assessed by one way ANOVA with Bonferroni's multiple comparisons test; *P < 0.05, **P < 0.01, ***P<0.001, ****P<0.0001.

Figure 7. Gab1, Grb2, Shc and Shp2 adaptors mediate the candidalysin-induced MAPK events that trigger the epithelial cytokine response. *C. albicans* infections are initiated by increased fungal burden with associated hypha formation and the secretion of candidalysin (Clys). When accumulated at sufficient concentrations, candidalysin interacts with the cell membrane to form pore-like structures that results in membrane damage, alarmin release and calcium influx. These events lead to the activation of matrix metalloproteinases (MMPs) and the cleavage/release of epidermal growth factor receptor (EGFR) ligands, which ultimately activates EGFR. EGFR activation leads to the recruitment and the activation of the Gab1, Grb2, Shc, Shp2 and cCbl adaptor proteins which mediate MKP1 and cFos activation via the MAPK-ERK1/2 signalling pathway. This activation contributes to the induction of GMCSF and GCSF (and potential neutrophil recruitment), as well as IL-6, IL-1α and IL-1β which mediates the next stage of the innate immune response (Figure created with Biorender).
