72

73   **Abstract**

74   Malformations of cortical development (MCD) are neurological conditions displaying focal
75   disruption of cortical architecture and cellular organization arising during embryogenesis, largely
76   from somatic mosaic mutations. Identifying the genetic causes of MCD has been a challenge, as
77   mutations remain at low allelic fractions in brain tissue resected to treat epilepsy. Here, we report
78   a genetic atlas from 317 brain resections, identifying 69 mutated genes through intensive
79   profiling of somatic mutations, combining whole-exome and targeted-amplicon sequencing with
80   functional validation and single-cell sequencing. Genotype-phenotype correlation analysis
81   elucidated specific MCD gene sets associating distinct pathophysiological and clinical
82   phenotypes. The unique spatiotemporal expression patterns identified by comparing single-
83   nucleus transcriptional sequences of mutated genes in control and patient brains implicate critical
84   roles in excitatory neurogenic pools during brain development, and in promoting neuronal
85   hyperexcitability after birth.

86

87   **Introduction**

88   MCDs are heterogeneous groups of neurodevelopmental disorders with localized malformation
89   of cortical structures, often presenting with intractable epilepsy[1]. Major MCD subtypes include
90   different classes of focal cortical dysplasia (FCD), hemimegalencephaly (HME), and tuberous
91   sclerosis complex (TSC)[2]. The International League Against Epilepsy (ILAE) has classified FCD

92 subtypes based on neuropathological features and cell types[3]. MCD patients often undergo
93 surgical resection of the lesion to treat drug-refractory epilepsy, which has led to remarkable
94 clinical benefits in published series[4]. The abnormal histology of resected regions includes loss of
95 lamination of cortical layers, enlarged dysplastic neurons, or balloon cells, sometimes
96 accompanied by other brain abnormalities. But similar to brain tumors, it can be difficult to
97 predict pathology prior to surgery.
98   Again, like with brain tumors, genetic studies may offer insights into mechanisms.
99 Somatic mTOR pathway gene mutations are frequently detected in HME and type II FCD foci[5,6].
100 Recently, small- or medium-size cohort studies (<100 cases) have confirmed these results and
101 have correlated defects in neuronal migration, cell size, and neurophysiology[7]. Still, the vast
102 majority of MCD cases still remain genetically unsolved, suggesting other genes or modules
103 contribute to MCD.
104   Detecting mutant alleles in bulk resected foci from MCD patients is challenging because
105 unlike in brain tumors, the mutant cells in MCD are probably not hyperproliferative, and thus
106 variant allelic fraction (VAF) are often <5%, diluted by genomes of surrounding non-mutated
107 cells[8]. Fortunately, new computational algorithms have helped reduce false-positive and false-
108 negative signals, even when no 'normal' paired sample is available for comparison[9-11]. The NIH-
109 supported Brain Somatic Mosaicism Network established the 'BSMN common pipeline',
110 incorporating a 'best practice' workflow to reliably and reproducibly identify somatic variants
111 contributed by members of the Network[12]. With these advances, we thus assessed the possibility
112 of gene networks beyond mTOR that could underlie MCDs. This new gene discovery may give
113 insights into novel druggable pathways in cases of incomplete resection due to regional
114 importance or drug-resistant forms of MCD.
115

116 **Results**
117 **The genetic landscape of MCD from targeted and unbiased sequencing**
118 To perform a thorough genetic screening of somatic mutations in resected epileptic tissue, we
119 formed the FCD Neurogenetics Consortium and enrolled 327 samples that met clinical and
120 pathological criteria for FCD or HME. We excluded TSC from our enrollment criteria because
121 genes are already well known. Our cohort included 31 HME cases, 98 type I-, 142 type II-, 32
122 type III-, and 12 unclassified-FCD cases. We included acute resected brains from 10
123 neurotypicals and 2 TSC cases for comparison (Fig. 1a, supplementary table 1). Patients with
124 environmental causes, syndromic presentations, inherited mutations, multifocal lesions, or
125 tumors were excluded (Methods).
126   We used a three-phase genetic screening, each followed by filtering for likely causative
127 mutations using published methods[13,14], and each followed by orthogonal targeted amplicon
128 sequencing (TASeq) intra-case validation and VAF quantification compared with controls
129 (~5000 X, TASeq)(Fig. 1b). In Phase 1, we performed amplicon sequencing (AmpliSeq, ~1000
130 X) profiling the entire open reading frame of 87 genes previously detected in FCD/HMEs or
131 known PI3K-AKT3-mTOR interactors ('MCD panel v1', Supplementary Table 2a). In Phase 2,
132 for 75 unsolved cases from Phase 1 and additionally collected 54 cases, we performed unbiased
133 deep whole-exome sequencing (WES, ~300 X) on paired samples, where available, or on
134 unpaired samples (i.e. brain plus blood/saliva vs. brain only). In Phase 3, from an additional
135 subcohort of 132 new cases, we designed the 'MCD panel v2' (Supplementary Table 2b)
136 including known and novel genes detected in Phases 1 and 2 (Extended Data Fig. 1, Methods).

3

137   We re-sequenced unsolved cases from Phase 2, expecting that the higher read depth afforded by
138   panel sequencing could provide greater sensitivity to detect low VAF mutations, and used
139   BSMN best practice guidelines for mapping and variant calling[12].
140   From Phases 1 to 3, 1181 candidate somatic SNVs were identified. Of these, 628 were
141   excluded based on gnomAD allele frequencies, dinucleotide repeats, homopolymers, and
142   additional BSMN established criteria (Methods)[15,16]. This yielded 554 candidate somatic SNV
143   that were further assessed by TASeq, yielding 108 validated somatic SNV calls (19.4%
144   validation rate, Fig. 1c, Supplementary Table 3), compared to other BSMN effort validation rates
145   in WGS[12,17]. In detail, 15, 67, and 26 validated somatic SNV calls were derivated from phase1, 2,
146   and phase 3, respectively. The measured VAFs between the AmpliSeq/WES and TASeq were
147   correlated as expected (R^2= 0.7243) (Fig. 1d). Of the 69 candidate MCD genes mutated in 76
148   patients, 8 were recurrently mutated, including known mTOR pathway genes as well as several
149   novel candidates (Fig. 1e).
150   We estimate only ~7% of mutations identified are likely attributable to false discovery
151   during variant calling, based upon background mutation rate in 75 BSMN neurotypical brain
152   samples, and published experience from the BSMN[12,18], processed with the same workflow (see
153   Methods). Thus, 93% of our candidate MCD mutations would not have been identified in a size-
154   matched neurotypical control cohort.
155   Most patients (80.52%, 62 cases) showed a single somatic mutation, but some showed two
156   somatic mutations (14.29%, 11 cases), and some showed more than two mutations (5.19%, 4
157   cases). Interestingly, HME-4144 showed 11 different somatic mutations, all of which were
158   validated with TASeq. Although there are several possible explanations for HME-4144, we
159   expect this reflects clonal expansion from a driver mutation, with detection of multiple passenger
160   mutations, as reported in brain tumors[19].
161   Single-base mutational signatures (SBS) were developed to describe potential mutational
162   mechanisms in human disease[20]. We found 60.2% of mutations were C>T, likely arising from
163   DNA epigenetic marks[21] (Extended Data Fig. 2). Enrichment of SBS1 and SBS5, clock-like
164   mutational signatures suggest endogenous mutations arising during corticogenesis DNA
165   replication.

166

Functional dissection of the MCD genes

167
168   Interestingly, most validated genes were non-recurrently mutated (88.4%, 61 of 69) in our
169   cohort, suggesting substantial genetic heterogeneity in MCD. This nevertheless provided an
170   opportunity to study converging functional gene networks. Thus, we performed Markov
171   clustering with a STRING network generated from the putative MCD genes[22], as well as recently
172   reported novel MCD candidates (*NAV2, EEF2, CASK, NF1, KRAS, PTPN11*)[23,24] (Fig. 2a). We
173   identified four clusters, with cluster 1 ("mTOR pathway") showing the highest term enrichment
174   to the mTOR/MAP kinase signaling, supporting prior results for Type II MCDs. Cluster 1 also
175   highlighted newly identified genes *FGFR2, KLHL22, RRAGA, PPP2R5D, PIK3R3, EEF2*,
176   *EIF4G1,* and *MAPK9*. Cluster 2 identified "Calcium Dynamics" and included genes *ATP2A1,*
177   *RYR2, RYR3*, *PSEN2, TTN*, *UTRN*. Cluster 3 was labeled "Synaptic Functions" and included
178   genes *CASK, GRIN2C, and PPFIA4*. Cluster 4 was labeled "Gene Expression" and included
179   intellectual disability genes, mostly involved in nuclear function, including *NUP214, PRR14,*
180   *PCNT, NIPBL, SRCAP, ASH1L, TRIP12,* and *MED13* (Fig. 2b).

181   Notably, *ATP2A1, PPFIA4,* and *NIPBL* were recurrently mutated, either within our
182 cohort or with a recent report[24] (Extended Data Fig. 3a-b), occurring within the latter 3 clusters.
183 While these clusters were not previously reported in MCDs, they were previously implicated in
184 epilepsy, neurodevelopmental and neurodegenerative disease[25,26], suggesting functional overlap
185 with MCDs. We further performed ClueGO analysis and found enrichment in mTOR signaling,
186 focal adhesion assembly, cardiac muscle cell contraction, and artery morphogenesis (Extended
187 Data Fig. 4). ClueGO also displayed isolated gene ontology (GO) term clusters such as 'calcium
188 ion import' and 'protein localization to synapse'.

189

190 **Functional validation of selected module genes in embryonic mouse brain**
191 To investigate the roles of novel MCD genes and modules, we selected two potential mTOR
192 pathway mutations (*RRAGA* p.H226R, *KLHL22* p.R38Q)*,* and non-mTOR gene mutation
193 (*GRIN2C* p.T529M), discovered in FCD-7967, 3560, and 5157, respectively. *RRAGA* encodes
194 Ras-related GTP binding A (RAGA), a GTPase sensing amino acid and activating mTOR
195 signaling, with two functional domains: GTPase domain and C-terminal 'roadblock' domain
196 (CRD) [27]. The mosaic p.H226R mutation occurs within the CRD, which binds to the RAGB
197 protein and is conserved throughout vertebrate evolution (Extended Data Fig. 3c) and thus could
198 change binding affinity. *KLHL22* encodes a CUL3 adaptor, determining E3 ubiquitin ligase
199 specificity. The CUL3-KLHL22 complex mediates the degradation of DEPDC5, required for
200 mTORC1 activation[28]. The KLHL22 *p.*R38Q variant in FCD-3560 is near the BTB (Broad-
201 Complex, Tramtrack, and Bric- à-brac) domain that interacts with CUL3 (Extended Data Fig. 3d),
202 suggesting the variant could enhance mTORC1 activity. *GRIN2C* encodes a subunit of the
203 NMDA receptor regulating synaptic plasticity, memory, and cognition[29,30], dysfunction of which
204 is implicated in many neurocognitive diseases including epilepsy, neurodevelopment, and
205 tumors[31,32]. *GRIN2C* p.T529M mutation is located in the S1 glutamate ligand-binding domain
206 (S1 LBD) (Extended Data Fig. 3e). *GRIN2A* p.T531M mutation, an analog mutation of *GRIN2C*
207 p.T529M in our cohort, was previously reported in epilepsy-aphasia spectrum disorders, where it
208 increased NMDA receptors 'open-state' probability[32]. This suggests that the p.T529M mutation
209 activates the channel, likely in an mTOR independent fashion. Thus, all mutations assessed here
210 are likely gain-of-function and exert functional impact on cells in which they are expressed.
211   To test this hypothesis, we introduced mutant or wildtype (WT) genes co-expressing
212 enhanced green fluorescent protein (EGFP) into the dorsal subventricular zone via
213 electroporation at mouse embryonic day 14 (E14), then harvested tissue at either E18 to assess
214 migration, or at postnatal day 21 (P21) to assess cell size and phospho-S6 as a reporter of mTOR
215 activity[33] (Fig. 3a). In E18 cortices, we found EGFP-positive cells expressing mutant but not WT
216 forms of *RRAGA* and *KLHL22* showed significant migration defects of varying severity, whereas
217 mutant *GRIN2C* showed no defect (Fig. 3b). These migration defects in *RRAGA* and *KLHL22*
218 mutant cells replicate major findings of MCD disrupted cortical architecture.
219   We next assessed cellular phenotype at P21 with samples available in both mice and the
220 corresponding patients and found enlarged cell body area in both mutant forms of *KLHL22* and
221 *GRIN2C* compared to according wildtype. In contrast, the elevated levels of pS6 staining,
222 described previously in association with mTOR pathway mutations[6], was found only in mutant
223 *KLHL22,* but not in mutant *GRIN2C* mice (Fig. 3c).
224   To assess correlation with human samples, we assessed archived neuropathological tissue
225 sections for histology and pS6 activity. Similar to our mouse models, we found patient FCD-

226   3560 carrying *KLHL22* p.R38Q showed enlarged neurons that co-stained for excess pS6 staining,
227   whereas FCD-5157 carrying *GRIN2C* p.T529M showed only a slight increase in cell body size
228   and no evidence of excessive pS6 staining (Fig. 3d). While this analysis does not take into
229   account the genotype of individual cells, it suggests *KLHL22* but not *GRIN2C* mutations impact
230   mTOR signaling.

231

Genotype-phenotype correlations in MCD patients
233   To assess the phenotypic contributions of the MCD genes we found, we focused on 76 of our
234   'genetically solved' MCD cases, comparing detailed neuropathology, brain imaging, and clinical
235   course. We performed Pearson correlation followed by hierarchical clustering based upon ILAE
236   neuropathological diagnosis, compared with GO term-based curated genesets and whether the
237   genetic variant was present in COSMIC DB (Methods, Supplementary Table 3,4, Fig. 4). We
238   found that FCD Type IIA and Type IIB, and HME were more tightly clustered than FCD Type I
239   or III (Fig. 4a), likely reflecting shared neuropathological features that include large dysplastic
240   neurons. As expected, FCD Type IIA, Type IIB, and HME were positively associated with the
241   mTOR pathway GO term and COSMIC DB entry, FCD Type III, however, was associated with
242   the MAPK pathway, consistent with recent publications implicating *BRAF, FGFR2, NOD2,* and
243   *MAPK9* in their etiology[34-36]. FCD Type I showed few strong positive correlations for
244   glycosylation, consistent with recent findings of somatic mutations in *SLC35A2* and *CANT1*[37,38].
245   We next investigated correlations between clinical phenotypes extracted from detailed
246   medical records including seizure type, neuropsychological examination, and positron emission
247   tomography (PET) metabolism, often used to help localize seizure focus[39,40]. Seizure frequency,
248   early age of onset, Engel score, and history of infantile spasms drove clinical clustering, likely
249   reflecting shared clinical features in the most challenging patients. Focusing on the correlations,
250   PET hypometabolism correlated positively with COSMIC DB entry, and negatively with MAPK
251   and Ubiquitination (Fig. 4b), suggesting divergent metabolic mechanisms. Abnormal
252   neurological examination correlated positively with COSMIC DB entry and negatively with
253   Type I histology, which may reflect the effects of mutations on baseline neurological function.

254

MCD genes enriched in the excitatory neuronal lineage
256   To infer the cell type in which MCD genes function, we accessed a published single-cell
257   transcriptome dataset from the 2nd-trimester human telencephalon, at a time when these
258   mutations probably arose[41] (Fig. 5a). We generated an eigengene, by mapping the average
259   expression of our MCD genes against the UMAP plot (Fig. 5b). This showed a strong positive
260   correlation with dividing radial glial cells, and a moderate correlation in dividing intermediate
261   progenitor cells (IPCs) and mature excitatory neuron cells. We found a negative correlation with
262   inhibitory neuronal lineages including medial and central ganglionic eminences (MGE, CGE)
263   and mature interneuron clusters (Fig. 5c). We next performed deconvolution into four major
264   module eigengene (MEs), which revealed cell types classified as mature excitatory neurons
265   (turquoise and blue), microglia (brown), and unassigned (grey) (Fig. 5d). Quantification
266   supported enrichment in dividing radial glia, excitatory neurons, and microglia, the latter likely
267   driven by MCD candidate genes *IRF8* and *VSIG4* (Fig. 5e). Taken together, the expression of
268   MCD genes is more enriched in dorsal cortex neurogenic pools and implicated in the maturation
269   of excitatory rather than inhibitory neurogenic pools, as well as microglia.

270

MCD gene expression is enriched in dysplastic cells

We next performed differentially expressed gene (DEG) analysis in the MCD brain. We reasoned that single-nucleus transcriptomes would be more revealing than bulk transcriptomes, but the average VAF of ~6% in our MCD cohort meant that the vast majority of sequenced cells would be genetically wild-type. We thus decided to focus snRNAseq on resected cortex from patients with shared pathological MCD hallmarks but higher VAFs. We selected four resected brain samples, two from patients with HME (HME-4688 *PIK3CA* p.E545K, 25.1% VAF and HME-6593 *PIK3CA* p.H1047R, 13.1% VAF), and two from patients with TSC meet full diagnostic criteria. We also included brains from four neurotypical cases as a comparison and sequenced a total of 22,067 nuclei (see Methods).

While the TSC brain single nucleus transcriptomes showed substantial overlapping pools with controls, HME brains showed a distinct UMAP distribution, located at the edges of the plot (Fig. 6a). We found that very few HME cells matched expression patterns for typical brain cells, even after standard normalization and scaling (Fig. 6b, Extended Data Fig. 5a, see Methods). We thus labeled these clusters according to their closest relatives based upon established marker gene expression in the control brain, labeled as 'astrocyte-like (Ast-L)' or 'oligodendrocyte-like (OD-L)'. Even with these categories, some clusters remained undefined (U) (Extended Data Fig. 5b,c). Interestingly, there was no single cell cluster that matched the VAF in the brain, suggesting the mutant cells, as well as surrounding non-mutant cells, have dramatically disrupted transcriptomes.

We noted that several of the HME clusters showed excessive expression of fibroblast growth factor receptor (FGFR) gene families, specifically *FGFR1* in cluster U1/2 in HME, *FGFR2/3* in cluster Ast-L1/3 and OD-L, *EGFR* in Ast-L1/3 and U1/2, and *PDGFRA* in cluster U1/2 (Extended Data Fig. 5b,c). To identify the cell types expressing these genes, we performed RNA in situ hybridization in HME brain sections followed by hematoxylin-eosin staining. We found co-localization of these same *FGFR* family, *EGFR,* and *PDGFRA* transcripts with dysplastic cells (Extended Data Fig. 6). Previous experiments indicate that it is most often the dysplastic cells within HME and MCD that carry disease mutations[7], suggesting an effect of these mutations on growth factor receptor expressions that correlates with dysplasia.

Next, we investigated the expression patterns of MCD genes in this HME/TSC snRNAseq dataset. An eigengene representing expression patterns of MCD genes was enriched in Ast-L1/3 and OD-L, which were labeled as dysplastic cells (Fig. 6c). Interestingly, the individual MCD genes displayed converging expression patterns resulting in six different eigengenes (Fig. 6d, gene members for each eigengene are described in Extended Data Fig. 7) which show distinct enrichment patterns across cell types (Fig. 6e), implying that membership of each eigengene may be associated with the pathophysiology of the corresponding dysplastic cell type in HMEs. We performed a pseudo-bulk DEG analysis comparing HME with CTRL and detected 590 up-regulated genes and 1096 down-regulated genes. Intriguingly, 20% (15/75) of MCD mutated genes in our list overlapped with DEGs of HME. Permutation testing suggests that this overlap is unlikely to have arisen by chance (Fig. 6f, see Methods). Taken together, many MCD genes are misregulated in MCD-specific cell types, suggesting that our MCD genes may play important roles in the pathogenesis of dysplastic cells in MCDs.

Discussion

7

315   In this study, we use a multiomics approach to study the genetic landscape of MCD in the largest
316   reported cohort to date. We confirmed the important role of mTOR/MAP kinase and
317   glycosylation pathways, seen in about 60.5% of those with mutations. Moreover, our results also
318   linked novel biological processes including gene expression, synaptic function, and calcium
319   dynamics, which made up the other 39.5% of mutations. Nevertheless, only 76 of 317 patients
320   showed one or more putative somatic mutations as a likely cause of MCD. There could be
321   numerous causes for the relatively low solve rate in MCD, including the potential to miss very
322   low VAF mutations and the contribution of complex mutations like structural variants or short
323   tandem repeats polymorphism. Finally, although patients with environmental causes, syndromic,
324   or inherited causes were excluded from our cohort, these factors could still contribute to MCD.
325   With our approach, we identified several recurrently-mutated genes not previously
326   implicated in MCD. Confirming the remaining candidate and identifying further MCD candidate
327   genes will require larger MCD cohorts. Including novel MCD candidate genes emerging from
328   300X WES into the 1000X Phase 3 AmpliSeq allowed both confirmation of mutations, a more
329   accurate estimate of VAF, and identification of additional patients with these genes mutated that
330   would have been perhaps missed with 300X WES. Functional validation by modeling mutations
331   in embryonic mouse brains suggests that most candidate genes we identified are likely to
332   contribute to disease. Perhaps it is not surprising that there are so many MCD genes, because
333   such mutations may avoid embryonic lethality due to their expression in just a small subset of
334   cells. Like with de novo germline mutations discovered in autism, we suggest that there could be
335   dozens if not hundreds of additional MCD genes, based in part upon the low number of
336   recurrently mutated genes [42].
337   The four gene networks, mTOR/MAP kinase, calcium dynamics, synapse, and gene
338   expression, are intriguing, as they should play important roles for these genes both during brain
339   development and homeostasis. All four pathways are critical both for corticogenesis during
340   neurogenesis and neuronal migration, as well as neuronal excitability. For instance, calcium
341   dynamics is shown to regulate cytoskeletal activity and excitability[43,44]. The genotypic
342   information also showed correlations with clinical features, for instance, PET brain
343   hypometabolism and abnormality in the neurological examination correlated with COSMIC DB
344   variants, opening the possibility to predict genotype based on phenotype.
345   We also characterized the expression patterns of MCD genes in the developmentally
346   normal and MCD brains at single-cell resolution. The cell types most strongly expressing
347   candidate MCD genes include dorsal forebrain radial glial progenitors and their daughter
348   excitatory neurons, as well as brain microglia, fitting well with the likely site of origin of somatic
349   brain mutations[45]. Surprisingly, the dramatic gene dysregulation seen in the HME brain skewed
350   the UMAP plots in ways that could not be accounted for simply by the VAF. The fact that the
351   MCD genes also showed the strongest enrichment with these same clusters suggests that the
352   MCD genes are very likely to have pivotal roles in the HME condition. Prior studies on MCD
353   indicated that dysplastic cells express markers for both glia and neurons[46]. Our findings,
354   however, suggest that MCD mutations drive critical roles predominantly in dividing radial glia,
355   with profound effects on lineage and cellular dysplasia. To conclude, the MCD genes in patient
356   brains found in our study demonstrated critical roles during cortical development, significantly
357   correlate with patient phenotypes, and could open doors to novel treatments for MCDs.
358

Online Methods

Overview of the FCD cohort
This study is a multi-center international collaboration. We recruited a cohort of 317 individuals
from the 'FCD Neurogenetics Consortium' (see the member list). These individuals were
diagnosed with FCD type I, II, III, HME, or TSC and underwent surgical resection to treat drug-
resistant epilepsy between 2013 and 2021. Any cases that underwent surgical resection due to
environmental factors, for example, stroke, or acute trauma, were excluded. For each individual,
resected brain tissue was collected, along with paired blood or saliva samples and parental
samples, where available. Clinical history, pre- and post-operative brain imaging,
histopathology, ILAE classification according to the surgical tissue pathology report, and Engel
surgical outcome score (at least two years after surgery) were collected, when available.

Informed consent and study approval
The study protocol was approved by the UC San Diego IRB (#140028). Informed consent was
obtained from all participants or their legal guardians at the time of enrollment.

DNA extraction
Pulverized cortical samples (~0.3 g) were homogenized with a Pellet Pestle Motor (Kimble,
#749540-0000) or Handheld Homogenizer Motor (Fisherbrand, #150) depending on the size of
the tissue, and resuspended with 450 μL RLT buffer (Qiagen, #40724) in a 1.5 ml
microcentrifuge tube (USA Scientific, #1615-5500). Homogenates were then vortexed for 1
minute and incubated at 70°C for 30 minutes. 50 μl Bond-Breaker TCEP solution (Thermo
Scientific, #77720) and 120 mg stainless steel beads with 0.2 mm diameter (Next Advance,
#SSB02) were added, and cellular disruption was performed for 5 minutes on a DisruptorGenie
(Scientific industries). The supernatant was transferred to a DNA Mini Column from an AllPrep
DNA/RNA Mini Kit (Qiagen, #80204) and centrifuged at 8500 xg for 30 seconds. The column
was then washed with Buffer AW1 (kit-supplied), centrifuged at 8500 xg for 30 seconds and
washed again with Buffer AW2 (kit-supplied), and then centrifuged at full speed for 2 minutes.
The DNA was eluted two times with 50 μl of pre-heated (70°C) EB (kit-supplied) through
centrifugation at 8,500 xg for 1 minute.

MPAS and WES sequencing for somatic mutation candidates
Massive parallel amplicon sequencing (MPAS) and whole-exome sequencing (WES) were used
at different phases to perform the genetic screening within available samples from the cohort.
Customized AmpliSeq DNA panels for Illumina (Illumina, #20020495) were used for Massive
Parallel Amplicon Sequencing[17]. 87 or 82 genes related to the mTOR pathway or curated based
on the results of Phase 1 and 2, respectively, were subjected to the AmpliSeq design system; a
list of designed genes is provided in Supplementary Table 2a-b. Two pools were designed for
tiling the capture region. Genomic DNA from extracted tissue was diluted to 5 ng/uL in low TE
provided in AmpliSeq Library PLUS (384 Reactions) kit (Illumina, #20019103). AmpliSeq was
carried out following the manufacturer's protocol (document #1000000036408v07). For
amplification, 14 cycles each with 8 minutes were used. After amplification and FUPA
treatment, libraries were barcoded with AmpliSeq CD Indexes (Illumina, #20031676) and pooled

9

403 with similar molecular numbers based on measurements made with a Qubit dsDNA High
404 Sensitivity kit (Thermo Fisher Scientific, #Q32854) and a plate reader (Eppendorf, PlateReader
405 AF2200). The pooled libraries were subjected to Illumina NovaSeq 6000 platform for PE150
406 sequencing. The AmpliSeq design in the 'Phase 1' is under the design ID IAA7610, and the
407 AmpliSeq design in 'Phase 3' is under the design ID IAA26010.
408   Genomic DNA (~ 1.0 µg) was prepared for whole-exome sequencing, and libraries were
409 captured using the Agilent SureSelect XT Human All Exon v.5 or Nextera DNA Exome kits.
410 Then, 100, 125, or 150 bp paired-end reads (median insert size ~ 210 bp) were generated using
411 the Illumina HiSeq X 2500 platform. The sequencing experiments were designed to yield three
412 datasets of ~ 100X coverage on each sample, with a coverage goal of 300X from the brain and
413 100X from blood/saliva.

414

415 **Somatic variant calling from MPAS and WES**
416 Reads were aligned to GRCh37 using BWA (version 3.7.16a), sorted per each read group, and
417 merged into a single BAM file with Sambamba (version 0.6.7). The merged BAM files were
418 marked for duplicate reads using PICARD (v2.12.1), duplicated reads were not removed for
419 MPAS because of the nature of the method. Then, we performed indel realignment and base
420 quality recalibration using GATK (v3.7–0), resulting in the final uniformed processed BAM
421 files.
422   Both tissue-specific and tissue-shared mosaic variants were called from the MPAS and
423 WES sequencing data. MPAS and WES variants were called according to the availability of the
424 control tissue. Brain- and blood/saliva-specific variants were called using MuTect2 (GATK3.8)
425 paired mode and Strelka2 somatic mode[47]; the BAM files from the brain sample (combined and
426 non-combined from independent sequencing libraries) and blood/saliva samples were treated as
427 "tumor-normal" and "normal-tumor" pairs separately and cross-compared between each other.
428 Variants called by both callers were listed. Mosaic variants shared between the brain and
429 fibroblast samples were called using the single mode of MosaicHunter[11] by either combining all
430 brain replicates or calling each separate sample. Variants that passed all the MosaicHunter filters
431 also were listed. Somatic variants from WES data were further called by GATK (v3.7–0)
432 haplotypecaller with ploidy parameter set to 50, followed by a series of heuristic filters described
433 as the best-practice by the Brain somatic mosaicism network[12], tissue-shared variants were called
434 by the combination of MuTect2[48] (GATK 3.8) single-mode and DeepMosaic[10].
435   A union of different pipelines was selected to get maximum sensitivity. Mosaic
436 candidates from the combined lists were further filtered using the following criteria: (i) the
437 variant had more than 3 reads for the alternative allele; (ii) the variant was not present in UCSC
438 repeat masker or segmental duplications; (iii) the variant was at least 2 bp away from a
439 homopolymeric tract; and (iv) the variant exhibited a gnomAD allele frequency lower than
440 0.001. Variants that exist in the 1000 genome project (phase 3) also were excluded from the
441 analysis. Variants from both exome data sources were tested and a combination of tissue-specific
442 mosaic variants and tissue-shared mosaic variants were collected and the credible interval of
443 VAFs was calculated using a Bayesian-based method described previously[49]. To filter for
444 candidate disease-causing variants for FCD, we further filtered out synonymous variants in
445 coding regions, variants with CADD Phred score < 25, and candidates that fell out of coding
446 regions and were not predicted to affect splicing by ANNOVAR.

False discovery estimation

To calculate the false discovery of random variants detected in normal samples, we incorporated 75 normal control samples (71 brains and 4 other organs) previously sequenced with 250-300X WGS, which should provide similar sensitivity as our exomes, the deep WGS were generated by efforts from the NIMH Brain Somatic Mosaicism Consortium[12], from controls[17], and from our recent mutation detection pipeline[18]. Variants were filtered based on the identical criteria as described in the above data analysis part, with >0.01 VAF, all on exonic regions defined by NCBI, and CADD score >25. While 13 variants remain positive from this pipeline from the 75 samples (0.17 per control), 306 candidate variants were determined in our 134 MCD exomes (2.28 per MCD case), which lead to an estimated 7.59% per sample false discovery rate (Supplementary Table 5).

Orthogonal validation and quantification of mosaic mutations with targeted amplicon sequencing

Targeted amplicon sequencing (TASeq) with Illumina TruSeq was performed with a coverage goal of >1000X for 554 candidate variants detected by computational pipelines described above for both MPAS and WES, to experimentally validate the mosaic candidates before functional assessment. PCR products for sequencing were designed with a target length of 160-190 bp with primers being at least 60 bp away from the base of interest. Primers were designed using the command-line tool of Primer3[50,51] with a Python (v3.7.3) wrapper[13,14]. PCR was performed according to standard procedures using GoTaq Colorless Master Mix (Promega, M7832) on sperm, blood, and an unrelated control. Amplicons were enzymatically cleaned with ExoI (NEB, M0293S) and SAP (NEB, M0371S) treatment. Following normalization with the Qubit HS Kit (ThermFisher Scientific, Q33231), amplification products were processed according to the manufacturer's protocol with AMPure XP beads (Beckman Coulter, A63882) at a ratio of 1.2x. Library preparation was performed according to the manufacturer's protocol using a Kapa Hyper Prep Kit (Kapa Biosystems, KK8501) and barcoded independently with unique dual indexes (IDT for Illumina, 20022370). The libraries were sequenced on Illumina HiSeq 4000 or NovaSeq 6000 platform with 100 bp paired-end reads.

Mutational signature analysis

Mutational signature analysis was performed using a web-based somatic mutation analysis toolkit (Mutalisk)[52]. PCAWG SigProfiler full screening model was used.

STRING analysis

STRING analysis was performed by STRING v11[22]. A total of 75 MCD genes were loaded as input and MCL clustering was performed. The terms in Gene Ontology (GO), KEGG pathways, and Top 10 terms GO or KEGG pathways were shown in Fig. 2b. If there are less than 10 terms for those terms (such as clusters 3 and 4 in Fig. 2), we included all the terms in GO or KEGG pathways, Local network cluster (STRING), Reactome pathways, and Disease-gene associations (DISEASES) to show the enriched terms. Visualization was performed by Cytoscape v3.9.

ClueGO analysis

11

489　Visualization of the functionally grouped biological terms was performed by ClueGO v2.5 [53], a
490　Cytoscape plug-in. A total of 75 MCD genes from Fig. 2 were loaded and GO terms in the
491　'Biological Process' category were used for visualization. Terms with a p < 0.01, a minimum
492　count of 3, and an enrichment factor > 1.5, are grouped into clusters based on membership
493　similarities.

494

495　**Animals**
496　Pregnant Crl: CD1(ICR) mice for mouse modeling were purchased from Charles River
497　Laboratory. All mice used were maintained under standard group housing laboratory conditions
498　with 12 hours light/dark cycle and free access to food and water. The age and number of mice
499　used for each experiment are detailed in the figure legends. The sex of the embryos used was not
500　tested. All work with mice was performed in accordance with UCSD IACUC protocol S15113.

501

502　**DNA constructs**
503　*RRAGA*, *KLHL22*, and *RHOA* ORF regions were amplified from the hORFeome library and
504　inserted into the pCIG2 (pCAG-IRES-GFP) vector. *GRIN2C* ORF region was purchased from
505　DNASU Plasmid Repository in Arizona State University Biodesign Institute. All sequences of
506　clones were confirmed by sanger sequencing.

507

508　**In utero electroporation**
509　In utero electroporation was performed as described previously[54] with modifications as follows.
510　Endotoxin-free plasmids (0.5–1 µg) plus 0.1% Fast Green (Sigma, catalog no. 7252) was injected
511　into one lateral ventricle of E14.5 embryos. Electroporation was performed by placing the anode
512　on the side of the DNA injection and the cathode on the other side of the head to target cortical
513　progenitors. Four pulses of 45 V for 50 ms with 455-ms intervals were used.

514

515　**Mouse brain section preparation**
516　An E18 mouse brain is fixed in 4% paraformaldehyde (PFA) for 2 hrs. For the P21 mouse brain,
517　a mouse was anesthetized by isoflurane and perfused by cold 1X PBS for 8 min and following
518　4% cold PFA for 8 min. The brains were dehydrated in 30% sucrose in 1x PBS for 48 hrs and
519　embedded in Tissue-Tek optimal cutting temperature compound and frozen on dry ice. A frozen
520　block was sectioned with 20 um thickness in a cryostat (CryoStar NX70, Thermo Fisher
521　Scientific) and placed on sliding glass. The attached sections were dried on a 50 ℃ heating block
522　for 3 hrs.

523

524　**Immunofluorescence staining and imaging**
525　A section was rehydrated and washed by 1X PBS for 10 min 3 times, permeabilized in PBST
526　(0.3% Triton X-100 in 1X PBS) for 10 min, and blocked by blocking solution (5% normal BSA
527　in 1X PBS) for 2 hrs in room temperature. Sections were stained with diluted primary antibodies
528　in the blocking solution overnight at 4 ℃. The next day, the sections were washed with PBST for
529　5 min three times and stained with secondary antibodies in blocking solution for 2 hrs in RT.
530　Blocking solution was dropped off from the slides and nuclei staining with DAPI solution
531　(0.1ug/ml of DAPI in PBST) was performed for 15 min. The slides were mounted with DAKO

532 fluorescent mount solution (catalog no. S3023). Zeiss 880 Airyscan Confocal is used for imaging
533 according to the manufacturer's instructions.

534

Antibodies

536 phospho-S6 (1:800 dilution, catalog no. 5364S ;Cell Signaling, AB_10694233), NeuN (1:100,
537 MAB377X; Sigma-Aldrich, AB_2149209), GFP (1:500, catalog no. GFP-1020, Aves Labs,
538 AB_10000240), Alexa Fluor Goat 488 chicken IgY (H+L) (1:1,000 dilution, catalog no. A-
539 11039, AB_2534096), Alexa Fluor 594 donkey anti-rabbit lgG (H+L) (1:1,000, catalog no.
540 R37119, AB_2556547).

541

Genotype-phenotype association

543 The functional modules to be tested were selected based on the enriched GO terms (Fig. 2 and
544 Extended Data Fig. 4). A given candidate MCD gene was assigned as a member to one or
545 multiple modules based on GO terms related to the given gene (results summarized in
546 Supplementary Table 3c). Subsequently, a given patient became a member of one (or multiple)
547 functional module(s) if the genes detected in that patient were assigned to that (those) functional
548 module(s). All available clinical information on the patient was collected and harmonized using
549 ILAE terms (summarized in Supplementary Table 4). Pearson correlation coefficients were
550 calculated by cor.test() function in R. The value of correlation coefficients were displayed as
551 colors in the heatmap of Fig. 4. If two groups with binary values were used for calculation, Phi
552 coefficient was used.

553

Single-nucleus RNA sequencing

555 A fresh-frozen brain tissue (~50 mg) was placed into a glass dounce homogenizer containing 1
556 ml cold lysis buffer (0.05 % (v/v) NP-40, 10 mM Tris (pH 7.4), 3 mM MgCl$_2$, 10 mM NaCl) and
557 dounce 10 times with a loose pestle and following 10 times with a tight pestle. The homogenate
558 was incubated for 10 min in RT. 9 ml of wash buffer (1% BSA in 1X PBS) was added to the
559 homogenate and filtered by a 30 um cell strainer. The strained homogenate was spun down in
560 500 g to remove the supernatant. The pellet was resuspended by 5 ml of wash buffer. Straining,
561 spinning down steps was performed once more, and the pellet was resuspended into 500 ul of
562 wash buffer. 10 ul of nuclei resuspension was mixed with counting solution (0.02 % Tween 20,
563 0.1ug/ml DAPI, 1% BSA in 1X PBS) and nuclei density was measured by manual nuclei
564 counting using DAPI signal. The resuspension was diluted by wash buffer to make the desired
565 concentration (800~1000 nuclei/ul). 1~4 samples were pooled together targeting 10000 nuclei
566 per reaction. Gel beads emulsion (GEM) generation, cDNA, and sequencing library
567 constructions were performed in accordance with instructions in the Chromium Single Cell 3'
568 Reagent Kits User Guide (v3.1). A library pool was sequenced with 800 million read pairs using
569 NovaSeq 6000.

570

Single-nucleus RNAseq bioinformatics pipeline

572 Fastq files from single-nucleus libraries were processed through Cell Ranger (v6.0.2) analysis
573 pipeline with –include-introns option and hg19 reference genome. Pooled library was
574 demultiplexed and singlets were taken by demuxlet. Seurat (v4) package was used to handle

575 single nuclei data objects. Protein coding genes were used for further downstream analysis.
576 Nuclei passed a control filter (number of genes > 500, number of reads >1000, percentage of
577 mitochondrial gene < 10%) was used for downstream analysis. Data were normalized and scaled
578 with the most variable 5000 features using the 'NormalizeData' and 'ScaleData' functions.
579 Dimensionality reduction by PCA and UMAP embedding was performed using runPCA and
580 runUMAP function. Clustering was performed by FindNeighbors and FindClusters function. Cell
581 type identification was performed using known cell type markers expressed in the brain
582 including excitatory/inhibitory neuron, astrocyte, oligodendrocyte, microglia, and endothelial
583 cell markers as well as using positive markers found by FindAllMarkers function with 3000 most
584 variable features in scaled data.

585

586 **Weighted gene co-expression network analysis**
587 'r-wgcna' package (v1.69) was used for WGCNA according to instructions (PMID: 19114008).
588 Briefly, a similarity matrix was generated based on Pearson's correlation coefficient value
589 among the top 3000 variable features in single-nucleus transcriptome data, which was used to
590 calculate the subsequently signed type of network adjacency matrix. Next, the topological
591 overlap matrix (TOM) and the corresponding dissimilarity (1-TOM) value were generated from
592 the adjacency matrix. Finally gene modules were generated by 'cutreeDynamic' function with
593 'tree' method, minAbsSplitHeight = 0.9 and minClusterSize = 30 option. Similar gene modules
594 were merged by 'mergeCloseModules' function with cutHeight = 0.25. String analysis was
595 performed using each gene module for the identification of the given module's functional
596 characteristics.

597

598 **RNAscope**
599 We used published methods and purchased target probes for genes of interest containing an 18-
600 25 base region complementary to the target, as spacer sequencing, and a 14 base Z-tail
601 sequence[55], including RNA pol III positive control and random sequence negative control,
602 following the manufacturer recommendations (Advanced Cell Diagnostics, Hayward, CA).
603 Images were acquired on a Leica STED Sp8 with Falcon microscope.

604

605 **Permutation analysis for the enrichment of MCD genes**
606 To test the enrichment of differentially expressed MCD genes in RNA sequencing against a
607 random distribution, we designed a permutation analysis. All human genes used in the single-cell
608 RNA-seq analysis (n=19909) were randomly shuffled 10,000 times and the same number of
609 genes as described in the differential expression analysis (n=1686) was selected for each shuffle.
610 The number of overlaps between each shuffle and the MCD candidates was compared and the
611 number of overlaps was used as the outcome and a null distribution was generated from the
612 10,000 shuffles. All 75 positively validated MCD genes are confirmed to be existing in the initial
613 gene list. After 10,000 permutations, the permutation p-value was calculated with numbers >=
614 observed overlap (p=0.0017 for the data shown in the main text).

615

616 **Statistical analyses**

617 Statistical analyses were performed by R or Prism 8 (GraphPad Software). Two-way ANOVA
618 and Sidak multiple comparisons were performed in Fig 3b with p-values of interaction between
619 genotype and bin factor. $****p < 0.0001$, $***p < 0.001$, $**p < 0.01$, $*p < 0.05$.

620

Code and data availability

622 Code to generate the figures and analyze the data are publically available on GitHub
623 (https://github.com/shishenyxx/MCD_mosaic). WES and AmpliSeq data are deployed on NIMH
624 Data Archive under study number 1484 "Comprehensive multiomic profiling of somatic
625 mutations in malformations of cortical development" and SRA under accession number
626 PRJNA821916: "Comprehensive multiomic profiling of somatic mutations in malformations of
627 cortical development". The snRNAseq R object was deposited in Single Cell Portal
628 (https://singlecell.broadinstitute.org/single_cell/study/SCP1815/comprehensive-multiomic-
629 profiling-of-somatic-mutations-in-malformations-of-cortical-development#study-download).

Competing Interests Statement

654 The authors declare no competing interests.

655

656

Figure 1. Comprehensive genetic profiling and validation of somatic variants in 327 MCD patients. (a) Representative MRI image of FCD-3588 (FCD type I), FCD-4514 (FCD type II), HME-1573, and a pie chart for the composition of our MCD cohort. Yellow arrow and dash: affected brain regions. (b) Workflow for comprehensive genetic profiling of MCD, using a three-phase approach from patient DNA. Each phase was followed by quantification/validation of each variant with target amplicon sequencing (TASeq). Phase 1] 1000 ×pilot screening of DNA with an 87-gene mTOR-related panel. Phase 2] 300 ×whole-exome sequencing (WES) with best-practice somatic variant discovery for novel candidate discovery. Phase 3] Cohort-level validation with an updated, high-confidence TASeq gene set based on knowledge from Phase 1 and 2. A subset of the somatic mutations was further functionally validated by mouse modeling. Candidate genes were annotated and correlated with external datasets such as STRING DB, clinical phenotype dataset, and newly generated single-nucleus RNAseq dataset from MCD brain. (c) Somatic variant calls were detected from all three phases of genetic discovery, yielding 108 validated somatic calls. (d) Correlation between square-root transformed (sqrt) AmpliSeq/WES variant allele fraction (VAF) and TASeq VAF. Solid line: best-fit line linear regression. Dotted lines: 95 % confidence band of the best-fit line. (e) Oncoplot with all 69 validated somatic SNVs from this study. Top: most patients had one gene mutated, a few patients had more than one gene mutated, and patient HME-4144 had 11 different validated gene mutations. Color: type of variant. * and #: recurrent genes in our cohort, and non-recurrent in our cohort but recurrent in other studies, respectively.

16
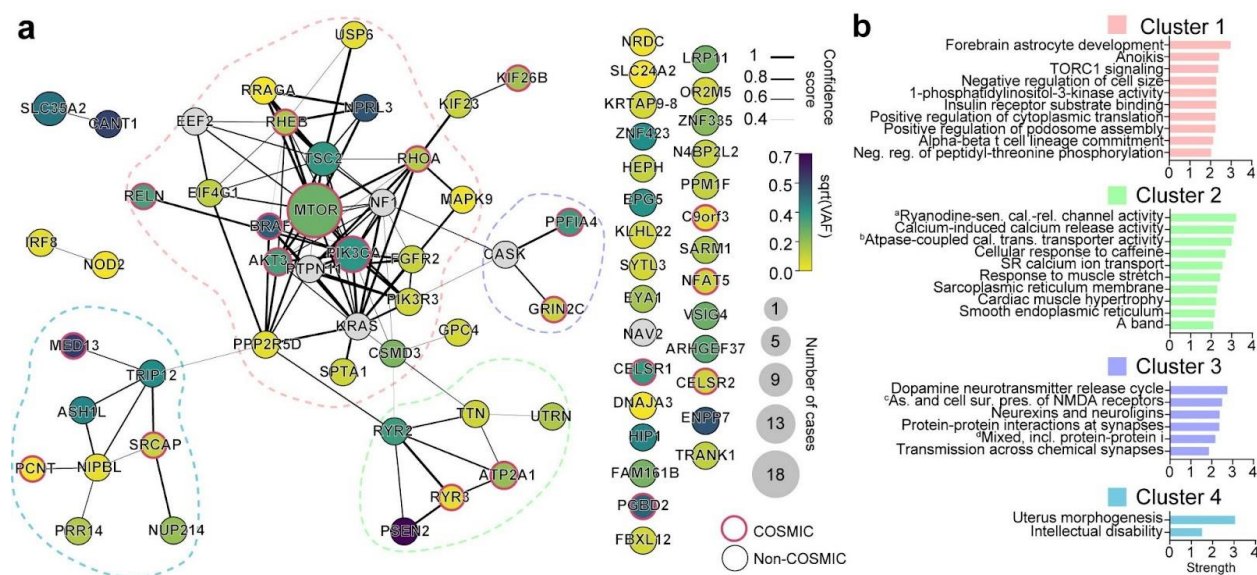

678
Figure 2. Four major gene networks were discovered from the comprehensive MCD gene profiling. (a) STRING DB pathway analysis of the 69 MCD discovered genes and six novel genes from recent publications identifies MTOR/MAP kinase pathway (pink, Cluster 1), Calcium dynamics (green, Cluster 2), Synapse (purple, Cluster 3), Gene expression (blue, Cluster 4). Edge thickness: confidence score calculated by STRING. Size and color of a node: square root transformed (sqrt) number of patients carrying a given mutation and average sqrt VAF across all patients, respectively. Non-clustered orphan genes are listed on the right. Red border: variant reported in the COSMIC database. (b) Gene Ontology (GO) analysis results confirmed the functions of compositions in each network. Top GO terms or KEGG pathways. Strength calculated by STRING.
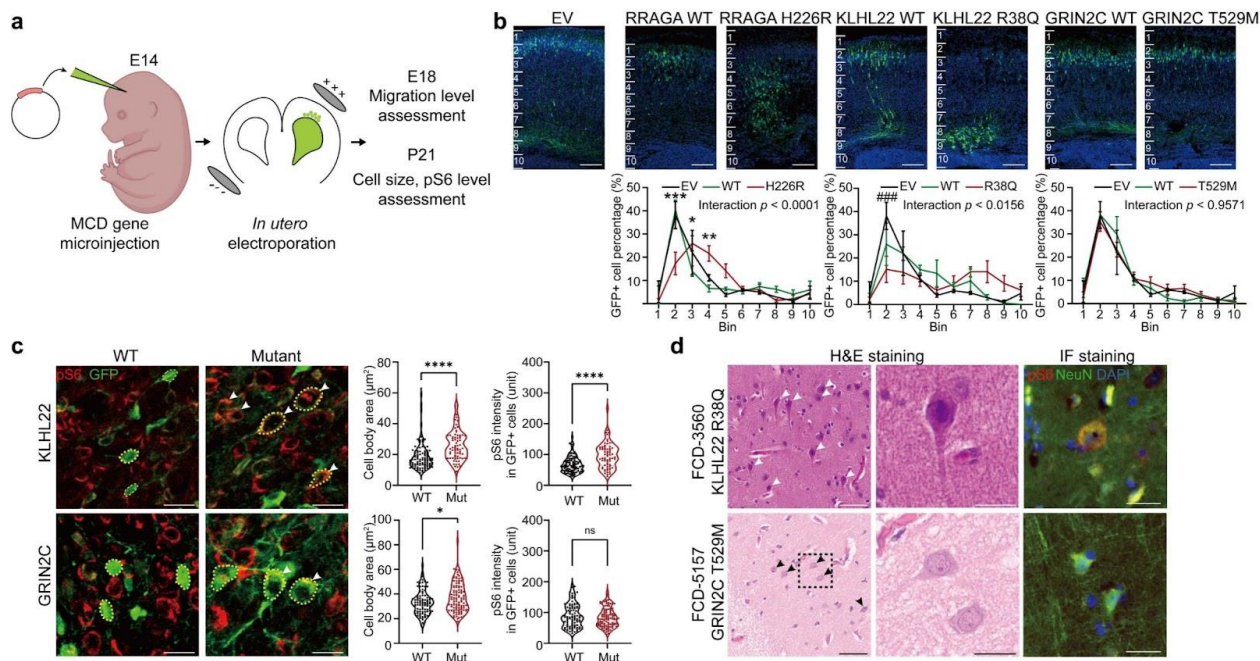

**Figure 3. Selected novel MCD somatic variants show functional defects in embryonic mouse brain and patient samples.** (a) Workflow for functional validation of candidate mosaic variants in mice. (b) Two different mutations in novel FCD type II genes, *RRAGA* H226R and *KLHL22* R38Q, but not a novel FCD type I gene, *GRIN2C*, disrupt cellular radial migration from the subventricular zone (SVZ). Below: two-way ANOVA and Sidak multiple comparisons with *p*-values of interaction between genotype and bin factor. * or # indicates a *p*-value in comparison between WT and mutant group, or EV and mutant group respectively. Ten bins from the surface of the cortex (top) to SVZ (bottom). Scale bar: 100 μm. Error bar: ±SE. (c) Immunofluorescence in postnatal day 21 mouse cortices for KLHL22 and GRIN2C wild-type (WT) or mutant isoform. Neurons expressing mutant KLHL22 and GRIN2C recapitulate histological phenotypes shown in (d), with enlarged cell bodies (white arrow) compared to WT isoforms (WT control), whereas only neurons expressing KLHL22 but not GRIN2C mutant isoform display increased pS6 levels compared to control. Dotted lines: examples of cell body size quantification. Two-sided Student's *t*-test. Scale bar: 20 μm. (d) H&E and phospho-S6 (pS6) staining of the resected brain from FCD-3560 and FCD-5157. Box area is zoomed in the middle image. Arrows: dysplastic cells. Right: Immunofluorescence (IF) for pS6 and NeuN. Note dysplastic pS6-positive neurons with increased pS6 levels are present in FCD-3560 but not in FCD-5157. Scale bar: 60 μm on the left, 20 μm on the middle and right. ****p < 0.0001; *p < 0.05; ns, non-significant. ###p < 0.001. EV: empty vector.
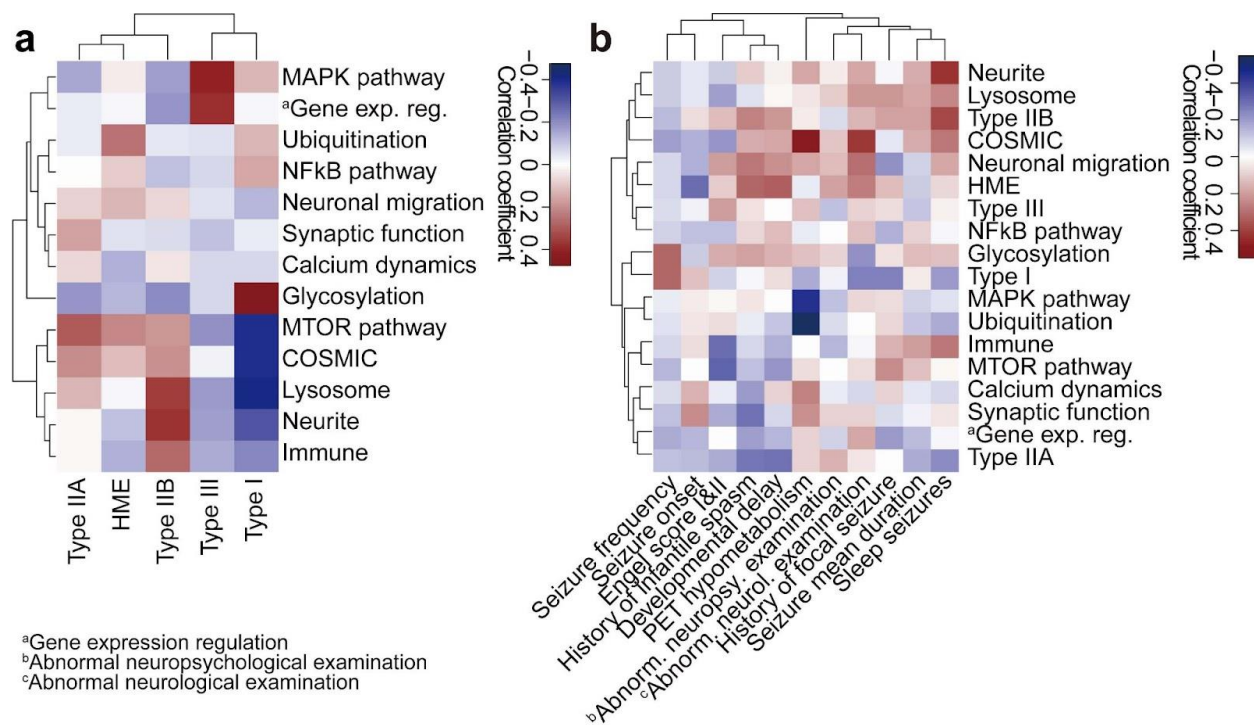

Figure 4. Clinical phenotypic outcomes correlate with genotype-based classifications in MCD. (a) Correlation heatmap for classification based on genetic information (y-axis) vs. International League Against Epilepsy (ILAE) classification based on histology (x-axis) using Pearson correlation. Shade: the value of Phi coefficient. Note Type IIA and HME are enriched with mTOR and Ubiquitination genes, while Type I is enriched in Glycosylation and depleted in MTOR and COSMIC genes. HME: hemimegalencephaly. (b) Correlation between classification based on genetic information and various clinical phenotypes. Shade: the value of Phi (binary data) or Pearson (continuous) correlation coefficient. For example, positron emission tomography (PET) hypometabolism is enriched in COSMIC genes and depleted in the MAPK pathway, whereas abnormal neurological examination is enriched in COSMIC genes. The whole dataset is in Supplementary Table 4.

722

723
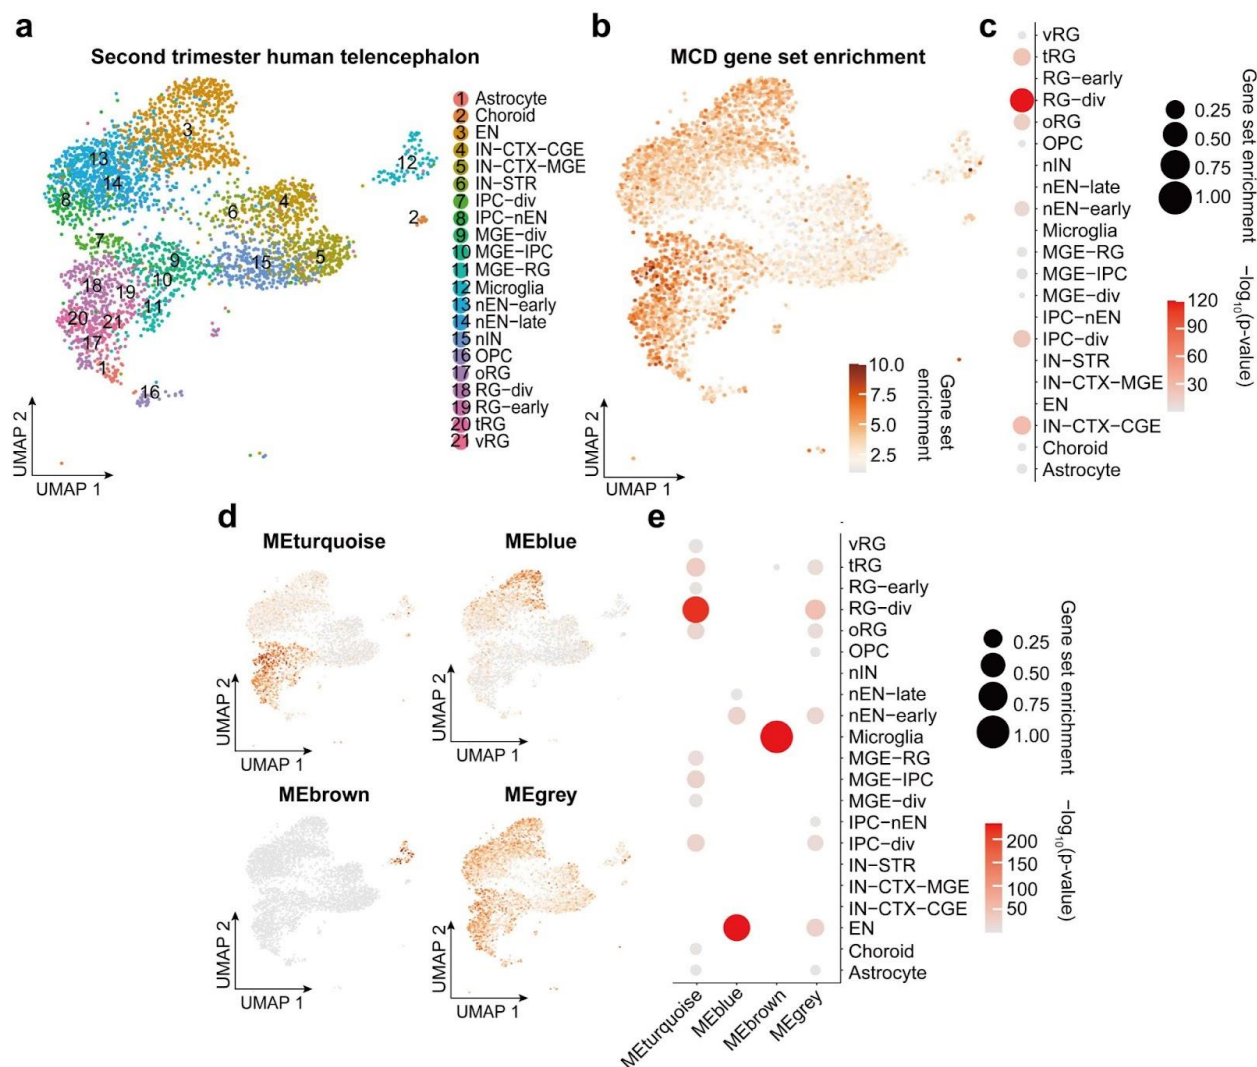

Figure 5. Single-nucleus transcriptomes reveal MCD gene enrichment in radial glia and excitatory neurons in the developing human cortex. (a) Uniform Manifold Approximation and Projection (UMAP) for single-nucleus transcriptome in 2nd-trimester fetal human telencephalon from a public dataset[41]. (b) UMAP enrichment patterns of an eigengene using MCD genes. Note enrichment for excitatory neurons and radial glia (dark brown). vRG: vertical radial glia, tRG: truncated radial glia, RG-div: dividing radial glia, oRG: outer radial glia, EN: excitatory neuron, nEN: newborn excitatory neuron, IPC: intermediate progenitor cell, STR: striatum, IN: interneuron, CTX: cortex, MGE: medial ganglionic eminence, CGE: central ganglionic eminence. (c) Quantification of enrichment of (b) based on cell types, showing enrichment for RG-div. (d) Four eigengenes decomposed from (b). (e) Quantification of enrichment of (d) based on cell types showing enrichment in dividing radial glia, microglia, and inhibitory cortical neurons from the medial ganglionic eminence (MGE).

20
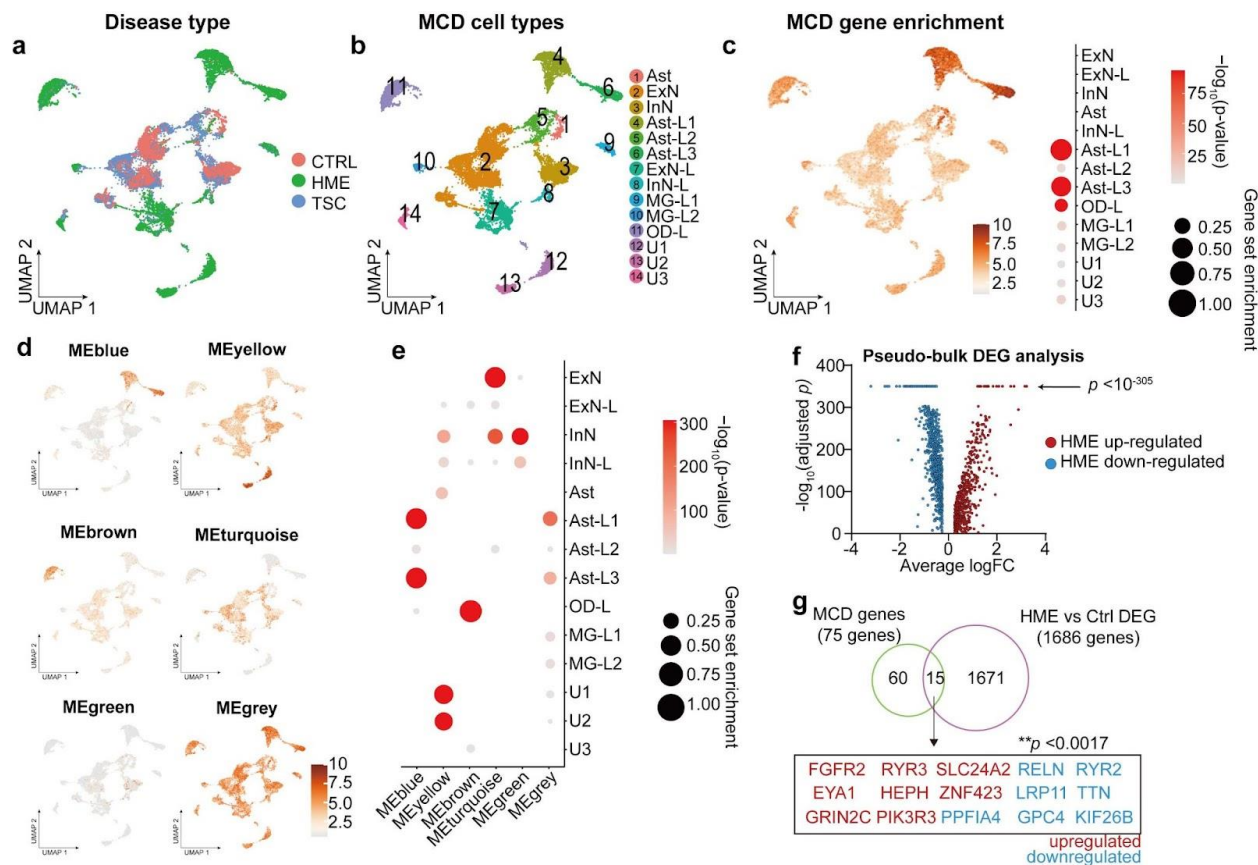

Figure 6. Single-nucleus transcriptomes showed MCD gene expression enriched in MCD-specific cell types. (a) UMAP for the single-nucleus transcriptome of 22067 nuclei from the cortical lesions of control (CTRL), hemimegalencephaly (HME), and tuberous sclerosis complex (TSC) brain. (b) Cell type classification. Ast: astrocyte, ExN: excitatory neuron, InN: inhibitory neuron, MG: microglia, OD: oligodendrocyte, U: unidentified. (c) The expression pattern of an eigengene made with all MCD genes and the quantification of enrichment based on cell types. (d) Six eigengenes decomposed from (c). (e) Quantification of the cell-type-specific enrichment in (d). (f) A volcano plot from DEG list of HME versus CTRL pseudo-bulk data. The genes having adjusted $p < 10^{-305}$ were pointed by the arrow. (g) The MCD genes overlap with DEGs of HME in contrast to controls. A permutation test (10,000 times) shows a very rare chance ($p < 0.0017$) to show this overlap in a random sampling of 1686 genes from 19909 protein-coding genes used in these DEGs. Red or blue coloring of gene names indicates upregulated or downregulated DEGs in HMEs compared to CTRLs, respectively.

Supplementary Table Descriptions

Supplementary Table 1. The cohort list and corresponding sequencing methods. The 327 cases are listed in each row and corresponding sequencing methods used for a given sample were described.

Supplementary Table 2. AmpliSeq primer pool designs (a) Ampliseq primer pool design used in phase 1. (b) Ampliseq primer pool design used in phase 3.

Supplementary Table 3. The summary of SNV calls across the three phases of genetic discovery. (a) 1811 raw calls derived from the combination of variant callers described in Extended Data Fig. 1. (b) 554 input SNV calls participated in TASeq quantification. (c) Validated brain somatic SNV calls from (b). (d) Annotation table of the genes listed in (c) based on GO terms.

Supplementary Table 4. The summary of phenotype and genotype information for the 'genetically solved' cases.

Supplementary Table 5. The summary table used for false discovery estimation.

773

774

775
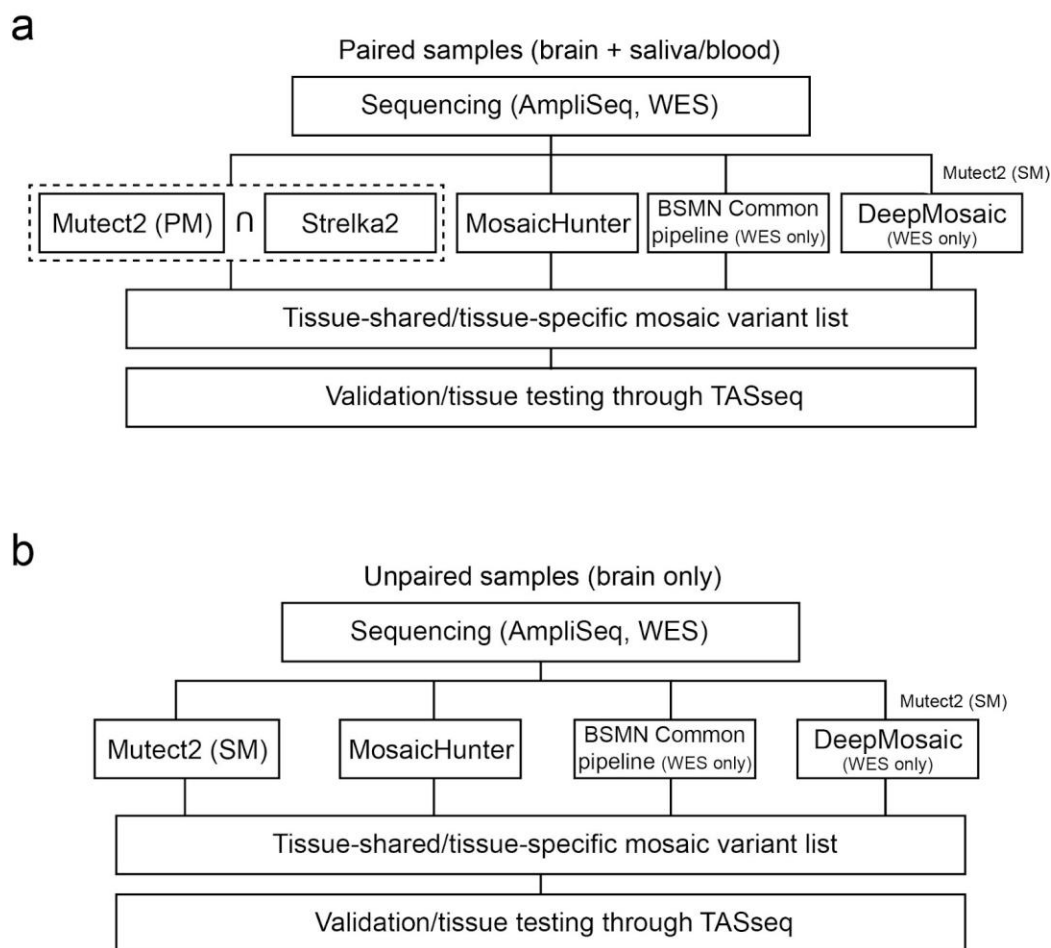

Extended Data Fig. 1 Bioinformatic pipeline to detect somatic SNVs in the MCD cohort. (a) The pipeline for paired samples. Notably, the dashed square indicates that the sharing variants between MuTect2 paired mode and Strelka2 were used for the downstream analysis. BSMN common pipeline and DeepMosaic were used only for WES datasets. The DeepMosaic input variants were generated by MuTect2 single mode. (b) The pipeline for unpaired samples. The pipeline is similar except that MuTect2 single mode without Strelka2 is used. PM: paired mode, SM: single mode.
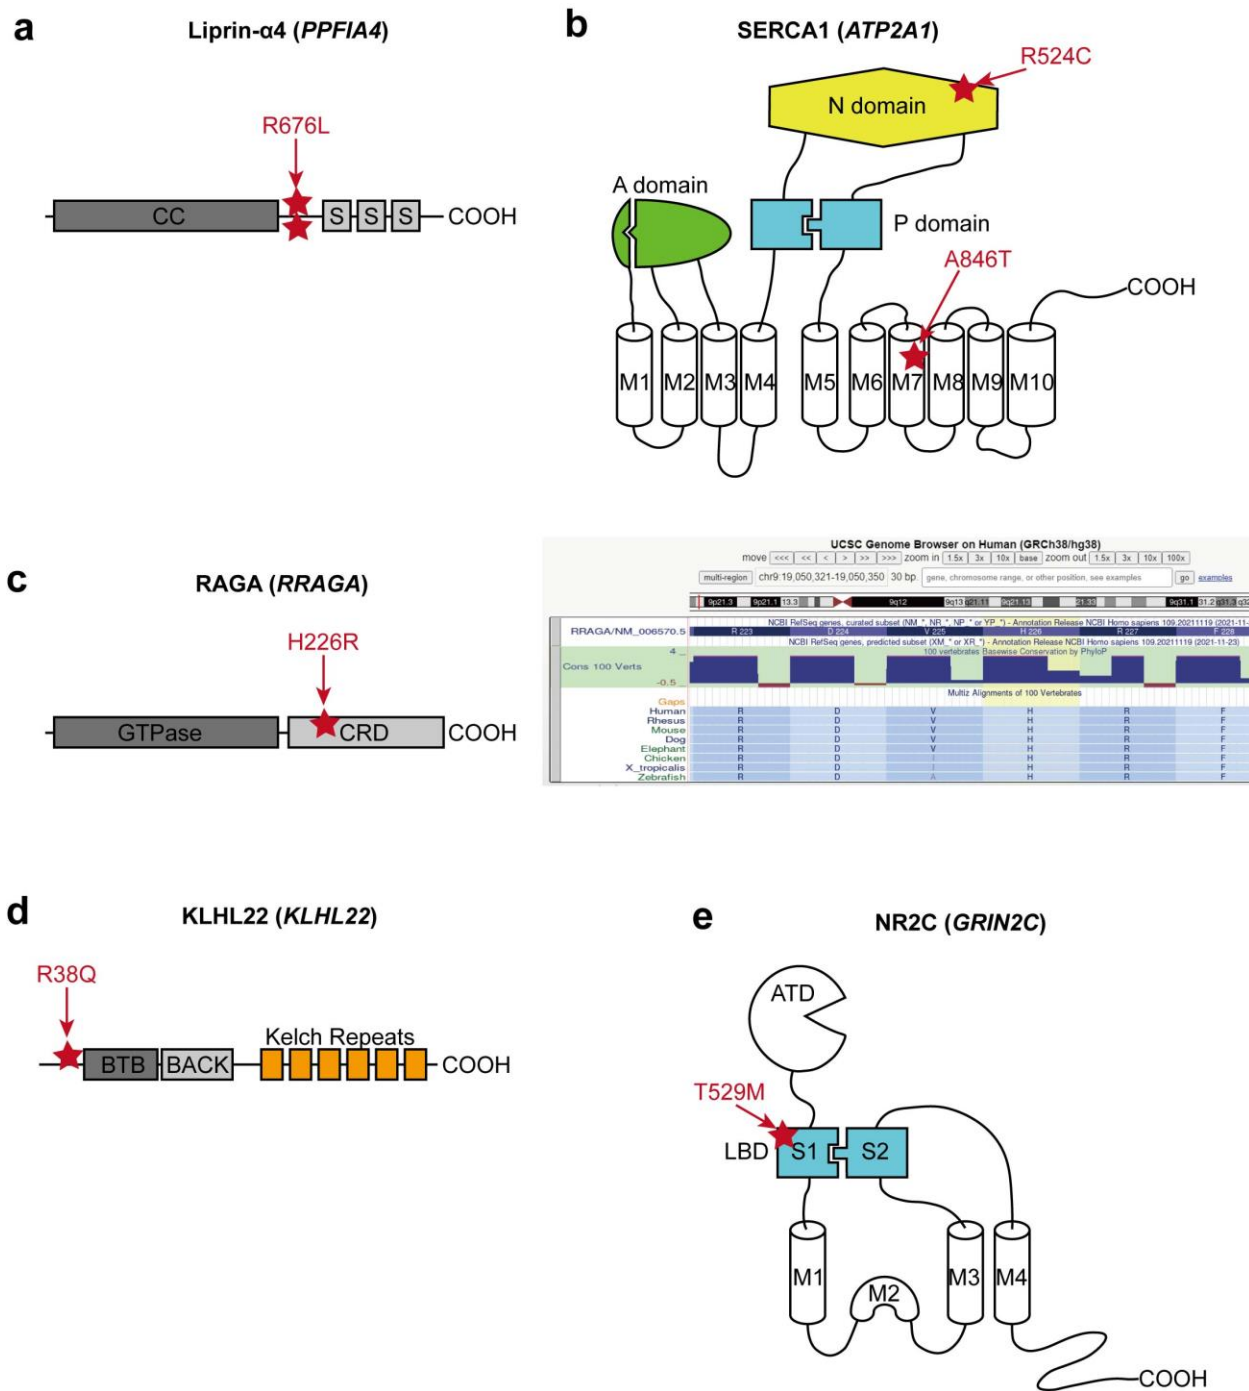

783

784

Extended Data Fig. 2 Mutational signature analysis through Mutalisk shows cell-division-related clock-like signatures in the MCD cohort. SBS5 (39.1%) and SBS1 (33%) are clock-like mutational signatures. SBS1 especially correlates with cell division and mitosis of stem cells.

24

Extended Data Fig. 3 The locations of the selected MCD variants. (a) The location of two recurrent variant calls is at the same position between the coiled-coil domain (CC) and the first SAM domain (S) of Liprin-α4. (b) Two different variants in SERCA1. p.R524C mutation is at the nucleotide ATP-binding (N) domain, whereas the pA846T variant is in the 7th transmembrane (M7) domain. A: Actuator domain, P: Phosphorylation domain, M: Transmembrane domain. (c) Left: The location of p.H226R variant in RAGA protein. GTPase: GTPase domain, CRD: C-terminal roadblock domain. Right: UCSC genome browser screenshot

800   describing that p.H226 is a conserved site across all vertebrates. (d) The location of p.R38Q
801   variant in the N-terminal region before BTB (Broad-Complex, Tramtrack, and Bric- à-brac)
802   domain of KLHL22. (e) A variant in the S1 domain of NR2C. S1 and S2 together make the
803   ligand-binding domain (LBD), the target of glutamate. ATD: Amino terminal domain.
804
**Extended Data Fig. 4 The ClueGO analysis using the MCD genes result identifies the biological processes and molecular pathways.** The main cluster is related to TOR signaling, regulation of cell-matrix adhesion, regulation of focal adhesion assembly, and artery morphogenesis. Notably, there are also isolated clusters that were not covered in previous studies, for example, cardiac muscle cell contraction, calcium ion import, and protein localization to the synapse. Term p-value with Bonferroni correction was reflected in node size (Large: $p < 0.0005$, medium: $p < 0.05$, small: $p < 0.1$).

**Extended Data Fig. 5 Cell-type identification by DEGs and known marker gene expression in the MCD snRNAseq dataset.** (a) MCD prefix was used for the clusters that have less than 25 % of control origin. (b) DEG analysis using FindAllMarker function in Seurat v4 package. The top 10 genes for each cluster were presented. Several notable genes helping to define major

28

818   cell types were labeled on the left side. Note that *FGFR3* and *PDGFRA* are up-regulated in Ast-
819   L1/3 and U1/2/3, respectively, implying that these genes can be the markers for MCD-dominant
820   clusters. (c) Selected markers for major cell types in the human cortex. *CUX1, CUX2* for upper
821   layer excitatory neuronal markers, SATB2 for layer 4 excitatory neuronal marker, *RORB,*
822   *FEZF2, BCL11B, FOXP2, ROBO2* for deep layer-specific markers, *GAD1, GAD2, DLX6, RELN*
823   for inhibitory neuronal markers, *GFAP, SLC1A2, SLC1A3, MMD2* for astrocyte markers, *PTPRC*
824   for the microglial marker, *OLIG1, OLIG2, MOBP, PLP1* for oligodendrocyte markers, *FGFR1,*
825   *FGFR2, FGFR3, PDGFRB, EGFR* for the selected GBM-enriched genes covering subsets of
826   MCD-enriched clusters.
827
Extended Data Fig. 6 The validation of the snRNAseq result from HME-6593 shows MCD dominant clusters are highly correlated with dysplastic cells in MCD. (a) H&E staining (left) and RNAscope (right) staining results in several MCD-dominant markers (*FGFR2, FGFR1, EGFR*) in the same formaldehyde-embedded-paraffin-fixed section. (b) H&E and RNAscope result in another section with different RNA probes (*FGFR3* and *PDGFRA*) enriched in MCD clusters. Dashed lines indicate blood vessels. White/black arrows are pointing to the dysplastic cells.
