Public exams may decrease anxiety and facilitate deeper conceptual thinking

Abstract:

Assessment methods across post-secondary STEM education are traditionally constrained by

logistics and likely contribute to the widespread inequities in STEM education outcomes. As part

of attempts to improve and diversify the methods used in assessment, the authors have developed

a flexible and low-tech style known as 'public exams' based in educational best practices. Public

exams attempt to involve students authentically into the process of assessment through the use of

pre-released portions of the exam. Through an initial mixed-methods research endeavor at a

closely-matched pair of a research-intensive university and a community college classroom, we

observe signals of positive impact from the public exam on student experiences. Public exams

appear to promote deeper thought, to direct students more efficiently to the core concepts in the

discipline, and may decrease student anxiety around exams. The public exam experience does

not show evidence for exacerbating gaps in exam outcomes for students from underrepresented

backgrounds. This evidence suggests that public exams are worth deeper investigation as an

evidence-based and effective assessment style.

Introduction:

High-stakes examination-based assessments (hereafter, exams) are a common and

widespread feature of postsecondary education (Stobart & Eggen, 2012). Whether used to give

formative feedback to students, to summatively assess students' knowledge, to create selection

barriers for capacity-constrained programs or careers, or simply to assign grades for external use,

these exams are complex structural elements that students must grapple with (Wideen et al.,

1997). Problematically, the educational practices used widely in college and universities are

often based in traditional routines and logistical concerns instead of evidence-based, student-

centered practices (Ambrose, 2010; Chase, 2020). Improving the practices in giving and taking

exams has the potential to improve the educational experience for a more diverse, deeper, and

more talented pool of future students (Intemann, 2009; Ralph et al., 2022).

In our own classrooms, we struggled to develop traditional exams that met student needs

well. The frictions and problematic points in our exams reappeared consistently in student

feedback and seemed to align with problems discussed in education literature. Within the highly

unequal power relationship between students and their STEM faculty, students have little to no

agency about their own assessment (Metevier et al., 2022). Students for whom college practices

are new (to them, or to their communities) are figuring out the 'rules of the game'; those rules

can be unpredictable and highly consequential (Canning et al., 2020). Multilingual learners in

monolingual classrooms face high-stakes challenges during an exam (Sibanda, 2021). Anxiety

around education can be exacerbated by exams and this anxiety tends to impact groups of

students unjustly (Cooper et al., 2018; Jenkins et al., 2021). Whether in stressed conversations or

anonymous evaluations, students repeatedly expressed problematic experiences with the exams

we constructed. The 'public exam' style that follows is the result of our efforts to design a better

system for delivering assessment challenges that was still a logistical fit within the constraints

and pressures of a full teaching load (Rossing & Lavitt, 2016).

Our solution is an interrelated set of evidence-based practices that we collectively

describe as the 'public exam' style. The traditional style for postsecondary STEM education is to

reveal assessment tasks to students during the exam itself (Roberts et al., 2021; Zhuang et al.,

2019). Ongoing work to redesign traditional exams includes efforts like competency-based

grading and other modes of producing formative and summative assessments in college STEM

(DeCoito & Estaiteyeh, 2022; Diegelman-Parente, 2011; Gao et al., 2020; Kitchen et al., 2006;

Lynd-Balta, 2006; Reynders et al., 2020; Stanger-Hall, 2012). In this work, we take a lens of

educative assessment to re-design our exams to be more educative and transparent. Educative

assessment can be summarized by saying that assessments have many purposes but the primary

among them should be as a tool for facilitating student learning (Buxton et al., 2013; Fink, 2003;

Jönsson, 2008; G. Wiggins, 1998, 2011). We chose this educative lens to ensure that our exams

were helping to meet our larger learning goals in a system where other goals like summative

grades are often strongly prioritized institutionally. Specifically, educative assessment suggests

that educators can create challenging exams for students that are useful practice for their careers

and lives such that teaching directly to these exams will be worthwhile (Erduran & Wooding,

2021). This increased focus on transparency in assessment is in contract with traditional methods

and likely to improve student outcomes (Felten & Finley, 2019; Harsma et al., 2021).

What is a public exam?

The public exam style is the result of our attempts to re-design exams to engender trust and

authentic engagement between students and instructors (Black & Wiliam, 2010). Throughout the

manuscript, we use the term "authentic involvement" to refer to stylistic elements of public

exams that address this overarching theme relating to trust (Brown, 2017). The three evidence-

based elements of public exams described below are frequently addressed throughout K-12

education and are useful in convincing students more often that the assessment process can work

for them (Darling-Hammond & Bransford, 2005; R. Keith. Sawyer, 2005; Zeichner et al., 2000).

These three stylistic elements of public exams are:

• Partial exam content is pre-released to students prior to the exam to deepen the cognitive

work that students perform during the actual assessment. This allows students to read

information about the nature of their tasks beforehand as well as to engage with

conceptually complex content that might take more time to comprehend than is typically

available for an exam (Margot & Kettler, 2019). Traditionally, exam content is often

encountered all at once in the context of the exam, and this rapid transmission of large

amounts of information constrains the asking of interesting and higher-order cognitive

exam questions due to the high cognitive load (Momsen et al., 2010; Sweller, 2010).

Throughout the manuscript, we use the term "Deepening thought" to refer to this first

element of public exams.

• The pre-release of exam content allows for communal improvement of the language used

on exams. By allowing students an opportunity to give feedback on exam formats and

wording through an optional editing activity, we leverage a larger group of motivated

student-editors to find and fix grammatically problematic pieces of the exam. Students

readily report these problems prior to the summative assessment, which is helpful to

faculty. These developing student-experts can also contribute to the writing of the exam

itself when faculty use public exams to assign editing or content creation work. This is

especially important because language barriers around exam content are hard to

disassociate from true struggles with content (Charity Hudley & Mallinson, 2017; Heath,

2000; B. Wiggins et al., 2020). Traditional exams are revealed late in the learning process

and cannot be co-created, so the onus of grammatical perfection falls on faculty who are

92  rarely as linguistically diverse as their student population (National Academies of Sciences,

93  2018a). Throughout the manuscript, we use the term "Language barriers" to refer to this

94  second element of public exams.

95  • Pre-released exam content allows instructors to amplify the importance of core concepts in

96  the course (Council, 2007). Instead of indirectly indicating core concepts through study

97  guides or practice exams or review sessions, the concepts and skills that are core to the

98  discipline are outlined in the context of the exam. We use the term 'core concepts' here to

99  broadly describe the content that instructors believe is more central to the practice of their

100  discipline (as in (McFarland & Michael, 2020). Traditional exams do this after the fact, at

101  which point the opportunity to direct optimal study practice is generally lost. Throughout

102  the manuscript, we use the term "Directing to core concepts" to refer to this third element

103  of public exams.

104 Because students and classrooms differ so greatly, the use of this public exam style is not

105 intended to be narrowly prescriptive. Instead, we offer this stylistic definition of public exams in

106 order to a) help guide instructors incrementally closer to more engaging assessments and b)

107 provide a basis for exploratory research to identify impacts on and benefits for postsecondary

108 students. A timeline comparison of a public exam and a traditional exam is shown in Figure 1.

110 *Fig 1. **Comparative timeline of traditional and public exams.***

Caption for Figure 1: Tasks to be completed are separated into those that are transparent to students and those that must necessarily be kept secret from students at the risk of giving away exam answers. For readers unfamiliar with traditional exams, the top timeline is offered as an approximation. The bottom timeline is an approximation of a public exam structure. The purpose of this figure is to illustrate the differences in increased transparency and opportunities to study from exam material in public exams.

As a simplified example, imagine an exam question in which the student is directed "For ten points, explain in three sentences or less how detoxification of human blood is performed by the cells in the liver." By pre-releasing the exam question for students but withholding only the word 'liver', the possible variants of the exam question are increased to include at least several organs. While providing the meta-information for the task as well as the framing of the topic area itself, this question maintains enough surprise to deeply examine student understanding. A further variant of a pre-released exam question might be: "For ten points, explain in three sentences or less how [withheld] of human blood is performed by the cells in the [withheld]." By withholding just a single additional word, students are now given direct information about both the method/scope of written assessment as well as tangible evidence that their understanding of processes impacting human blood will be crucial for demonstrating deep understanding of the topic. Other examples of public exam questions are presented in Figure 2.

*Fig 2. **Examples of public-style exam questions.***

Examples of public exam questions:

Public Version of 1) Three molecules are interacting with each other through the formation of three hydrogen bonds. Draw three possible hydrogen bonds with dashed lines. Make the relevant partial charges clear. The three molecules are water, alanine, and *[withheld]*.

Public Version of 2) How would platelet production change if *[change to the platelet system withheld]*?
A. Many fewer platelets would be produced
B. Many more platelets would be produced
C. The same number of platelets will be produced
D. *[answer choice withheld]*

Public Version of 3)

The calcium regulation system shown here is largely independent of control by the nervous system. What is one possible advantage of this?
A. *[Answer choice withheld]*
B. *[Answer choice withheld]*
C. *[Answer choice withheld]*
D. *[Answer choice withheld]*

Public Version of 4) In the fictitious prokaryote below, some of the genes on the single circular chromosome are shown along with their gene products. Central dogma transitions are shown in solid arrows, promoter sequences are indicated with a 'P' and a curved arrow, and protein interactions are shown by dashed arrows. The SercPlus operon is generally associated with the bacterial behavior observed when the bacteria has arrived at a new, rich food source. The Sercs channel facilitates diffusion of a wide range of nutrient molecules into the cell. Protein Q has a role in rapid cell crawling. This system functions in ways that are conceptually similar to well-studied parts of the lac operon in E. coli. *[Question withheld]*

Caption for Figure 2: For each of 4 exam questions, the pre-released version provided to students well before the exam is shown. In dashed insets are the changes made to the question for the actual version that students complete for course points. The purpose of this figure is to give examples of a few of the types of exam questions that can be used in public exams.

Research Framework and Questions:

Our goal in this work is to demonstrate if and how public exams may impact the experiences of

college students. Our methodology follows a design-based tradition in which education

interventions are implemented and researched dynamically and iteratively in parallel (Collins et

al., 2004). Design research is an appropriate choice because we continue are studying student-

centered systems in context (Sandoval, 2004). To explore our research questions, we apply

mixed quantitative and qualitative methods and attend to signals in the data that triangulate

similarly across multiple types of investigation (Denzin, 2012).

Our research questions are the following:

- In what ways do public exams impact the student experience?

149   o   Are these impacts negative or positive?

150   o   Are these experiences impacted by Language barriers, Directing to core concepts,

151   Deepening thought, and/or Authentic involvement?

•   Do public exams exacerbate grade inequities across demographic groups?

•   Do students dislike public exams?

•   Can public exams be applied across postsecondary education contexts?

Methods:

Research environments:

Research was conducted at both a research university (R1) and a community college

(CC) in the Pacific Northwest of the United States. Students were enrolled in lower-division

courses in Biology departments during Quarter 2 of 2021. The R1 course was taught for 300

students and the CC course was taught for 48 students from which populations of 292 and 32

participants, respectively, were included through IRB-approved consent processes (under

protocol #s STUDY00012237, ECIRB-20210512 and IRB-2020-0813). These courses were

chosen for consistency of general topic and level, for the large population in the R1 course which

allowed quantitative analysis of subgroups, and for institutional access to research. Students in

the R1/CC courses were 63%/59% non-white, 77%/66% registrar-identified female, 24%/20%

first-generation attending college, 12%/24% international and (at the R1) 31% identified as being

from historically underserved populations by the R1 university. Students in both courses

typically have interest in a wide range of career goals around healthcare, science, research and

business. Public exam techniques were used in both courses. Both the CC and R1 courses were

using public exams for the first time in those environments. In the large R1 course, students were

graded primarily on the basis of 5 total exams given every 2 weeks throughout the 10-week

quarter. In the smaller CC course, students completed a total of two exams that were written in

the public exam style.

Research flow:

This work was conducted using a design-based research methodology, which allows for

preliminary research findings to be used to guide the collection and analysis of subsequent data

in an iterative fashion (Collins et al., 2004). Examining human experiences in this methodology

is intended to be more rigorous than simple, self-reported data while allowing a greater breadth

of possible findings than quantitative experiments alone would observe. This methodology is a

good fit for education systems where iterative redesign and incremental improvement of human

experiences are the primary goals of research and implementation work (Sandoval, 2004).

Here, we used *qualitative interviews* to broadly assess the experiences of students taking

public exams around our three main research questions. Interviews were also used to assess

differences in the student experience between institutions. These interview findings refined our

analysis of a larger data set by *coding open-ended survey items*. In parallel to this qualitative and

mixed-method work, students in the R1 course took exams that used both public and traditional

questions to experimentally observe signals of inequity in exam outcomes. This *within-exam*

experimentation controls for student identity, instructor impact, classroom environment, and

content material in comparing data from public and traditional assessment questions. This

quantitative data collection and analysis is intended to cast a wide net for possible negative

impacts of public exams on student experiences. Any positive impacts of the public exam system

that are observed are likely to be conservative because of issues with first-time implementation

fidelity (in both R1 and CC courses) and incomplete application of the public exam system (in

the R1 course). *Student self-reported preferences* for exam style were collected for triangulating

with other types of data; this self-reported data may help to illuminate the presence of unknown

negative impacts of the intervention, but is not in itself convincing of positive impacts of the

intervention. The overall process of data collection is described below in Figure 3. The purpose

of collecting a wide range of types of data is to broadly investigate the possible outcomes from

this intervention and better understand the possible avenues for future, deeper research

investigations. Here we present the results of this initial design-based research study.

*Fig 3. **Data collection scheme.***

Caption for Figure 3: The purpose of this figure is to make clear when and in which class environment the data
were being collected.
208

Qualitative interviews:

Group and individual interviews were used to hear student experiences using grounded

ethnographic principles (Glaser & Strauss, 1968; Rubin, 2012) and with subject-centered and -

driven methodology from dialectical behavioral therapy (Linehan, 2018). Eleven interviews

totaled 488 minutes of recorded discourse with 20 participants. Student participants were

recruited to participate via random email to course lists. Data around the interviews at both sites

as well as all transcripts are available in Supplement 1.

During qualitative interviews, broad experiential opening questions were used to elicit a

broad spectrum of conversations around students' experiences (Cameron, 2005). Rather than

bringing in specific questions or prompts, the facilitator followed up with probing questions on

student-raised topics pertaining to our research questions (Rubin, 2012). Thematic representation

in anonymized transcripts saturated (Saunders et al., 2018) at the R1 site after 6 interviews.

Transcripts of qualitative interviews were initially analyzed by coding on four prevalent

themes drawn from our original research questions: 1) Language issues, 2) Directing to core

concepts, 3) Deepening thought, and 4) Authentic involvement. We decided to investigate these

four themes due to anecdotal discussions with many prior students. The new codes 5) Anxiety or

Confidence and 6) Collaboration emerged during iterative qualitative analysis of interviews with

students at the CC and R1 institutions, where students strongly expressed the importance of these

themes. Lastly, the code 7) "Not Related to the Public Exam System" was designed to capture

student experiences that were not part of the public exam system. The descriptive language

found in the coding tables was iteratively improved for clarity and to better match student

language. Transcripts were subsequently re-coded using this improved set of seven codes. The

final consensus coding table for interviews with exemplary quotes is available in Supplement 2.

Coding of open-ended survey items:

Open-ended survey items were used as a quantifiable source of qualitative data at scale. In a

participation-only study, all students at both sites were asked to answer the question: *"Did the*

style of exams in [this course] work for you? Why or Why not?". Cognitive testing for validity of

this question was performed with a separate group of students that were of the same age and

progression as students at the CC and R1 sites. Responses to the final version of this open-ended

survey question were collected and anonymized from 242 participants at the R1 site and 32

participants at the CC site.

Within the open-ended survey responses, the seven final codes were iteratively coded and

discussed and then coded for presence. Each code was also sub-coded as positive or negative

with regards to literature-based learning outcomes for students. This was not opinion-based

coding on the part of students, but rather researcher-based assessment of whether the practices or

experiences presented were positive or negative based on educational best practices as described

in national best-practices texts including How People Learn II (National Academies of Sciences,

2018b) and the biology-focused AAAS document Vision and Change (AAAS, 2011a). In other

words, these results were not coded for what students enjoyed or appreciated (see examples in-

text below) but rather for conditions in which learning is likely to be supported. Two researchers

independently coded 15% of the responses and achieved an acceptable interrater reliability score

of kappa = 0.88 (McHugh, 2012). One researcher coded the remaining responses.

For examples of the positive or negative coding, a student who indicated "*The public*

exam made it harder to know what I needed to know" would be coded into the category of

'Directing to core concepts' and as a 'Negative' impact, since confusion about core concepts is a

problematic distractor for learning across fields (Meyer, 2004; National Academies of Sciences,

2018b; R. Keith. Sawyer, 2005). If a student indicated that they "*hate public exams because they*

force me to think more deeply," then this would be coded as a 'Positive' impact within the theme

of 'Deepening thought', even though the student may not have enjoyed that aspect of the

learning challenge. Further examples and final codes are available in Supplement 3.

To determine if the prevalence of any codes was significantly impactful on student

experiences, we calculated the percent of students who provided feedback on each qualitative

theme of the public exam system in the open-ended survey items and whether that feedback was

positive or negative. To determine if there was a relationship between the type of feedback

students provided (i.e., about the public exam system or not) and the nature of that feedback (i.e.,

positive or negative), we conducted a series of Pearson's chi-square tests of independence for

each of the six codes of the public exam system as well as an aggregate of all six codes. A

control for statistical tests was needed that is more conservative than a simple 1:1 null ratio. We

used Code 7 ('Not related to the Public Exam System') as a control group, which is more

conservative than a simple control ratio like 1:1 and thus controls for the general tendency for

participants to report positive experiences more often than negative experiences. When a given

count in the contingency table was too small (i.e., less than five) to conduct a chi-square test, we

used a Fisher's exact test (Bower, 2003; McCrum-Gardner, 2008).

Within-exam experimentation:

Within the large R1 course, students completed five summative exams in which

assessment questions were a mix of traditional 'surprise' style exam questions for which they

had no pre-knowledge and other 'public' style exam questions for which students had exposure

to much of the information in the individual question well before the time of assessment. For this

course, all exam questions were written in multiple choice format. The relative amounts of

traditional or public exam questions changed throughout the course. Students began the quarter

with two exams that used the same distribution of multiple-choice exam questions: 15 public-

style exam questions and 10 traditional, surprise-style exam questions. Subsequent exams (in

response to student survey responses, see discussion) included 20 public-style exam questions

and 5 traditional, surprise-style exam questions. The purpose of this within-exam

experimentation is to collect well-controlled data that might lead to the observation of inequity in

this style of assessment rather than to prove any particular value of an assessment style. Because

the variation between assessment styles happens within each exam, this experimental design

controls for scientific topic areas, for student identities, and for the instructor among other

variables that are otherwise difficult to control.

Quantitative data collection and analysis:

Within the large R1 course, the following discrete data were collected for each participant:

College GPA, course grade, exam results for each question on each exam, scores for

participation-based assignments, completion or not of an exam editing activity, and (via the

university registrar) race/ethnicity, gender, international student status, first-generation in college

status, and inclusion in the university-assigned Education Opportunity Program (EOP). This last

categorization is particularly important to this work: the R1 institution defines "under-

advantaged" students as students identified as part of the EOP and these students hail from

educationally or economically disadvantaged backgrounds. Because this EOP categorization is

based on family income and other variables not typically represented in simpler demographic

statistics, we chose this measure before analysis as the single variable on which we would pre-

build models for analysis as has been used in other, similar work (Freeman et al., 2017; Wright et

al., 2016). All data collected in these ways are available in anonymized form in Supplement 4.

In order to determine if students performed differently on public or traditional exams, we

used a two-sample t-test to compare the total percentage of points students earned on all public

exam questions and all traditional exam questions throughout the term.

In order to determine whether there were differences in exam performance on each type

of exam question based on students' demographic characteristics, we used linear regression

models and included gender (male/female), EOP group of interest (yes/no), and overall GPA

(from the registrar on a 4-point scale) as predictors. (Example model: percent score on public

exam questions ~ gender + interest group + GPA.) Gender has been shown to affect student

exam performance (Odom et al., 2021) and students in our EOP group of interest have been

found to do worse than their peers on exams at this institution (Cooper et al., 2020). We

acknowledge that registrar data for gender that includes only male/female do not best represent

all individuals' gender identity and that not every person identifies in the gender binary (Cooper

et al., 2020), but we did not ask students to self-report their gender.

To examine potential demographic differences in students' self-reported preferences for

the proportion of each question type on an exam, after the second and third exams, we asked

students if they would prefer to have more public questions, fewer public questions, or keep the

same ratio of public to traditional questions for future exams. After the fourth exam, we asked

students if they would prefer more or fewer public questions with no neutral option. We

calculated the percentage of students who selected each option and assessed potential

demographic differences of students' preferences after the second and third exams using

multinomial regressions and using logistic regression for preferences after the fourth exam. We

again included gender (male/female), EOP group of interest (yes/no), and overall GPA (based on

registrar data on a 4-point scale) in our models. (Model for post-exam two and three preferences:

exam preference (more public/fewer public/same) ~ gender + interest group + GPA; model for

post-exam four preferences: exam preference (more public/fewer public) ~ gender + interest

group + GPA.)

Preceding each exam, students were given the opportunity to provide edits on the public

portion of the exam. This was an optional part of a required online assignment which students

were able to bypass and still receive full participation points. To investigate the extent to which

the experience of providing edits on the exams might correlate with their overall course grade,

we used a linear regression with the total number of exams for which the student provided edits,

EOP group of interest (yes/no), and overall GPA as the predictors in our model. (Model: course

grade ~ total edits + interest group + GPA.)

*Table 1. **Research questions and methods used in this study***

Research Question:	Research Method:	Participants (N)
In what ways do public exams impact the student experience	• Qualitative interviews	11 interviews with students of 488 total minutes or >65,000 words (20 students)
Are these experiences impacted by Language barriers, Directing to core concepts, Deepening thought, and/or Authentic involvement?	• Coding open-ended survey items	Open-ended responses coded from R1 (242) and CC (32) students
Do public exams exacerbate grade inequities across demographic groups?	• Within-exam experimentation • Quantitative data analysis	5 exams with mixed question types from R1 students (242)
Do students dislike public exams?	• Within-exam experimentation • Student self-reported preferences	3 post-exam surveys with multiple-choice responses from R1 students (242)
Can public exams be applied across postsecondary contexts?	• Qualitative interviews	20 students *(same as Row 1)*

338   *Caption for Table 1: The purpose of this table is to make clear the connections between multiple research questions*
339   *and the research methods used in combination to assess those questions. Participant statistics included for*
340   *comparisons of scope.*
341

Results:

Qualitative interviews:

Interview-based methods were used to guide the overall flow of research, and also to better understand whether public exams might be applicable to community college courses, which are generally smaller and less available to quantitative research, we undertook qualitative interviews in a closely-matched community college course. This CC course closely matched the R1 course in terms of topic, location, timeline, and the first-time use of the public exam style for the course. Our primary codes were evident in similar proportions, and student comments to interviewers brought up similar challenges and gains. No thematic signals appeared to us in one environment and not the other.

Coding of open-ended responses:

Students in the large R1 course answered a survey item: "*Did the style of exams in [the R1 course] work for you? Why or Why not?*". All coding data for open-ended survey items is available in Supplement 5. When compared with a conservative control group using Code 7 ('Not part of the public exam system'), we observed a strongly significant statistical signal for the overall positive impacts of public exams (Table 2, Row 1). No significance (positive or negative) was observed for student mentions of language barriers, authentic involvement in the process of assessment, or collaboration. Student experiences with 'Directing to core concepts' were significantly positive (p value = 0.0002). Student experiences with 'Deepening thought' and 'Anxiety or Confidence' were also significantly positive (p values = 0.004 and 0.0101, respectively). Positive or negative experiential impact showed no statistical difference for students in the EOP group. These data suggest that students' unprompted experiences with public

365   exams are predominantly positive, which correlates well with preference data described below.

366   These data also triangulate well with interview results noting that deeper cognitive work,

367   decreased anxiety, and more efficient directing to core concepts are likely outcomes of public

368   exams. These results of the quantitative analysis of open-ended coding are presented in Table 2.

370   *Table 2.* **Results of coding of open-ended survey items.**

	Signal Pos:Neg	Null Pos:Neg	χ^2 Test Statistic	*P value*
Overall Impacts of Public Exams	97:22	74:38	7.1547	0.0075
Language barriers	9:9	74:38	1.7353	0.1877
Authentic involvement	11:4	74:38	0.3152	0.5745
Collaboration	13:0	74:38	*Cannot run test with a zero result.* *Does not approach significance.*	
Directing to core concepts	55:5	74:38	13.6508	0.0002
Deepening thought	27:2	74:38	8.2834	0.0040
Anxiety	31:4	74:38	6.6150	0.0101
Results are different for students in underrepresented groups	24:9	19:15	2.0669	0.1505

Caption for Table 2: Instances of codes are tabulated from open-ended survey item responses from 242 students in
the R1 environment. In each entry for Signal (Column 2) and Null (Column 3) the occurrences are presented as
'PositiveInstances:NegativeInstances'. The Null ratio of codes used as a control is taken from all codes not related
to features of the public exam for the same population of students. Significance tests compare Signal ratios to Null
ratios (which are themselves conservatively more positive than 1:1) using a Chi-squared test statistic. The purpose
of this table is to show which codes were found to have statistically significant presence in students' unprompted
self-reported experiences, and whether those codes had an impact that is likely to be positive or negative on
learning.

Within-exam experimentation:

Comparisons of exam outcomes on mixed traditional/public exams were used to

quantitatively assess possible issues of equity. Student exam outcomes on public and traditional

exam questions were analyzed for two groups of students: a university-identified diverse group

of students in the Educational Opportunity Project (EOP), and the rest of the student population.

As shown in Figure 4, we observed in our model that all students performed better on public

exam questions compared to traditional exam questions (blue lines). Because of the differences

in learning processes between public and traditional exam questions, this difference in

performance is not evidence of learning differences between contents assessed in a given

method. We also observed the expected decrease in high-stakes exam scores across question

types for students from EOP underrepresented groups (red lines). The combination of these

trends was consistent for students in both EOP and non-EOP groups, giving no indication that

public exam questions resulted in increasing inequity.

*Fig 4. **Exam outcomes for traditional- and public-style exams.***

396   Caption for Figure 4: Color plots are separated by underserved Education Opportunity Project (EOP) group in
397   yellow and non-EOP (majority) group in purple. The EOP group is a university-defined amalgamation of
398   underserved identities that was chosen as a single, objective variable to collectively indicate students for whom
399   traditional postsecondary education outcomes has served them poorly. Significant differences were found in the
400   higher scores for students on public style exam questions as compared to traditional exam questions (indicated with
401   blue asterisks), although the difficulty or achievement on these exam questions cannot be directly compared as the

learning structures were different. Significant differences were found in exam scores between groups of students,
which is consistent with pernicious gaps in outcomes in postsecondary education (indicated with red asterisks). No
differences in the patterns of outcomes for traditional/public exam questions were found in either group of students,
which is consistent with public exams being similarly equitable compared to traditional exams. The purpose of this
figure is to display the outcomes of this experiment intended to observe any differences in equitable treatment of
students if they exist.
408

Student self-reported preferences:

In the large R1 course, students were asked about their preferences for public or

traditional exam questions. After experiencing two mixed exams with 15 public and 10

traditional questions each, 41% of students preferred to keep the same distribution for future

exams, 3% of students wanted more traditional questions, and 56% of students wanted future

exams to have a greater proportion of public-style questions. After listening to this student voice

and increasing the proportion of public questions for the following exam, students were surveyed

with the same options. After this exam with 20 public and 5 traditional questions, 67% of

students wanted to keep the increased 20:5 distribution while 6% wanted more traditional

questions and 24% wanted more than 20 of the 25 questions to be public. Course instructors kept

the 20:5 ratio for the next exam, and students after this exam were given only two options so as

to better understand the preferences of the majority of students. In this final survey prior to the

final exam, 15% of students wanted to decrease the number of public questions and 85% wanted

to increase it. Throughout these exams and the overall self-reported desire for more public exam

questions than traditional questions, there was no significant signal for a demographic basis on

which these preferences were made, nor was preference correlated with course grade outcomes.

Does editing of the exam impact students?

As part of the public exam, students were given the opportunity to suggest edits or

contributions to the public exam document itself. Edits suggested by students included

highlighting grammatical errors in the exam, suggesting improvements to the content text in the

exam, and suggesting creative additions to complete partial questions. Students who undertook

these optional, non-credit opportunities, when controlling for course grades and demographic

backgrounds, were significantly more likely to perform better in their overall course grade (p

value = 0.000402).

Discussion:

Here we discuss the results in light of our research questions, as well as future research questions

and limitations of this work.

In what ways do public exams impact the student experience?

Analysis of students' open-ended survey responses showed an overall significant and

positive impact of public exams on student experiences in a large STEM course. The positive

impact of public exams on student experiences was significant even when controlled against

other student responses in the same environment. They also triangulate well with themes from

interviews, self-reported preference surveys, and with anecdotal narratives from public exam

practitioners more widely.

'Directing students to core concepts' was significantly and positively significant, which

speaks directly to a consistent challenge for novice learners. While accepting the deluge of

information present in any fast-paced course, novice learners struggle to develop mental models

to organize incoming information (26). Modern courses typically offer an array of learning

materials to assist students in developing understanding of which pieces of information are core

to the discipline and which pieces of information are facts or ideas that simply reinforce the

concepts that an instructor feels are core to mastering the material in their course. Within the

public exam structure, students have early access to exam materials that are directly connected to

course points. Instead of deducing core concepts from lectures, assignments, study guides and

other indirect sources, students in a public exam course have the contextual clues to infer value

by placement (or not) on the actual assessment itself. In contrast, traditional exams typically hide

these valuable assessments until the moment of the exam itself. The significant, positive impact

of 'Directing to core concepts' on public exams may be a reflection of these benefits to learning.

As one R1 participant said:

"...they provide me with some direction on what to study a lot for. I think that

there's a lot of material that's covered in this course throughout the lectures,

and it would be hard to remember every single detail from the textbook, so I

think the guidance of the public questions really helps you to look back at that

specific part in your notes and/or the lecture to refresh your memory on what

you learned."

Many instructors are frequently confronted with, "What do I need to know for the exam?" from

students. Perhaps similar to some types of practice exams given before an exam (Crowther et al.,

2020), public exams help students to focus on key content instead of feeling overwhelmed.

'Deepening thought' was also found to be statistically significant and positively aligned

with learning in student experiences. The logistical constraints of exams can push instructors to a

'flattening' of thought; this problematic trend contributes to science being aligned with low-level

accumulation of simple facts (Crowe et al., 2008). It is possible that benefits from public exams

come from the increase in higher-order exam question (Anderson & Krathwohl, 2001; Barnett &

Francis, 2012; Lemons & Lemons, 2013), which was the intent of the designers but not assessed

in this study. The significant, positive benefits from the public exam style may be due to shifting

exam-provoked thought from a one-time performance into a longer and more collegial set of

learning cycles (Schwartz et al., 1999). Because students are less limited by the time needed to

read and comprehend a complex exam scenario, more interesting scenarios can be approached by

the instructor. Assessment materials transmit the values of the instructor into real terms (G.

Wiggins, 1998, 2011). Students reported being challenged by the public exam format to more in-

depth learning of a concept. In interviews, students realized that with the extra time to think

about and discuss exam questions, there was an expectation of exam responses that demonstrated

deeper thought and synthesis. For example, a CC student said:

"Personally I liked this type of exam a lot more. I didn't feel like I had to

memorize anything. More like I understood the concept and could be asked

questions about [it] from multiple angles. It helped learning with others as well

because when explaining to other people a certain topic, and they begin to

understand tells me that I understand the concept exceptionally well."

As more disciplines make calls for deeper critical thinking skills (AAAS, 2011b;

Halpern, 2001; McConnell et al., 2019; *Engage to Excel: Producing One Million*

Additional College Graduates with Degrees in Science, Technology, Engineering, and

Mathematics, 2012), it is possible the pre-release of exam material (as in (Crowther et

al., 2020) is a motivating factor in pushing students to do, share, and enjoy this deeper

thought.

Anxiety and Confidence around education (and more specifically exams) is a constant

and increasingly-pressing concern (Disability, 2017; Health, 2020). While this is well-studied in

STEM courses (Cooper et al., 2018; Downing et al., 2020; Schussler et al., 2021), it may be more

relevant instead to courses for which high-stakes exams are a primary feature (Brady et al., 2018;

Culler & Holahan, 1980; Harris et al., 2019); STEM courses generally meet this description

(Momsen et al., 2010). Learning is maximized at moderate levels of stress (Rudland et al., 2020),

but greater stress hampers learning and motivation and disproportionately impacts students from

groups traditionally underrepresented in the holders of college degrees (Lee et al., 2021; Medina,

2011; Misra & McKean, 2000; Vaidya & Mulgaonkar, 2007). There is some indication that this

current most-diverse and most-economically challenged generation of students in college are

also understandably the most over-stressed that have ever enrolled (Lederer & Hoban, 2020).

With less anxiety associated with the surprise of the exam, they were able to feel more confident

and prepared. A R1 student noted:

"... with the availability of the public exam I am able to study the possible

directions the questions might take. It reduces the amount of stress and anxiety I

usually get when I take exams, I feel more prepared."

Public exams may help students to alleviate some of their stress through some familiarity with

non-content information. Strategic points like where to focus effort and time can be usefully

discussed and digested at home. Shifting non-content mental effort out of the exam performance

time may explain why coding analysis shows better outcomes in public exams and would be in

line with prior research (Hacker et al., 2008; Pate et al., 2019). It is also possible that the steps

made towards exam transparency have a role to play, as signals of equitable behavior on the part

of powerful authorities may suggest to students that they need not worry about being caught in a

negative power-dynamic over some other disputed element within assessment (Bang & Medin,

2010; Bell et al., 2012; Fredricks et al., 2004).

Public exams include opportunities for students to authentically engage in the creation of

the assessment through edits and suggestions. Students who took advantage of these

opportunities also performed better in the class. Those edits are sparse among many exam

questions, and the changes suggested rarely alter content, so this trend is unlikely to be

explainable by gains on the specific question edited by the student. The statistical model used

controlled for demographics and for student course grade, so it is less likely that this is a self-

selection of which students choose to take on this extra task. If the correlation observed (p value

= 0.000402) indicates a causative relationship, then it may be explainable in one of three ways. It

might be that students who engage with the exam in this editorial mode are finding a new way to

engage with the material. By seeing the content from a different angle, one more closely aligned

with the perspective of the faculty instructor, they may find their own perspective on the content

to be broadened in useful ways. This is in line with learning theory about critical thinking skills

(Halpern, 2001). A second possibility is that engaging with assessment as a partner, even in a

temporary way, may help students to feel authentically involved in the process of assessment.

Affective impacts can improve learning (Dweck, 1986), so this specific observation would be in

line with learning theory. Lastly, it is possible that this result conflates students who did not

provide edits with students who never accessed the public exam materials (even after frequent

instructor guidance), which might contribute to their lower course grade. In the first two models,

the benefit to student learning would be valuable and further research will be required to better

understand how, for which students, and under what conditions this benefit is generated.

Do public exams exacerbate grade inequities across demographic groups?

Prerequisite to understanding more about the specific impacts of public exams, and as part

of feminist and anti-racist drives within education research, we want to ensure that public exams

do not contribute to the extant inequities in student outcomes within postsecondary education

(Museus et al., 2015). Those concerns are most pressing for assessments, which often represent a

gateway for student success at which inequities are both created and revealed. The primary goal

of our quantitative within-exam experimental design in a large R1 course was to help understand

if public exams are creating or exacerbating inequities for students from groups historically

marginalized in postsecondary education. Analysis of question-by-question exam outcomes in a

large course is our most likely opportunity to observe a signal of inequitable outcomes. Close

analysis of question-by-question outcomes make clear that these pernicious gaps in outcomes

exist beyond our research environment: Students from underrepresented groups are associated

with lower scores on both public and traditional exam questions. Clearly, improving outcomes

for all students will take much more than the use of public exams. Of particular importance for

our study is that outcome gaps are not exacerbated by public exams. In other words, the gaps

between public and traditional question outcomes are not different between groups of students or

exacerbated by this new exam style.

Do students dislike public exams?

Beyond these three emergent aspects of the student experience, student self-reported

preferences for exam style were strongly in favor of questions in the public exam style. These

positive preferences are not explainable by demographics or class success. It is not clear why

students prefer public exams from this study; it may be a preference for deeper thought, for more

directed practice, for the novelty of a new challenge, for their involvement in the assessment

process, or for the perception that pre-released exam information will make for an easier course

assessment (although the similar scoring averages between exam question types help students to

understand quickly that this is not the case). Further research will be needed to better understand

the parts of the public exam system that are preferred and how to maximize these elements

usefully. If these preference survey results can be taken at face value, then student preferences

for public exam questions are strong, are in accordance with findings from open-ended coding

and qualitative interview analysis, and are unlikely to indicate any widespread dislike of the

public exam style that might forewarn practitioners from attempting to implement it. From a lens

as a classroom instructor, is also encouraging to see a strong signal of preference for a style of

exam that requires more complex thinking.

Are public exams likely to be applicable across postsecondary contexts?

The results of qualitative research across two disparate types of institutions give early

evidence that public exams can fit in an array of environments. Analysis through iterative coding

of interview transcripts brought us to the conclusion that students in the two courses had similar

experiences with public exams. This is an initial attempt to explore the possible broad

application of public exams, and clearly more research will be required on a greater scale to

make similar conclusions. In the meantime, the outcomes of these analyses are consistent with

public exams being similarly applicable across these two institution types.

For example, a CC student noted that:

"we were able to sit down and start bouncing information off of each other and asking

different questions about the questions...just kinda sharing information right before the

exam and that just gave me so much confidence as to how much I know going into the

exam so"

This student suggests a deeper questioning style beyond memorization, and notes the affective

impact of deeper thought as well. A second CC participant mentioned:

"it helps more with like understanding but sometimes when you're panicking about an

exam you're like 'I don't want understanding ; I just wanna know' but at the same time

you do have to understand things...if we hadn't had the public exam I would have studied

all five of the chapters and had like less knowledge on each of the things and I don't feel

like I would have remembered the exact definition of phenotypic plasticity as well as like

when I saw the question and was like, I really do need to know this for the exam."

These three coded themes of Anxiety, Directing to core concepts and Deepening thought are

evident here and were strongly present in both environments. Weaker themes of collaboration,

language issues on exams, and authentic involvement with assessment were evident in both

environments but to a consistently lesser degree. While we did identify emergent themes in this

work, no thematic signals appeared to us in one institutional environment and not the other.

Redesigning assessments through a lens of educative assessment:

From the beginning, the development of the public exam style has prioritized educative

improvement over other outcomes and purposes of summative assessment (G. Wiggins, 1998).

The public exam style is educative in that it both informs and improves outcomes. Our initial

research here indicates that student behavior is informed by the different challenges to be more

focused on the core concepts of the material. Outcomes are improved, as best we can observe

through independent coding of student experiences, to facilitate deeper thought around

conceptual science material as well as doing so with less perceived anxiety around the

assessment process. Especially in light of continuing challenges in STEM fields to retain

students and to push those students beyond simple memorization, the educative capacity of our

choices around assessment style may become increasingly important.

Limitations of this study:

As an initial foray into research on public exams, this study has many limitations. The

design-based research model used in this study is likely to unearth important features of the

student educational experience. However, this model is not intended to prove that a particular

feature is more or less important than another, or to compare overall impacts of the student

experience on learning or career success. Future research, using longitudinal analysis and topical

challenges, will be important for assessing the overall impacts of the public exam intervention

beyond these initial analyses. Constructs like anxiety are treated as emergent themes; future

research should apply established theoretical frameworks around anxiety to make use of

established survey instruments that may be a good fit to better understand the ways in which and

extent to which public exams affect student anxiety. The core features of public exams are

examined as a unit, and more work will be required to understand if benefits can be achieved

modularly. Largely a single-course study, this analysis may be conflated by the specific

instructors or the environment of early 2021 (in itself, a unique time to be working in

postsecondary education during a pandemic). Education impacts tend to be relatively weak in

comparison to impact size of other fields, so it is possible that other important features have gone

unexamined for lack of analytic power in a single course of 300 students. This is especially true

for particular groups of students of historic importance, for whom numbers are smaller and

backgrounds unique to this particular study environment. Furthermore, the novelty of the public

exam style in post-secondary classrooms means that specific instruments for investigating

assessments on more traditional models were not available. Future research should involve

validation of specific instruments for assessing these learning cycles, such as those seen in

(Arikan et al., 2022; Chang et al., 2021; Hicks et al., 2017; Johnson et al., 2022; Reynders et al.,

2020). Perhaps most importantly, this study did not directly assess student learning but rather the

student experience. We hope that the benefits demonstrated, combined with positive anecdotal

reports on the strengthened student/instructor relationships in similar courses, motivate future

research to better understand how varied assessment styles can better serve the next generation of

students and improve on this work.

One salient criticism of public exams is that the process can be summarily characterized

as 'teaching to the test'. This pejorative has a long and well-deserved history in K-12 education,

especially in situations where externally-created assessments are linked to a motivation to

maximize scores for the purposes of accumulating outcome-linked resources (Jensen et al., 2014;

Ravitch, 2020). We propose that many college and university exams are fundamentally different

in that the instructors have wide purview to create exactly the kinds of assessments that reflect

the values, skills and content needed in modern pursuits. In other words, professors can create

the kinds of exams for which 'teaching to the exam' is inherently valuable for students (Jensen et

al., 2014; G. Wiggins, 1998). We hope that public exams are a useful way to do this.

Considerations for interested practitioners:

Transitioning from traditional exams to a public exam style is a low-tech strategy to

employ several best practices likely to improve student learning. Instructors found that they

could make simple changes to the exams or exam blueprints that they were already using by

withholding some of the information. In many cases these adjustments shorten the exam by

augmenting the higher cognitive exam questions and allowing students to discuss core concepts

in more detail because students had more time to reflect on the question. Additionally, instructors

were receiving meaningful feedback from students during the editing process of their new public

exam that improved their exam questions. Importantly, instructors do not need to adjust the

entire exam to the public method. Instructors can slowly transition to a greater percentage of the

exam being publicly available over the quarter or semester or academic year. Anecdotally,

students were excited to be part of the public exam process and a new assessment strategy that

they participated in.

Postsecondary instructors have numerous choices when designing exams (Gezer-

Templeton et al., 2017; Hodges, 2004; Knierim et al., 2015; Wieman et al., 2014). For those who

want to take up public exams as a style of assessment, we suggest adjusting a small number of

questions on an upcoming exam into a public-like format as depicted in Figure 2. This helps

create a positive feedback loop for instructor design and feedback from students, and it also helps

to avoid taking on an unsustainable overhaul of all assessment in one course. In our experience,

instructors who take up a few challenging pre-released exam questions a) quickly develop the

communication needed for students to understand how and why to access the materials, and b)

invariably lead to greater use of these methods in future assessments. Discussing an exam draft

with someone experienced in public exams is especially useful; please do write to the

corresponding author if this would be useful for you. An earlier, deeper, non-peer-reviewed

logistical discussion of public exams within the field of molecular biology may be of interest to

practitioners (B. L. Wiggins, 2019).

We have proposed that public exams may be a strategy to address some of the anxiety

associated with taking exams. It is important to note that the adjustment period as instructors

implement a new exam style may be longer for some students compared to others. Some

strategies that could facilitate a smoother transition are starting off with lower stakes quizzes or

exams, practice assignments or quizzes, or setting up student groups where students can support

each other. Although we did not find support for "Collaboration" in the quantitative coding

analysis, at least some students recognized the advantage in collaboration when preparing for the

exam. A R1 student described this by saying:

"I have noticed that it only works for me when I work with other people in

study sessions. I try to study on my own. I have a more difficult time

understanding the material, which is something quite new to me since I am

used to studying on my own. But overall I like it."

Students may not have recognized that collaboration was not only acceptable but highly

encouraged, often not utilizing that strategy until later exams. As a CC participant explained:

"I loved the second exam because I was able to meet up with others outside of

the classroom to go over a couple different concepts before the exam."

Emphasizing and encouraging collaboration as a strategy for student success on the exam, may

be another way the instructor can facilitate the transition from a more traditional exam model.

Conclusion:

We analyzed the impacts of public exams in STEM courses. Our mixed-methods design

research shows that students find significant positive impacts on their experiences. Those

impacts are largely focused on improving the direction of students to core concepts, the

deepening of thought in the assessment process, and helping students to manage anxiety. The

public exam method is likely to be similarly equitable to traditional methods and potentially

applicable across institutional contexts without exacerbating issues of educational equity. We

present this work in the spirit of improving assessment for all students as a core feature of

critical, high-quality education.

Acknowledgments:

This work was funded by the generosity of a private, independent research gift from CourseHero,

without which none of this research would have been possible. Participants and their data are all

protected by Institutional Review Boards under #s STUDY00012237 (University of

Washington), ECIRB-20210512 (Edmonds Community College) and IRB-2020-0813 (Oregon

State University). We appreciate the efforts and contributions of Greg Crowther, Deb Donovan,

Kelly Hennessey, Lori Kayes, Devon Quick, Christine Savolainen, Mandy Schivell, Katie

Simons, Shelley Stromholt, Jeannette Takashima, Liz Warfield, and Seth Wiggins. C.A.B was

Data collection in Spring quarter of 2021:

Examples of public exam questions:

Public Version of 1) Three molecules are interacting with each other through the formation of three hydrogen bonds. Draw three possible hydrogen bonds with dashed lines. Make the relevant partial charges clear.
The three molecules are water, alanine, and *[withheld]*.

water

alanine

[molecule withheld]

On the final version of #1:

[withheld]   *acetic acid*

[molecule withheld]   Changed to:

H_3C O   OH

Public Version of 2) How would platelet production change if *[change to the platelet system withheld]*?
A. Many fewer platelets would be produced
B. Many more platelets would be produced
C. The same number of platelets will be produced
D. *[answer choice withheld]*

On the final version of #2:

[change to the platelet system withheld]

[answer choice withheld]

Changed to:

if TPO was degraded rapidly

Platelets would be produced, but they will not be functional

Public Version of 3)

Dietary Calcium

The calcium regulation system shown here is largely independent of control by the nervous system. What is one possible advantage of this?
A.   *[Answer choice withheld]*
B.   *[Answer choice withheld]*
C.   *[Answer choice withheld]*
D.   *[Answer choice withheld]*

On the final version of #3:
'Answer choice withheld's became:
A. Bones do not have much contact with other kinds of cells besides osteoblasts and osteoclasts
B. Neurons can only increase the action of another cell, so they would be useless when calcium is high
C. Bone density can be independent of calcium levels
D. Neurons rely on calcium, so they may not be reliable effectors when calcium is low

Public Version of 4) In the fictitious prokaryote below, some of the genes on the single circular chromosome are shown along with their gene products. Central dogma transitions are shown in solid arrows, promoter sequences are indicated with a 'P' and a curved arrow, and protein interactions are shown by dashed arrows. The SercPlus operon is generally associated with the bacterial behavior observed when the bacteria has arrived at a new, rich food source. The Serc1 channel facilitates diffusion of a wide range of nutrient molecules into the cell. Protein Q has a role in rapid cell crawling. This system functions in ways that are conceptually similar to well-studied parts of the lac operon in E. coli. *[Question withheld]*

On the final version of #4:
[Question withheld] changed to:
Design or diagram a reasonable way in which the G1 checkpoint would interact with this system to ensure that the cell will not enter S-phase while the cell is rapidly crawling. Be specific about which molecules are interacting, and in what ways.
