Short Title – Transcription factor reprogramming in the cochlea

1 **ABSTRACT**

2 Reprogramming of the cochlea with hair cell-specific transcription factors such as ATOH1 has been proposed
3 as a potential therapeutic strategy for hearing loss. ATOH1 expression in the developing cochlea can efficiently
4 induce hair cell regeneration but the efficiency of hair cell reprogramming declines rapidly as the cochlea
5 matures. We developed Cre-inducible mice to compare hair cell reprogramming with ATOH1 alone or in
6 combination with two other hair cell transcription factors, GF11 and POU4F3. In newborn mice, all transcription
7 factor combinations tested produced large numbers of cells with the morphology of hair cells and rudimentary
8 mechanotransduction properties. However, one week later, only a combination of ATOH1, GF11 and POU4F3
9 could reprogram non-sensory cells of the cochlea to a hair cell fate, and these new cells were less mature than
.0 cells generated by reprogramming one week earlier. We used scRNA-seq and combined scRNA-seq and
.1 ATAC-seq to suggest at least two impediments to hair cell reprogramming in older animals. First, hair cell gene
.2 loci become less epigenetically accessible in non-sensory cells of the cochlea with increasing age. Second,
.3 signaling from hair cells to supporting cells, including Notch signaling, can prevent reprogramming of many
.4 supporting cells to hair cells, even with three hair cell transcription factors. Our results shed light on the
.5 molecular barriers that must be overcome to promote hair cell regeneration in the adult cochlea.

1 INTRODUCTION

2 Hearing loss is a widespread public health issue affecting hundreds of millions of people worldwide.
3 Hearing loss can be treated with cochlear implants or hearing aids but biological restoration of cochlear
4 structure and function is not currently possible. Hearing is mediated by mechanosensitive hair cells in the
5 organ of Corti, and loss or damage to these cells results in sensorineural hearing loss. Although mammals are
6 only capable of very modest spontaneous hair cell regeneration in the balance organs (Bramhall, et al., 2014;
7 Cox, et al., 2014; Golub, et al., 2012; Kawamoto, et al., 2009; Ogata, et al., 1999; Kelley, et al., 1995; Rubel, et
8 al., 1995; Forge, et al., 1993), the cochlea lack this regenerative capability. This is in not the case in lower
9 vertebrates. Robust turnover of hair cells is seen in the balance organs of many non-mammalian vertebrates
10 (Lanford, et al., 1996; Popper and Hoxter, 1990; Jørgensen and Mathiesen, 1988; Corwin, 1981). Impressive
11 structural and functional recovery can also be achieved in the hearing organs of non-mammalian vertebrates
12 following the killing of hair cells (Roberson, et al., 2004; Baird, et al., 2000; Cotanche, 1999; Adler and
13 Raphael, 1996; Roberson, et al., 1996; Niemiec, et al., 1994; Raphael, 1993; Corwin and Cotanche, 1988;
14 Ryals and Rubel, 1988). In these cases, supporting cells lying adjacent to hair cells can re-enter the cell cycle
15 and trans-differentiate to generate new hair cells. These findings have prompted efforts to promote the
16 regeneration of mammalian hair cells through genetic and pharmacological manipulations.

17 The basic helix-loop-helix transcription factor ATOH1 is both necessary and sufficient for hair cell
18 development and survival (Cai, et al., 2013; Chonko, et al., 2013; Driver, et al., 2013; Pan, et al., 2012; Woods,
19 et al., 2004; Bermingham, 1999). *In vitro* studies using explants of the mammalian cochlea or inner ear balance
20 organs showed that overexpression of ATOH1 can reprogram non-sensory cells of the inner ear into hair cell-
21 like cells (Jen, et al., 2019; Shou, et al., 2003; Zheng and Gao, 2000). Adenoviral expression of *Atoh1* in the
22 cochlea of guinea pigs deafened with ototoxic drugs shows a variable and partial restoration of hearing after
23 the lesion (Izumikawa, et al., 2005). *In vivo* studies employing neonatal transgenic mice showed that cells of
24 the greater epithelial ridge (GER) that lie next to the organ of Corti, and some supporting cells could be
25 reprogrammed to hair cell-like cells with the ectopic expression of *Atoh1* alone (Kelly, et al., 2012; Liu, et al.,
26 2012). However, the hair cell reprogramming ability of ATOH1 declines rapidly with age (Kelly, et al., 2012; Liu,
27 et al., 2012), suggesting a need for additional transcription factors to promote hair cell reprogramming in older

1 animals. Moreover, cochleae where the auditory epithelium has degenerated further to state lacking hair cell
2 and supporting cells (known as the flat epithelium; (Izumikawa, et al., 2008) do not respond to *Atoh1* over-
3 expression, further indicating the need for a more complex combinatorial approach.

4 Several transcription factors have been tested in combination with ATOH1 for their hair cell
5 reprogramming potential (reviewed by (Iyer and Groves, 2021). GF11 and POU4F3 are two hair cell-specific
6 transcription factors expressed downstream of ATOH1 during development that has been implicated in hair cell
7 survival and function (Masuda, et al., 2011; Hertzano, et al., 2004; Wallis, 2003; Xiang, et al., 1998; Xiang, et
8 al., 1997). Adenoviral delivery of ATOH1 and GF11 to adult mice in which hair cells were ablated promoted
9 regeneration through supporting cell transdifferentiation at a higher efficiency than ATOH1 alone (Lee, et al.,
10 2020). Similarly, transgenic over-expression of combinations of ATOH1, GATA3, and POU4F3 reprogrammed
11 adult supporting cells into hair cell-like cells with improved efficiency (Walters, et al., 2017). A combination of
12 ATOH1, GF11, and POU4F3 reprogrammed embryonic stem cells and chick otic epithelial cells *in vitro* to cells
13 that expressed several hair cell genes, and showed key hair cell features (Costa, et al., 2015). The co-
14 overexpression of these three factors *in vivo* can also reprogram neonatal Lgr5+ supporting cells into hair cell-
15 like cells more efficiently than ATOH1 alone (Chen, et al., 2021). Finally, the addition of SIX1 to the three factor
16 cocktail was able to reprogram adult mouse tail-tip fibroblasts into hair cell-like cells which have some
17 epigenetic and transcriptional characteristics of hair cells, as well as transduction channel protein expression,
and hair cell-like electrophysiological properties (Menendez, et al., 2020).

9 Recent studies have shown that one reason for the inability of cochlear supporting cells to convert to
10 hair cells is that the chromatin surrounding hair cell genes becomes progressively less accessible as the ear
11 matures (Tao, et al., 2021; Jen, et al., 2019). The use of multiple hair cell transcription factors to reprogram
12 supporting cells into hair cells may enhance the accessibility of hair cell loci in supporting cells, and recent
13 evidence suggests that some hair cell transcription factors such as POU4F3 can do so in the developing
14 cochlea by acting as pioneer factors (Yu, et al., 2021). However, the question of whether combinations of
15 multiple transcription factors simply improve the efficiency of hair cell reprogramming, or whether they can also
16 improve the fidelity of hair cell reprogramming by activating a larger number of hair cell genes is currently
17 unknown.

1 In this study, we sought to address this question by comparing the reprogramming potential of three
2 transcription factor combinations – ATOH1 alone, ATOH1 + GF11, and ATOH1 + GF11 + POU4F3 - in the
3 mouse cochlea. We generated three transgenic mouse lines in which the transcription factor combinations
4 were expressed from the ROSA26 locus in a Cre-dependent fashion. We found that ATOH1 alone is sufficient
5 to reprogram neonatal non-sensory cells of the greater epithelial ridge into a mosaic of large numbers of hair
6 cell-like cells that are surrounded by GLAST-positive supporting cell-like cells. The reprogrammed hair cells
7 resembled inner hair cells and possessed stereocilia and some mechanotransduction properties. At these
8 young ages, additional transcription factors do not enhance the number of new hair cells generated by ATOH1,
9 nor do they increase the number of hair cells genes expressed in these reprogrammed cells, determined by
10 single-cell RNA-seq. However, we show that after the first postnatal week, the overexpression of GF11 and
11 POU4F3 is necessary to enhance the hair cell reprogramming ability of ATOH1 in 8-day old supporting cells.
12 We also show that some supporting cell populations remain refractory to reprogramming even with three
13 transcription factors, likely due to the action of the reprogramming factors being blocked by Notch signaling
14 delivered by the endogenous hair cells. By simultaneously comparing the transcriptome and chromatin
15 accessibility of cochlear cells at birth and 1 week of age using single cell multi-omic approaches, we showed
16 that hair cell loci become progressively less accessible in supporting cells and non-sensory cells of the cochlea
17 during the first postnatal week. Our work provides the first mechanistic analysis of hair cell reprogramming and
18 reveals some of the epigenetic and cell signaling obstacles that will need to be overcome in a therapeutic
19 context in the mature inner ear.

20

1 RESULTS

2 **Hair cell transcription factors promote highly efficient reprogramming of non-sensory cochlear tissue** 3 **into hair cell-like cells in the neonatal mouse**

4 To directly compare the efficiency of different transcription factor combinations in hair cell
5 reprogramming, we targeted them to the *Rosa26* locus using a modified *Ai3* targeting vector containing a
6 transcriptional stop cassette flanked by loxP sites (Madisen, et al., 2010). We used three different hair cell
7 transcription factor combinations: ATOH1 alone, GFI1 & ATOH1, and GFI1, ATOH1 & POU4F3 (Figure 1A).
8 Individual transcription factor coding regions were separated by a GSG-T2A self-cleaving peptide sequence to
9 ensure comparable transcription factor expression levels (Tang, et al., 2009). We were able to achieve correct
0 targeting efficiency to the *Rosa26* locus of approximately 80% by co-electroporating our targeting vectors with
1 a plasmid expressing Cas9 and a sgRNA targeting the *Rosa26* locus between the two homology arms. This
2 high efficiency allowed us to obtain correctly targeted ES cell clones with multiple constructs in single
3 electroporation. We verified the expression of the transcription factor proteins by culturing the mouse ES cell
4 lines used to generate founders for the three targeted mouse lines in the presence of membrane-permeable
5 TAT-Cre protein, followed by western blotting (Figure 1 – Supplementary Figure 1A).

6 We targeted overexpression of the three-hair cell transcription factor combinations to the greater
7 epithelial ridge (GER) and supporting cells of the neonatal mouse organ of Corti using *Sox9-CreER* transgenic
8 mice (Figure 1B; (Kopp, et al., 2011). We confirmed GER and supporting cell-specific targeting with this mouse
9 line by administering tamoxifen to one-day-old (P1) *Sox9-CreER; RosaEGFP (Ai3)* mice and analyzing their
0 cochleae a week later (P8; Figure 1C). The pattern of recombination in GER cells and apical turn supporting
1 cells corresponded to the normal expression of SOX9 protein at this age, revealed by EGFP expression and
2 the absence of recombination in hair cells (Figure 1 – Supplementary Figure 1B). All three *Rosa26*-targeted
3 mouse lines were bred with *Sox9-CreER* to obtain experimental mice harboring both alleles. For the remainder
4 of the manuscript, we will refer to mice carrying the *Sox9-CreER* allele and the *Rosa26*-targeted transcription
5 factor combinations as Rosa-A, Rosa-GA, and Rosa-GAP (Figure 1B). We activated each combination of
6 transcription factors in the GER and supporting cells by injecting tamoxifen at P1 and analyzing mice one week
7 later.

1 We immunostained the 8-day-old reprogrammed cochleae for the hair cell marker Myosin VIIA and the
2 presence of actin-rich hair bundles with fluorescently-labeled phalloidin. We observed efficient reprogramming
3 of GER cells into hair cell-like cells (Figure 1D), with large numbers of reprogrammed Myosin VIIA+/phalloidin+
4 cells throughout the GER, extending from the neural edge of the organ of Corti to the interdental cell region
5 (Figure 1D). These ectopic cells could survive in the GER until at least 15 days after birth (Figure 1 –
6 Supplementary Figure 2). Reprogrammed hair cells were present in similar numbers throughout the basal-
7 apical axis of the cochlea, with an average of 300 reprogrammed hair cells per 200 μ m, compared to an
8 average of 28 inner hair cells and 90 outer hair cells in a corresponding 200 μ m length of the organ of Corti. We
9 did not observe significant differences in reprogrammed hair cell numbers between the three transcription
0 factor combinations at this age (Figure 1E). We characterized the P8 reprogrammed hair cell-like cells by
1 immunostaining for known hair cell and supporting cell markers (Figure 2A). The reprogrammed cells in the
2 GER expressed VGLUT3, a known vesicular transport protein expressed in inner hair cells (Obholzer, et al.,
3 2008; Ruel, et al., 2008) (Figure 2A). The reprogrammed cells did not express Prestin, a motor protein specific
4 to outer hair cells which is necessary for their electromotility and their contribution to cochlear amplification and
5 tuning (Zheng, et al., 2000). The reprogrammed hair cell-like cells in the GER received innervation from
6 auditory afferents, labeled with the TuJ1 antibody to β III-tubulin. The hair cell-like cells also stained with
7 antibodies to the CTBP2 transcription factor, which also recognizes Ribeye, a major component of ribbon
8 synapses formed between afferent neurons and hair cells (Sheets, et al., 2011).

9 To further characterize the hair cell-like cells, we used scanning electron microscopy to assess the
0 morphology of reprogrammed hair cell stereocilia and compared it to that of endogenous hair cells. Under all
1 three reprogramming conditions, reprogrammed hair cells throughout the GER had stereocilia-like protrusions
2 from their apical surfaces, possessing a staircase-like arrangement of hair bundles that appeared similar to
3 control hair cells of the same age (Figure 2B). To determine the presence of mechanotransduction channel
4 activity, we incubated explants of our P8 cochleae with the styryl dye FM 1-43, which permeates transduction
5 channels. Hair cells mature in a basal-apical gradient along the cochlear duct, and between P6 and P7, all hair
6 cells in the cochlea have matured to the point where they are permeable to FM1-43 dye (Lelli, et al., 2009).
7 Reprogrammed hair cells in the GER in all three conditions took up the FM 1-43 dye within 10 seconds (Figure
8 2B), although the degree of labeling of the reprogrammed cells in the GER was significantly fainter than the

1 endogenous hair cells visible in the organ of Corti. In sum, we established that under all three combinations of
2 hair cell transcription factors, we generated large numbers of reprogrammed inner hair cell-like cells that are
3 innervated, are morphologically similar to endogenous hair cells, show ribbon synapse formation, and possess
4 some mechanotransduction channel activity.

5 To test if cell proliferation played a role in the generation of the reprogrammed hair cells in the GER, we
6 assayed cell proliferation in the reprogrammed cochleae using EdU incorporation. Experimental and control
7 animals were injected with tamoxifen at P1 to initiate transcription factor overexpression, followed by EdU
8 injections (50mg/kg body weight) twice every other day until P8. We observed that cell proliferation occurred
9 only in the spiral ganglion region and not in the organ of Corti of experimental or control animals, and none of
10 the reprogrammed hair cells in the GER were labeled by EdU (Figure 2 – Supplementary Figure 1). These data
11 suggest that the vast majority of the reprogrammed hair cells we observe in the GER are generated by direct
12 non-mitotic reprogramming, rather than by proliferation.

13 **scRNA-seq analysis reveals that cochlear reprogramming in newborn mice generates new hair cells** 14 **that are similar to their endogenous counterparts**

15 Our data suggested that the gross phenotype of the reprogrammed hair cell-like in neonatal mice
16 resembled wild type hair cells, and did not vary significantly between the three reprogramming conditions. To
17 determine whether unique transcriptional changes occurred in response to the three reprogramming
18 conditions, we performed single-cell RNA-sequencing analysis of the reprogrammed cells. We bred the *Sox9-*
19 *CreER* mice to the *Ai9 Rosa-tdTomato* reporter line and further bred these to the three *Rosa26* conditional
20 overexpression lines (Figure 3A) to obtain our experimental mice, where one *ROSA26* allele carried a
21 *tdTomato* reporter, and the other *ROSA26* allele carried one of the three reprogramming cassettes. These
22 mice were injected with tamoxifen at P1 and *tdTomato*-positive cochlear cells were purified by FACS at P8
23 (Figure 3A) and used to generate scRNA-seq libraries using the 10xGenomics Chromium platform.

24 The cell clustering pattern observed after the integration of cells from all four genotypes allowed us to
25 identify expected cell-type-specific clusters based on transcriptomic data from previous studies (Kolla, et al.,
26 2020). Sensory and non-sensory cells of the cochlear duct, including hair cells, supporting cells, greater
27 epithelial ridge cells, cells of the stria vascularis, and glial cells were all identified in the clustering (Figure 3B).

1 Examples of marker genes used to validate cluster identification on the basis of their expression in the hair cell
2 and lateral GER clusters is shown in Figure 3 – Supplementary Figure 1. Our clustering analysis confirmed the
3 results obtained by staining with cell type-specific markers: we saw a reduction in cells of the GER (particularly
4 lateral GER) but a significant increase in the numbers of hair cells in the three reprogrammed conditions
5 compared to control mice (Figure 3C). Other cochlear cell types that were identified during this analysis are
6 indicated in the diagram in Figure 3D. We performed a gene ontology analysis (GO- Biological process) to
7 ascertain the morphological and functional characteristics of these reprogrammed hair cells. We identified 496
8 genes significantly expressed genes in the reprogrammed hair cells across all three overexpression conditions
9 (cut off p-value < $1.00E^{-25}$) which were used as input for gene ontology analysis. The top GO hits included
0 genes for sensory perception of sound (GO: 0007605, 27 genes, $p=1.40E^{-13}$), inner ear morphogenesis (GO:
1 0042472, 12 genes, $p=5.70E^{-04}$), auditory receptor cell differentiation (GO: 0042491, 7 genes, $p=5.70E^{-04}$),
2 cilium morphogenesis (GO:0060271,17 genes, $p=7.50E^{-04}$) and cell projection organization (GO:0030030,16
3 genes, $p=7.50E^{-04}$; Figure 3E). Together, our data suggest that reprogrammed hair cells possess many
4 morphological and transcriptional characteristics similar to endogenous inner hair cells. However, they also
5 show that at this age, the addition of Gfi1 and Pou4f3 does not improve the morphology of the reprogrammed
6 hair cells, nor a more complete complement of hair cell genes expressed in the reprogrammed cells.

7 **Overexpression of GF11 and POU4F3 enhances the hair cell reprogramming ability of ATOH1 in the** 8 **mouse cochlea at older ages**

9 Our data show that all three transcription factor combinations have similar hair cell reprogramming
0 potential in the neonatal mouse cochlea. Previous overexpression studies have shown that the reprogramming
1 efficiency of ATOH1 declines with increasing age (Kelly, et al., 2012; Liu, et al., 2012). We next explored the *in*
2 *vivo* reprogramming potential of our transcription factor combinations in older animals. Employing the same
3 experimental mouse breeding scheme as described above, we overexpressed the three transcription factor
4 combinations (ATOH1, GF11 & ATOH1 and GF11, ATOH1 & POU4F3) in the GER and organ of Corti, including
5 all supporting cells, again using *Sox9-CreER* mice (Figure 4A). We confirmed correct and efficient
6 recombination in GER and supporting cells by administering tamoxifen in one week old (P8) *Sox9-CreER*;
7 *RosaEGFP* mice and analyzing GFP reporter expression by immunostaining a week later (P15; Figure 4B).

1 Between P7 and P15, parts of the GER undergo remodeling through thyroid hormone-dependent apoptosis
2 and are replaced by cuboidal inner sulcus cells (Peeters et al., 2015). By P15 several rows of SOX9+ GER
3 cells remain on the lateral edge of the inner sulcus adjacent to the organ of Corti. These are still targeted
4 correctly by *Sox9-CreER* mice (Figure 4 – Supplementary Figure 1A).

5 We compared overexpression of the three transcription factor combinations by giving tamoxifen at P8
6 to Rosa-A, Rosa-GA, and Rosa-GAP mice harboring the *Sox9-CreER* allele to target the GER and supporting
7 cells. Analysis of the mice a week later (P15) with the hair cell markers Myosin VIIA and phalloidin revealed
8 that reprogrammed hair cells were significantly higher in the Rosa-GAP condition (average GAP
9 reprogrammed hair cells – 55, Inner hair cells- 31, Outer hair cells – 95 per 200µm length of the organ of Corti;
10 Figure 4D). These new hair cells continued to survive until at least P29 and showed increasing organization of
11 phalloidin-stained hair bundles with increasing age (Figure 4 – Supplementary Figure 1B). Immunostaining of
12 the reprogrammed cells revealed that, unlike the younger reprogrammed cells, P15 reprogrammed hair cells in
13 the Rosa26-GAP condition did not express the inner hair cell marker VGLUT3 (Figure 5A). These
14 reprogrammed hair cells did, however, show evidence of innervation based on staining with TuJ1 antibody,
15 and formed ribbon synapses based on positive staining for CTBP2 (Figure 5A). We used scanning electron
16 microscopy (SEM) to assess the morphology of reprogrammed hair cell stereocilia across all three conditions.
Low power images showed the presence of sparse reprogrammed hair cells in the ATOH1 and GF11+ATOH1
overexpression conditions which did not stain for any hair cell markers other than Myosin VIIA (Figure 5B).
Higher magnification SEM images at 50,000X revealed that individual hair cell stereocilia of reprogrammed hair
cells in all three conditions were immature compared to endogenous hair cells and the P1 reprogrammed hair
cells we observed at P8. Many of the ectopic cells possessed kinocilia but the stereocilia did not exhibit a
staircase-like structure and still contained many side links between individual stereocilia, indicating their
immature state (Figure 5B). Together, we established that all three overexpression conditions are capable of
producing reprogrammed hair cell-like cells at P15, but the Rosa26-GAP cocktail is significantly more efficient
at producing new hair cells. Nevertheless, these reprogrammed hair cells created between P8 and P15 are
less mature than those derived from reprogramming neonatal cells between P1 and P8..

1 To determine whether the hair cells generated by overexpression of ATOH1, GFI1, and POU4F3
2 expressed more elements of the hair cell gene regulatory network, we repeated the scRNA-seq analysis
3 described above on our three mouse lines, applying tamoxifen at day 8 and sorting and analyzing cells at P15
4 (Figure 6A). The genotype-integrated cell clustering pattern obtained allowed us to identify expected cell-type-
5 specific clusters based on marker expression data from prior studies (Ranum, et al., 2019). We identified
6 multiple cell types in the clustering, including glial cells, hair cells, supporting cells, cells of the stria vascularis,
7 spiral limbus, and interdental cells (Figure 6B). Examples of marker genes used to validate cluster identification
8 on the basis of their expression in the hair cell and supporting cell clusters is shown in Figure 6 –
9 Supplementary Figure 1. Initial clustering analysis confirmed our earlier findings that the number of
0 reprogrammed hair cells obtained in response to overexpression of GAP factors is greater than the small
1 number of hair cells seen with GFI1 + ATOH1 or ATOH1 alone (Figure 6C). Other cochlear cell types identified
2 in the analysis are indicated in the organ of Corti diagram using identical color coding to the UMAP plots
3 (Figure 6D).

4 To elucidate the characteristics of the reprogrammed hair cells, we identified a list of 200 significantly
5 expressed genes in hair cells obtained from each of the three overexpression conditions (cut off p-value <
6 $1.00E^{-15}$). We performed a gene ontology analysis to ascertain the overall characteristics of these
7 reprogrammed hair cells and look for possible differences (Figure 6E). The top GO terms included genes for
8 cell projection (GO:0042995), cytoskeleton (GO:0005856), cilium (GO:0005929) - Cellular component, Cell
9 projection organization (GO: 0030030) - Biological process, calcium ion binding (GO: 0005509), calmodulin-
0 binding (GO: 0005516) - Molecular function. Taken together, we have shown that hair cells obtained from all
1 three overexpression conditions are transcriptionally similar and possess immature hair cell-like features.
2 However, although the Rosa26-GAP reprogramming mice generate more hair cells, their transcriptional profile
3 did not differ significantly from hair cells observed in ROSA-A or ROSA-GA conditions, suggesting that the
4 additional reprogramming factors increase the efficiency, but not the fidelity of hair cell reprogramming.

5 **Hair cell reprogramming of the greater epithelial ridge generates a mosaic of hair cells and supporting**
6 **cells through activation of Notch signaling**

1 A consistent observation in our reprogramming experiments conducted between P1-P8 and P8-P15
2 was that some supporting cells of the organ of Corti – the Deiters’ cells and pillar cells – did not respond to the
3 reprogramming factors by expressing hair cell proteins such as Myosin VIIA and did not exhibit any
4 morphological changes indicating they were transforming into hair cells. We confirmed these results - obtained
5 with *Sox9-CreER* mice - using a second Cre line, the *Lfng-CreER* line that causes efficient recombination in all
6 supporting cell types in the organ of Corti (Basch, et al., 2016b). Under all three reprogramming conditions at
7 both stages (P1-P8 and P8-P15), we consistently failed to see conversion of Deiters’ cells or pillar cells into
8 Myosin VIIA+ hair cells (Figure 7 – Supplementary Figure 1).

9 Signals from hair cells, particularly the Notch signaling pathway, are known to promote and stabilize
10 supporting cell fate during development (Basch, et al., 2016b; Woods, et al., 2004) and induce supporting cell
11 fate in the presence of ectopic hair cells (Kelly, et al., 2012; Woods, et al., 2004). Two types of supporting cells
12 lie adjacent to inner hair cells: inner phalangeal and inner border cells. Both supporting cell types express the
13 GLAST glutamate-aspartate-transporter, which plays a role in the uptake of neurotransmitters by inner hair cell
14 ribbon synapses (Glowatzki, et al., 2006). PROX1 is a marker unique to pillar and Deiters’ cells of the outer
15 hair cell region, which is expressed until the second week of age (Bermingham-McDonogh, et al., 2006).
16 Finally, all supporting cell types in the neonatal cochlea express the transcription factor SOX2. To determine if
reprogrammed inner hair cell-like cells could promote the formation of supporting cell types normally
associated with inner hair cells, we immunostained cochleae reprogrammed from P1-P8 for the supporting cell
markers GLAST, PROX1, and SOX2. We found that cells in the reprogrammed GER lying beneath the
reprogrammed Myosin VIIA+ hair cells expressed GLAST and SOX2 protein, but not PROX1 (Figure 7A). This
suggested the reprogrammed hair cells were able to promote the formation of inner phalangeal cell and border
cell-like cells from the GER, even though these cells were also expressing the reprogramming factor
combinations. We observed approximately equal numbers of supporting cells in the presence of all three
transcription factor combinations, suggesting that even the presence of ATOH1, GF11, and POU4F3 in GER
cells was not sufficient to prevent them from forming supporting cell-like cells when apposed to reprogrammed
hair cells.

1 We analyzed our single-cell RNA sequencing data to identify differences in the type of GLAST+
2 supporting cell-like cells obtained in each condition by comparing them to wild-type (WT) inner
3 phalangeal/border cells. Our genotype-based cell clustering data showed a significant increase in the inner
4 phalangeal and border cell clusters between control and induced conditions (Figure 3C). A differential gene
5 expression analysis for supporting cells in Rosa26-A vs WT, Rosa26-GA vs WT, and Rosa26-GAP vs WT
6 indicated a common pattern of up- and downregulated genes (Figure 7B). *Cryab*, *Ccnd1*, *Rcn1*, and *Hes5* were
7 upregulated in all three cases. *Cryab*, is a known heat shock protein with otoprotective effects during stress
8 response and *Ccnd1*, is a cell cycle gene that is downregulated with the increasing maturity of supporting cells
9 (Sadler, et al., 2020; Erni, et al., 2019; Laine, et al., 2010). *Hes5* is a Notch-responsive gene that is expressed
10 in Deiters' cells and pillar cells but not inner phalangeal and border cells at birth (Tateya, et al., 2011;
11 Doetzlhofer, et al., 2009). Its expression in the reprogrammed GLAST positive cells is likely a response to
12 active Notch signaling induced by the ectopic hair cells to maintain supporting cell identity (Wang et al., 2010).
13 We next examined known Notch pathway genes by performing a differential gene expression analysis between
14 the reprogrammed GLAST+ supporting cells and reprogrammed hair cells at P8. We observed the
15 upregulation of Notch-receiving genes (*Lfng*, *Notch1*, and *Hes1*) in the reprogrammed supporting cells and hair
16 cell-specific (*Dll3*, *Jag2*, and *Dlk2*) Notch ligand genes in the reprogrammed hair cells (Figure 7C). This
17 suggests that transcription factor reprogramming is capable of reconstituting the Notch signaling interactions
18 between hair cells and supporting cells, and that these interactions are sufficient to repress the action of the
19 three reprogramming transcription factors in the ectopically-induced supporting cells.

20 We repeated our supporting cell experiments by activating reprogramming at P8 and analyzing at P15.
21 We saw evidence for the presence of ectopic GLAST+, SOX2+ supporting cell-like cells adjacent to
22 reprogrammed hair cells in the Rosa26-GAP condition alone (Figure 8A). EdU injections given every second
23 day from P8 to P15 showed that none of the reprogrammed hair cells or supporting cells were generated by
24 proliferation. (Figure 8 – Supplementary Figure 1). We examined our scRNA-seq data to determine the degree
25 to which supporting cells alter their transcriptomes in response to the three different reprogramming
26 combinations. We performed a differential gene expression analysis of all P15 supporting cells compared to
27 their wild-type counterparts to analyze transcriptomic changes in response to each of the three transcription
28 factor cocktails. The most significant up and down-regulated genes are highlighted (Figure 8B), and include

1 Notch pathway-associated genes like *Mfng*, *Ccnd1*, *Hes5*, and *Dlk2*. In parallel to this, we also observed
2 downregulation of many supporting cell genes such as *Ttll3*, *Rorb*, *Scd1*, *Scnn1b*, *Hhat1*, *Washc2* in addition to
3 *Caecam16*. A complete description of these differentially expressed gene functions and their cell type-specific
4 expression – extracted from the gEAR database (www.umgear.org; (Orvis, et al., 2021) is given in Figure 8 –
5 Supplementary Tables 1 and 2.

6 **Multi-omic analysis of the cochlea reveals hair cell loci become less epigenetically accessible in** 7 **supporting cells and GER cells between postnatal days 1 and 8**

8 The data described above suggest that both GER and supporting cells of the cochlea become more
9 resistant to transcription factor reprogramming into hair cells during the first postnatal week. To determine if
10 changes in the epigenetic accessibility of hair cell gene loci was partly responsible for this change, we used
11 scMultiome to simultaneously profile gene expression and chromatin accessibility at the single cell level for
12 each cell type of the cochlea in wild type day 1 and day 8 mice. We were able to identify most hair cell and
13 supporting cell types of the organ of Corti as well as cells of the GER by clustering based on scRNA-seq,
14 scATAC-seq and using “weighted-nearest neighbor” analysis (WNN; Hao, et al., 2021) which gave the clearest
15 separation of cochlear cell types (Figure 9A). We extracted ATAC-seq profiles from 1627 distal regulatory
16 elements associated with hair cell genes and generated heat maps to show the accessibility of these elements
17 in GER cells and inner phalangeal cells and border cells in day 1 and day 8 cochlear tissue (Figure 9B). 498
18 elements showed comparable accessibility in these cell populations at both ages. However, 972 elements
19 were significantly more accessible in the three cell populations at day 1 compared to day 8. A small number of
20 distal elements (157) appeared to be somewhat more accessible in GER cells at day 8 compared to day 1.
21 Examples of traces from some hair cell loci are shown in Figure 9C. *Hes6*, *Myo3b* and *Pou4f3* all showed
22 reduced accessibility at day 8 in distal or intergenic regulatory elements at older ages. These results also
23 provided a simple mechanistic explanation for why our three reprogramming mice - Rosa-A, Rosa-GA and
24 Rosa-GAP – were all equally capable of generating reprogrammed hair cells in neonatal mice. At P1, our multi-
25 omic analysis shows that the *Pou4f3* locus is epigenetically accessible in cells of the GER. We could identify
26 accessible peaks with ATOH1 binding sites in this locus (Figure 9 – Supplementary Figure 1B and C),
27 suggesting that activation of ATOH1 in the GER at this age could also induce expression of POU4F3.

1 Accordingly, we found that expression of ATOH1 alone induced POU4F3 protein throughout the GER with 3
2 days after tamoxifen addition (Figure 9 – Supplementary Figure 1A). However, in 8 day old mice, the *Pou4f3*
3 locus was significantly less accessible in GER cells (Figure 9 – Supplementary Figure 1B), suggesting that
4 ATOH1 alone would not be sufficient to activate these factors in GER cells. As expected, we saw no evidence
5 for induction of POU4F3 protein when ATOH1 was activated in Rosa-A mice at P8 and POU4F3 analyzed by
6 immunostaining at P11 (Figure 9 – Supplementary Figure 1A).

1 DISCUSSION

2 ATOH1 is the first transcription factor to be expressed in differentiating hair cells and is sufficient to
3 generate large numbers of new hair cell-like cells when ectopically expressed in non-sensory regions of the
4 embryonic or neonatal mouse cochlea (Kelly, et al., 2012; Liu, et al., 2012). However, its ability to reprogram
5 these non-sensory cells to a hair cell fate declines in the first postnatal week, prompting attempts to augment
6 its reprogramming activity with combinations of other hair cell transcription factors (Lee, et al., 2020;
7 Menendez, et al., 2020; Yamashita, et al., 2018; Walters, et al., 2017; Costa, et al., 2015). Here, we show that
8 the co-expression of ATOH1 with two other hair cell transcription factors, GF11 and POU4F3, in Rosa-GAP
9 mice can increase the efficiency of hair cell reprogramming in older animals compared to ATOH1 alone or
10 GF11 + ATOH1. However, the hair cells generated by reprogramming at 8 days of age- even with three hair cell
11 transcription factors - are significantly less mature than those generated by reprogramming at postnatal day 1.
12 By analyzing the epigenetic landscape of the cochlea over the first two postnatal weeks, we suggest that
13 reprogramming with multiple transcription factors is better able to access the hair cell differentiation gene
14 regulatory network, but that additional interventions may be necessary to produce mature and fully functional
15 hair cells.

16 By targeting different transcription factor combinations to the same locus – *Rosa26* (Figure 1A) – we
17 were able to directly compare the reprogramming ability of three hair cell transcription factor combinations
18 without the confounds of variable expression levels caused by different transgene copy numbers or integration
19 sites. Our results show that in newborn mice, activation of the reprogramming cocktails – ATOH1, ATOH1 +
20 GF11, and ATOH1 + GF11 + POU4F3 - can produce equally large numbers of new inner hair cell-like cells in
21 the greater epithelial ridge that receive neuronal input, form ribbon synapses, form immature stereocilia
22 resembling those of endogenous hair cells at this age, and exhibit rudimentary mechanotransduction
23 properties as shown by FM1-43 uptake (Figure 1 and 2). Moreover, these new hair cell-like cells can survive in
24 the transformed greater epithelial ridge for at least two weeks, overriding the process of GER remodeling via
25 apoptosis which occurs during normal cochlear development in mammals (Figure 1 – Supplementary Figure
26 2). Consistent with the similar morphological and functional properties of these reprogrammed cells, we found
27 no significant differences in the transcriptomes of the reprogrammed hair cell-like cells produced by the three

1 transcription factor combinations when induced at P1 and analyzed a week later (Figure 3). The simplest
2 explanation for these results is that the *Gfi1* and *Pou4f3* genes are direct transcriptional targets of ATOH1 (Yu,
3 et al., 2021; Ikeda, et al., 2015; Hertzano, et al., 2004), and thus activation of either ATOH1 alone (or GF11 +
4 ATOH1) would result in the activation of all three transcription factors, together with other transcriptional
5 effectors of the hair cell gene regulatory network. In support of this idea, we observe precocious induction of
6 POU4F3 protein in GER cells several days after the expression of ATOH1 in Rosa-A mice. In contrast,
7 activation of ATOH1 alone just one week later in P8 Rosa-A mice is unable to activate POU4F3 expression
8 (Figure 9 – Supplementary Figure 1A) suggesting that components of the hair cell gene regulatory network –
9 even those immediately downstream of *Atoh1* - become refractory to induction by ATOH1 alone in older
0 animals.

1 Our data show that co-expression of GF11 and POU4F3 with ATOH1 in the 8-day old cochlea is
2 sufficient to generate significant numbers of reprogrammed hair cell-like cells by P15, but that ATOH1 alone or
3 ATOH1 + GF11 produce very few new hair cells. It is important to note that the GER is undergoing significant
4 apoptotic remodeling at this time in response to thyroid hormone (Peeters, et al., 2015), as shown by the loss
5 of Sox9 lineage-labeled cells from the cochlea between P8 and P15 (Figure S4A). This remodeling likely leads
6 to a loss of cells capable of being reprogrammed by Rosa-GAP mice, which we suggest leads to an under-
7 estimate of the reprogramming capability of Rosa-GAP mice in these experiments. Nonetheless, despite the
8 presence of significant numbers of newly reprogrammed hair cells in ROSA26-GAP mice, our single-cell RNA-
9 seq analysis of the new hair cell-like cells at P15 reveals no significant differences in their transcriptome
0 compared to the small number of reprogrammed cells generated by Rosa-A and Rosa-GA mice (Figure 6C).
1 These data suggest that although the combination of our three transcription factors can significantly increase
2 the *efficiency* of hair cell reprogramming, they are not able to activate additional components of the hair cell
3 gene regulatory network compared to ATOH1 alone or ATOH1 + GF11 – in other words, the additional
4 reprogramming factors can enhance the quantity of reprogrammed hair cells, but not their “quality”. However,
5 this conclusion should be qualified by several considerations. First, the number of reprogrammed hair cells
6 appearing in our scRNA-seq analysis of Rosa-A and Rosa-GA is very small, and second, since our RNA-seq
7 analysis was performed only one week after activation of the reprogramming factors at P8, additional
8 maturation may likely occur after longer periods. Consistent with this possibility, we note that Myosin VIIa+

1 cells produced by Rosa-GAP mice at P15 do not have organized actin bundles on their apical surface that can
2 be labeled by phalloidin. Significantly, such bundles begin to appear on these GAP-reprogrammed hair cells
3 over the following two weeks, but not in the small number of extra hair cells generated by Rosa-A mice (Figure
4 4 – Supplementary Figure 1B). It is also important to note that our current over-expression model causes
5 continued expression of ATOH1 in our reprogrammed cells, whereas *Atoh1* expression is normally
6 downregulated in hair cells shortly after they begin to differentiate. Such persistent expression may militate
7 against full maturation of the new hair cells generated in our studies, and in previous studies that have used
8 constitutive activation of *Atoh1* as a reprogramming strategy (Chen et al., 2021; Kelly et al., 2012; Lee et al.,
9 2020; Liu et al., 2012; Menendez et al., 2020; Walters et al., 2017; Yamashita et al., 2018).

.0 Supporting cells are essential for the function and survival of inner ear hair cells. During development,
.1 hair cells and supporting cells derive from a common progenitor, and the correct proportion of these two cell
.2 types is regulated by several signaling pathways, most prominently Notch signaling (reviewed by (Basch, et al.,
.3 2016a). Moreover, the generation of reprogrammed hair cells has been shown to generate new supporting
.4 cells in the surrounding tissue through non-cell-autonomous mechanisms, again including Notch signaling
.5 (Wan, et al., 2020; Zhang, et al., 2018; Stone and Cotanche, 1994). In the present study, we have shown that
.6 the production of large numbers of reprogrammed hair cell-like cells in the GER causes the induction of
.7 GLAST+ supporting cells that interleave the new hair cells. Of note, the new hair cells produced in the GER
.8 resemble inner ear hair cells, and our scRNA-seq and antibody characterization shows that the identity of
.9 ectopic supporting cells resembles border cells and inner phalangeal cells, two supporting cell types that
.0 normally surround inner hair cells. Reprogramming in the GER is, therefore, able to generate appropriately
.1 patterned and location-specific mosaics of hair cells and supporting cells similar to those that occur in vivo.

.2 The fact that the new supporting cell-like cells retain their identity despite continuing to express hair cell
.3 reprogramming factors suggests that signaling pathways present in supporting cells can override the action of
.4 the reprogramming factors. Our data also show that some endogenous supporting cells in the organ of Corti –
.5 notably pillar cells and Deiters' cells - remain refractory to the effects of reprogramming factors at both P1 and
.6 P8. We have confirmed the refractory state of these supporting cell types with two different Cre lines, *Sox9-*
.7 *CreER* and *Lfng-CreER* (Figure 7 – Supplementary Figure 1). However, a recent study also expressed

1 ATOH1, GF11, and POU4F3 in different populations of neonatal cochlear supporting cells and reported that
2 some of them are capable of being reprogrammed into hair cells (Chen, et al., 2021). One of the Cre-
3 expressing lines used to activate the reprogramming factors in the study by Chen and colleagues, *Fgfr3-*
4 *iCreER^{T2}*, also expresses functional Cre recombinase in up to 30% of outer hair cells at the experimental time
5 points and ages used in the study (Cox, et al., 2012), so it is likely that many of the labeled outer hair cells
6 were endogenous hair cells present at the start of the experiment. Although the mice generated by Chen et al.
7 apparently targeted the three reprogramming factors to the ROSA locus and employed a chicken beta-actin
8 promoter in the same manner as the Rosa-GAP mice we report here, it is also possible that the two targeted
9 lines express the reprogramming factors at different levels. Although we observe transcriptional changes in
10 supporting cells in response to our three reprogramming combinations (Figure 8), both the hair cells and
11 supporting cells in the organ of Corti remain healthy and viable in all conditions examined (Figure 1-8, S1-S9).
12 In contrast, hair cell loss was observed when ATOH1, GF11, and POU4F3 were activated by either *Fgfr3-*
13 *iCreER^{T2}* or *Lgr5-CreER* mice (Chen, et al., 2021), suggesting that the levels of reprogramming factors used
14 may be important for cochlear cell viability. Hair cell survival appears to be particularly sensitive to ATOH1
15 levels; hair cell loss and hearing deficits are observed in mice with only one functional ATOH1 allele, or with
16 two hypomorphic alleles of ATOH1 (Xie et al., 2017), and so it is likely that future regenerative strategies using
17 ATOH1 will need to calibrate the level and duration of this important transcription factor with great precision.

18 Several lines of evidence suggest that Notch signaling may be responsible for overriding the
19 reprogramming ability of our transcription factor combinations. First, most organ of Corti supporting cells in
20 neonatal mice rapidly and readily trans-differentiate into hair cells when Notch signaling is blocked (Jiang, et
21 al., 2014; Korrapati, et al., 2013; Mizutari, et al., 2013). Second, blocking Notch signaling with gamma-
22 secretase inhibitors can cause ectopic supporting cells in the GER created by ATOH1 reprogramming to
23 transdifferentiate to hair cells (Kelly, et al., 2012). Third, our scRNA-seq data suggests that elements of the
24 Notch signaling pathway are reconstituted in the ectopic supporting cells generated in our mice (Figure 7), and
25 in endogenous supporting cells that receive reprogramming factors from P8-P15 (Figure 8). This latter result is
26 particularly notable, as supporting cells normally transcriptionally and epigenetically down-regulate the Notch
27 pathway in the first postnatal week and become refractory to Notch inhibition (Tao, et al., 2021; Maass, et al.,
28 2016; Maass, et al., 2015). Together, our data suggest that transcription factor reprogramming may

1 reconstitute some of the transcriptional and epigenetic regulation that normally exists between developing hair
2 cells and supporting cells, and it will be of interest in the future to understand how fully these regulatory circuits
3 can be established by different combinations of transcription factors. In addition to the effects of Notch
4 signaling, our multi-omic analysis of cochlear tissue at P1 and P8 shows clearly that the chromatin of hair cell
5 loci becomes less accessible in supporting cells and GER cells during the first postnatal week (Figure 9). This
6 decrease in accessibility affects hair cell loci in general, but significantly is also seen in key hair cell
7 transcription factors downstream of *Atoh1*, including *Gfi1* and *Pou4f3* (Figure 9 – Supplementary Figure 1A).
8 By using a single cell multi-omic analysis, we were able to demonstrate these epigenetic changes occurring in
9 all supporting cell and GER cell populations during the first postnatal week. We suggest that this decrease in
0 accessibility is a second element contributing to the need for multiple transcription factors to reprogram more
1 mature cochlear tissue.

2 In conclusion, our work shows that while overexpression of multiple hair cell transcription factors in the
3 cochlea clearly promotes more efficient reprogramming in older animals, significant challenges to producing
4 viable, functional hair cells still remain. Future work will be necessary to determine whether more functional
5 hair cells can be generated with extra hair cell transcription factors, by epigenetic modulation of hair cell loci in
6 supporting cells, or by actively targeting the down-regulation of supporting cell genes during reprogramming.
7 Finally, we emphasize that our present work focuses exclusively on the intact organ of Corti. We currently do
8 not know what effect the acute and long-term pathological consequences of hair cell loss in the cochlea will
9 have on the efficiency and fidelity of hair cell reprogramming, and addressing this question will be critical to
0 promoting functional hair cell regeneration in the mammalian cochlea.

1

1 MATERIALS AND METHODS

2 Targeting of the ROSA locus:

3 The three conditional lines for transcription factor overexpression (Rosa-A, GA, GAP) were constructed by
4 modifying the *Ai3* targeting construct (Addgene #22797; (Madisen, et al., 2010). The EGFP insert in *Ai3* was
5 removed by FseI digestion and replaced with coding regions for the following: ROSA-A: *Atoh1* fused to EGFP
6 (Rose, et al., 2009); ROSA-GA: *Gfi1* and *Atoh1-EGFP* separated by a GSG-P2A sequence; ROSA-GAP: *Gfi1*,
7 *Atoh1-EGFP*, and *Pou4f3* separated by GSG-P2A sequences. The targeting constructs were digested with
8 PacI and AscI to separate the construct from the homology arms and cloned into a p15a-based targeting
9 vector containing homology arms for the ROSA26 locus (5': 1057bp; 3': 1231bp). Linearized targeting
0 constructs (2µg) were electroporated into AB2.2 ES cells with 20µg of a pX330 plasmid (Addgene # 42230)
1 expressing Cas9 and a sgRNA sequence to target the ROSA26 locus just inside the 5' homology arm:
2 ACTGGAGTTGCAGATCACGA GGG (PAM sequence is shown in italics). 48 Neomycin-resistant clones were
3 picked, verified for correct targeting of the ROSA26 locus, expanded, and injected into 129 blastocysts to
4 create chimeras, which were then bred to C57Bl6 mice to establish germline founders.

5 Experimental animals:

6 All mouse experiments were performed at Baylor College of Medicine and approved by the Institutional Animal
7 Care and Use Committee (IACUC). In addition to the *Rosa26*-targeted mice described above, we also used
8 several lines available from the Jackson Laboratory: *Sox9-CreER^{T2}* mice (*Tg(Sox9-creERT2)1Msan/J*;
9 stock# 018829; RRID:IMSR_JAX:018829), *Lfng-CreER* mice (*Tg(Lfng-cre/ERT2)1Mmsa/J*; stock# 035554;
10 RRID:IMSR_JAX:035554), *Ai3* EGFP Cre reporter mice (*Cg-Gt(ROSA)26Sor^{tm3(CAG-EYFP)Hze/J}*; stock #007903;
11 RRID:IMSR_JAX:007903) and *Ai9* tdTomato Cre reporter mice (*Cg-Gt(ROSA)26Sor^{tm9(CAG-tdTomato)Hze/J}*; stock#
12 007909; RRID:IMSR_JAX:007909). *Ai3* and *Ai9* mice are described in (Madisen, et al., 2010). For single-cell
13 RNA sequencing work, we incorporated the *Ai9* reporter allele into our three types of crosses to yield mice of
14 the genotypes *Sox9-CreER^{T2};*Rosa26*^{Atoh1/Gfi1-Atoh1/Gfi1-Atoh1-Pou4f3}*, *Rosa26^{tdtomato}*. Experimental animal genotypes
15 for all other work were *Sox9-CreER^{T2};*Rosa26*^{Atoh1/Gfi1-Atoh1/Gfi1-Atoh1-Pou4f3}*

16

1 **Mouse genotyping:**

2 The following primer pairs were used for genotyping:

3 *Sox9-CreER^{T2}* mice and *Lfng-CreER* mice: Forward primer – (GCC TGC ATT ACC GGT CGA TGC AAC GA),
4 reverse primer – (GTG GCA GAT GGC GCG GCA ACA CCA TT) yielding a band of 700bp.

5 *Ai3* EGFP and *Ai9* tdTomato Cre reporter mice: Wild type forward primer (AAG GGA GCT GCA GTG GAG
6 TA), wild type reverse primer – (CCG AAA ATC TGT GGG AAG TC), mutant forward primer – (ACA TGG TCC
7 TGC TGG AGT TC), mutant reverse primer (GGC ATT AAA GCA GCG TAT CC) yielding a wild type band of
8 297bp and a mutant band of 212bp (<https://www.jax.org/Protocol?stockNumber=007903&protocolID=28710>).

9 EGFP could also be detected with forward primer – (CGA AGG CTA CGT CCA GGA GCG CAC), reverse
0 primer – (GCA CGG GGC CGT CGC CGA TGG GGG TGT) yielding a band of 300bp.

1 *ROSA* modified reprogramming mouse alleles: The wild type *ROSA* allele was detected using the wild type
2 primers for *Ai3* and *Ai9* listed above, yielding a band of 297bp. The *ROSA-A* allele was specifically detected
3 with forward primer – (AAA TGA CCA CCA TCA CCT TCG CAC C) and reverse primer – (ACG CTG AAC TTG
4 TGG CCG TTT ACG TC), yielding a band of 483bp. The *ROSA-GA* allele was specifically detected with
5 forward primer – (ACA TCT GCT CAT TCA CTC GGA CAC C) and reverse primer – (TTT ACC TCA GCC
6 CAC TCT TCT GCA TG), yielding a band of 384bp. The *ROSA-GAP* allele was specifically detected with
7 forward primer – (CTA TTT CGC CAT CCA GCC ACG TCC TTC) and reverse primer – (GAC AAC GGG CCA
8 CAA CTC CTC ATA AAG), yielding a band of 375bp.

9 **Tamoxifen treatment:**

10 Tamoxifen (Sigma Aldrich) was dissolved in peanut oil at a concentration of 20mg/ml. This solution was
11 volume optimized and injected subcutaneously at a dosage of 0.2mg/g body weight into P1 and P8 animals.
12 Experimental and control littermates were genotyped and segregated after harvest.

13 **Western blotting:**

14 Cells were lysed in lysis buffer (50 mM Tris-HCl, pH 7.5, 150 mM NaCl, 0.5% Triton X-100, 5% glycerol, 1%
15 SDS, 1x protease inhibitor cocktail). Protein concentrations were determined using a BCA assay kit (Bio-Rad).

1 Ten µg of protein lysate was boiled with 6X SDS sample buffer (0.5 M Tris-HCl pH 6.8, 28% glycerol, 9% SDS,
2 5% 2-mercaptoethanol, 0.01% bromophenol blue) and electrophoresed on a 4-15% Criterion™ Tris-HCl gel
3 (Bio-Rad) and transferred onto a PVDF membrane. Membranes were blocked for 1 h at room temperature or
4 overnight at 4°C using blocking buffer (5% milk in TBST). Following blocking, membranes were incubated with
5 appropriate dilutions of primary antibody (GFP 1:500 (Santa Cruz), ATOH1 1:1000 (Proteintech), GF11 1:1000
6 (Abcam), POU4F3 1:500 (Santa Cruz)) in blocking buffer for overnight 4°C on a rocker. Next, membranes were
7 washed 3 times in TBST, 5 min each at room temperature. After this, membranes were incubated with the
8 recommended dilution of conjugated secondary antibody in blocking buffer at room temperature for 1 hour.
9 Membranes were washed 3 times in TBST, 5 min each. The signals were developed using Immobilon Western
10 Chemiluminescent HRP Substrate (Millipore) and detected using ImageQuant LAS 4000 (GE Healthcare)
11 according to the manufacturer's instructions.

12 **Fixation, dissection, and cryosectioning:**

13 Temporal bones from P8 and P15 mice were harvested and fixed in 4% paraformaldehyde for 2 hours at room
14 temperature on a shaker. Fixed temporal bones were stored in 1X PBS at 4°C and microdissected with fine
15 forceps to peel out the cochlear epithelium. In some cases, P15 temporal bones were decalcified in 0.3-0.5M
16 EDTA (pH 8.0) for 3-4 hours at room temperature. For cryosectioning, samples were immersed in a 15%
17 sucrose (Fisher Bioreagents #141913) solution at 4°C overnight. The temporal bones were then incubated for
18 two hours in a sucrose-gelatin solution (7.5% gelatin (Sigma SLBX 2973) /15% sucrose and 0.0025mg of
19 sodium azide in 1X PBS, dissolved at 65°C and stored at 37°C), followed by embedding and sectioning to give
20 12-14µm serial sections on a Leica CM 1850 cryostat.

21 **Immunohistochemistry:**

22 Whole cochlear epithelia were permeabilized with 0.5% Triton-X in 1X PBS at room temperature for 20
23 minutes. Sections were subject to gelatin removal by incubating in 1X PBS at 37°C for 10 minutes followed by
24 washing. Note - The mouse Myosin VIIA and Rat SOX2 antibodies require a specific antigen retrieval step at
25 this point. The slides/tissues were incubated in the antigen retrieval solution (10mM sodium citrate solution
26 made by dissolving sodium citrate salt or citric acid powder in distilled water. The pH of this solution is adjusted
27 to 6.0 using conc.HCl or NaOH respectively. 0.05% Tween 20 is added and dissolved to get a clear solution)

1 for 15 minutes at 80°C. The samples were cooled to room temperature without replacing the solution and
 2 washed three times. Sections were permeabilized with 0.3% Triton-X in 1X PBS at room temperature for 5
 3 minutes. Post permeabilization, tissues (whole cochlear epithelium and sections) were washed three times with
 4 1X PBS for 10 minutes each. Tissues were blocked with 10% goat serum for 1 hour at room temperature.
 5 Primary antibody combinations were diluted in 5% goat serum with 0.2% Triton-X and incubated overnight at
 6 4°C. Note- For the rabbit anti-PROX1, blocking and antibody dilutions were in 10% and 1% donkey serum
 7 along with Triton X-100 respectively. For the anti-CTBP2 staining, primary antibody incubation was at 37°C
 8 overnight in a humidified chamber. After three washes with 1X PBS, tissues were incubated with fluorescently
 9 labeled secondary antibodies diluted in 5% goat serum with 0.2% Triton-X or 1X PBST and incubated for 2
 0 hours at room temperature. Tissues were counterstained with DAPI (1:5000), washed, and dried. Tissues were
 1 mounted using the Fluormount (Southern Biotech) mounting medium, sealed with glass coverslips, and dried
 2 before imaging.

3 **Antibodies:**

Antigen	Host	Source	RRID	Dilution
Myosin VIIa	Rabbit polyclonal	Proteus Biosciences 25-6790	AB_10015251	1:300
Myosin VIIa	Mouse polyclonal	DSHB 138-1	AB_2282417	1:200

1

2 **Microscopy and image processing:**

3 Immunostained samples were viewed on an LSM 780 confocal microscope in the Baylor Optical Imaging &
4 Vital Microscopy Core at 20X and with emulsion oil applied to a 40X objective lens. Exposure levels were
5 maintained between slides that were part of the same experimental batch. Maximum intensity projections
6 obtained after processing z-stacks were processed using Adobe Photoshop CS6. Processing steps include
7 normalization of intensity levels and derivation of 200µm lengths of the tissue measured using the scale bar
8 option on the Zen Blue 3.1 software.

9 **Cell number quantification:**

0 All the images that were used for cell counting were analyzed on Zen Blue 3.1. Counting was done by using
1 the event and marker options that sum the number of objects clicked upon. Inner hair cells, outer hair cells,
2 and GER hair cells from 3 images were counted per genotype – WT, Rosa-A, Rosa-GA, and Rosa-GAP. Bar
3 graphs were plotted employing the Graphpad Prism 5.0 software after performing an unpaired t-test comparing
4 the control and each induced condition, to determine significance. For all experiments, three biological
5 replicates (i.e. parallel measurements of biologically distinct samples) were used.

6 **Scanning electron microscopy:**

7 Fixing solution (all reagents from Electron Microscopy Solutions) was prepared by mixing 8% glutaraldehyde
8 (2% final concentration), 0.6M Cacodylate buffer (pH 7.2-7.4; 0.15M final concentration) and distilled water.
9 The temporal bones from P8 and P15 experimental animals were removed, and the apex region of each
0 sample was punctured. The temporal bones were incubated in the SEM fixing solution for 2 hours at room

1 temperature. Post incubation, the temporal bones were rinsed and stored in 0.6M cacodylate buffer at 4°C.
2 Samples were micro-dissection to expose the organ of Corti and processed with the OTOTO method for
3 scanning electron microscopy. Tissues were then dehydrated in graded ethanol solutions, critical point dried,
4 and mounted on a stub using silver paste. Images were taken with a TESCAN Rise scanning electron
5 microscope.

6 **FM 1-43 dye uptake assay:**

7 FM 1-43 dye solution was prepared by dissolving a 10µg/µl stock of FM 1-43 (Thermo Fisher, Cat no. T35356)
8 dye in EBSS/HBSS to a final concentration of 2µg/ml in 0.5ml. One cochlea at a time was dissected from live
9 P8 experimental mice and placed on a glass slide. The tissue was incubated in 20 µl of the dye solution for 10-
10 12 seconds and immediately washed with 1X PBS. The orientation of the tissue was checked followed by the
11 addition of mounting medium. The mounted tissue was sealed with a glass coverslip and imaged under the
12 488 (green) channel of a Zeiss fluorescence microscope. The light intensity and brightness were normalized
13 for images captured from different samples using the endogenous hair cells as a reference.

14 **Cell Proliferation assay and EdU staining:**

15 An EdU injection solution of 5mg/ml concentration was prepared by dissolving EdU powder (Thermo Fisher
16 Scientific, #A10044) in 1X PBS pH 7.4 (Thermo Fisher Scientific, #10010023). Pups were weighed and
17 injected with this solution at a dose of 50mg/kg body weight, subcutaneously. Injections were given twice every
18 alternate day (9 am and 5 pm). Mice at P8 and P15 were collected, fixed, and cryosectioned following the
19 procedures described above for IHC. EdU visualization was done using the Click-iT™ EdU Cell Proliferation Kit
20 for Imaging, Alexa Fluor™ 488 dye (Thermo Fisher Scientific, #C10337) following the manufacturer's
21 instruction accompanying the kit. Co-immunostaining with primary antibody for Myosin VIIA was performed as
22 described previously in this section.

23 **Single-cell dissociation of cochlear cells and FACS purification:**

24 Whole ears from P8 mice were harvested and transferred to a dish of ice-cold CMF PBS. The organ of Corti
25 was dissected from controls and experimental samples into separate microcentrifuge tubes with 0.3ml ice-cold
26 CMF PBS placed on ice. For P15 animals, whole temporal bones were cleaned and punctured at the apex,

1 then placed into tubes with 0.3ml ice-cold CMF PBS. In both cases, tissue was washed twice with 0.3ml ice-
2 cold CMF PBS and incubated in 0.3ml papain solution (20U/ml, 1mM L-Cysteine and 0.5mM EDTA;
3 Worthington Biochemical Corporation) at 37°C for 40 minutes. The papain solution was removed carefully, and
4 the tissue was washed twice with 0.3ml ice-cold CMF PBS containing 2-5% FBS. The tissue was triturated for
5 3-4 minutes by placing tubes on ice with minimal frothing, then filtered (40-micron then 35-micron filter caps –
6 Pluriselect) into a 5ml round bottom polystyrene tube to remove clumps and bone fragments before sorting.
7 Dissociated cells were sorted on an Ariall FACS sorter at the BCM Flow Cytometry core. The presort
8 conditions specified for the nozzle were 20psi pressure and 100µm size respectively. TdTomato positive sorted
9 cells were collected in DMEM with 5% FBS solution for cDNA library preparation and single-cell RNA
.0 sequencing.

.1 **cDNA library preparation:**

.2 Purified cells were counted to estimate concentration and loaded onto a 10X genomics Chromium controller to
.3 prepare single-cell 3' RNA seq libraries using the Chromium single cell 3' reagent kit v3 (10x Genomics). In
.4 brief, single cells were partitioned into GEMS (Gel Beads-In-Emulsions) that contain a gel bead with primers
.5 that include a Illumina Truseq Read 1 primer, a 16 nucleotide (nt) 10x barcode, a 12 nt unique molecular
.6 identifier and a 30 nt poly(dT) sequence and all the necessary components to perform reverse transcription.
.7 Almost simultaneously, the gel bead is dissolved and the partitioned cell is lysed releasing all the cellular RNA.
.8 Incubation of these components inside the GEM results in synthesis of full-length barcoded cDNA from the
.9 mRNA. Subsequently, the GEMS are lysed and cDNA from all the single-cells are pooled. Following cleanup
.0 using Dynabeads MyOne Silane Beads (Thermo Fisher, 370020), cDNA was amplified by PCR and
.1 fragmented to optimal size before end-repair, A-tailing, and adaptor ligation to prepare the paired end illumina
.2 libraries followed by a final PCR to amplify the library.

.3 **Single-cell RNA sequencing and analysis:**

.4 Sample QC was conducted using the NanoDrop spectrophotometer and Agilent Bioanalyzer 2100 (High
.5 Sensitivity DNA Chip, p/n 5067-4626). To quantitate the adapter-ligated library and confirm successful P5 and
.6 P7 adapter incorporations, the Applied Biosystems ViiA7 Real-Time PCR System and a KAPA
.7 Illumina/Universal Library Quantification Kit (p/n KK4824) were used. All samples were pooled at equimolar

1 amounts and re-quantitated by qPCR and re-assessed on the Bioanalyzer. Using the concentration from the
2 ViiA7 TM qPCR machine above, 300pM of the pooled library was loaded onto a NovaSeq S1 flowcell (Illumina
3 p/n 20012865), using the Standard Workflow loading conditions designated by the manufacturer and amplified
4 by exclusion amplification (ExAMP) for patterned flowcells using the Illumina NovaSeq 6000 sequencing
5 instrument. PhiX Control v3 adapter-ligated library (Illumina p/n FC110-3001) was spiked-in at 1% by weight to
6 ensure balanced diversity and to monitor clustering and sequencing performance. A paired-end run, using 28
7 cycles for Read 1, 8 cycles for Index 1 Read and 91 cycles for Read 2 was set to achieve a minimum of
8 approximately 300M reads per sample. FastQ file generation and QC assessment were achieved using the
9 10X Cell Ranger software for 10X Chromium Platforms. Sequencing data has been uploaded to the GEO
.0 database (<https://www.ncbi.nlm.nih.gov/geo>), accession number GSE182202.

.1 The unique molecular identifier (UMI) count matrices were generated by aligning the raw reads to the mm10
.2 (GRCm38) genome along with the annotation gtf file (GRCm38release-93) (from Ensembl) using the count
.3 function of the 10x genomics Cell Ranger pipeline. Alignment, filtering, barcode, and UMI counting were also
.4 performed with Cell Ranger. The R package Seurat (v3.2) was used to process the count matrices. First, the
.5 count matrices were transformed into Seurat objects, and cells expressing less than 200 genes and genes
.6 expressed in less than 5 cells were filtered and excluded from the analysis. Another round of filtration was
.7 performed based on the distribution of the nUMI, nFeature, and percentage of mitochondrial genes expressed
.8 per cell in each dataset. Cells expressing less than 750 genes and more than 5000 genes as well as cells with
.9 greater than 30% mitochondrial genes were excluded from further analysis. The number of cells analyzed per
.0 genotype at each timepoint is given in the table below.

.1

	Wildtype	Rosa26-A	Rosa26-GA	Rosa26-GAP
Age				
P8	5079	8179	3097	8957
P15	4614	4015	840	3758

.2

1 Each dataset was normalized using the logNormalize function, which divided the gene counts for each cell by
2 its total counts; followed by the identification of the top 2000 variable genes using the FindVariableFeatures
3 function.

4 To identify clusters that differed between the wildtype and the transcription factor-induced datasets, an
5 integrated analysis of the cells of all the genotypes was performed. First, we identified the integration anchors
6 for the 4 datasets and used them to integrate the datasets using the IntegrateData function. Next, the
7 integrated dataset was scaled by multiplying the normalized values by a factor of 10000, followed by
8 dimensionality reduction by principal component analysis (PCA). Top 40 principal components were chosen as
9 significant based on a Jackstraw plot and used to construct a shared nearest neighbor (SNN) graph using the
10 FindNeighbors function. Cells were then clustered at various resolutions ranging from 0.2 to 1.0 using the
11 Leiden algorithm in the FindClusters function of Seurat. The conserved gene markers for each cluster across
12 the different genotypes were identified with the FindConservedMarkers function and unique gene markers for a
13 given cluster were identified using the FindMarkers or for all clusters with FindAllMarkers function. The
14 FindClusters and FindMarkers functions were iterated at the different resolutions until clusters with biological
15 relevance and expected cell types were observed at a resolution of 0.8.

16 Each cell-type-specific cluster was identified by ranking differentially expressed genes based on the p-value of
17 expression, average log fold change of expression, and the difference in pct1 vs pct2. A search for cell type-
18 specific expression of the top-ranked genes yielded results unique to cell types and was thus labeled. Gene
19 ontology analysis involved the selection of all significantly expressed genes in the hair cell clusters of the P8
20 and P15 datasets with a cut-off p-value of less than $1.00E^{-03}$. The analysis was done on DAVID
21 (<https://david.ncifcrf.gov/tools.jsp>) with this gene list as input. Resultant GO terms and associated p-values (cut
22 off $1.00E^{-02}$) are represented in the figure. Volcano plots for all differentially expressed genes were plotted
23 using GraphPad Prism 5.0. All cutoffs assigned are marked with dotted lines on the plots.

24 **Multomic (combined scRNA- and ATAC-seq) sample processing**

25 For Single Cell Multiome ATAC + Gene Expression (10x Genomics) experiments, wildtype mice in a mixed
26 background of CD1 and FVB/NJ, and C57BL/6 were used. Cochlear tissue was dissected from P1 and P8
27 mice and enzymatically dissociated with a cocktail of 400µl of 0.25% Trypsin, 50µl of 1 mg/ml Dispase, and

1 50µl of 1 mg/ml collagenase for 20 minutes at 37°C. After incubation, the digested tissue was titrated 100
2 times using a small-bore 200µl pipette and centrifuged at 500x g for 5 minutes at 4°C. After centrifugation, the
3 sample was processed according to the 10x Genomics protocol “Nuclei Isolation from Complex Tissues for
4 Single Cell Multiome ATAC + Gene Expression Sequencing” (CG000375, Rev B). Briefly, the supernatant was
5 decanted, and the cell pellet was resuspended in 1ml of NP-40 Lysis Buffer and incubated for 5 min on ice.
6 Nuclei were filtered through a 40 micron cell strainer, and centrifuged at 500x g for 5 minutes at 4°C. The
7 supernatant was decanted, and nuclei were resuspended in 1ml of PBS + 2% BSA and incubated for 5 min at
8 4°C. Nuclei were centrifuged at 500x g for 5 minutes at 4°C, resuspended in 100ul of 0.1x Lysis Buffer, and
9 mixed with a pipet. Nuclei were incubated for 2 minutes on ice, followed by the addition of 1ml Wash Buffer,
0 mixed and centrifuged at 500x g for 5 minutes at 4°C, and resuspended in the appropriate volume of Diluted
1 Nuclei Buffer for input into the Single Cell Multiome ATAC + Gene Expression protocol (10x Genomics). For
2 the P1 cochlea, 6,065 nuclei were loaded. For the P8 cochlea, 9,645 nuclei were loaded.

3 **Multomic data processing**

4 Raw sequencing data from both RNA and ATAC libraries in fastq format were used as input into cellranger-arc
5 count (10x Genomics, v2.0.0) for simultaneous alignment against the mouse mm10 genome. The cellranger-
6 arc output files ‘filtered_feature_bc_matrix.h5’ and ‘atac_fragments.tsv.gz’ were used as input into Seurat
7 v4.1.0 for standard quality control pre-processing, resulting in 4,882 nuclei post-filtering for the P1 dataset, and
8 7,049 nuclei post-filtering for the P8 dataset. ATAC peaks were called using macs2 v2.1.2. Multiome datasets
9 were clustered based on RNA, ATAC, and weighted-nearest neighbor (Hao et al, 2021) to generate UMAPs.
0 This resulted in 20 clusters for the P1 dataset, and 19 clusters for the P8 dataset. Clusters were assigned cell
1 types based on known cell markers. Cell barcodes from clusters of interest (P1 GER, P8 GER, P1 IPh/BC, P8
2 IPh, and P8 BC) were used to extract ATAC reads belonging to each respective cell type and generate a
3 pseudobulk ATAC dataset. Peaks were called on the pseudobulk ATAC datasets and common peaks were
4 used as input into DESeq2 v1.34.0 to scale the signal between P1 and P8 datasets. Representative signal
5 tracks were visualized in IGV v2.4.14. ATAC peaks were filtered by hair cell enhancers previously identified
6 (Tao et al., 2021), and intersected to find common, P1-specific, and P8-specific regions. Heatmaps were
7 generated using deepTools v3.2.0 computeMatrix and plotHeatmap.

1 MATERIALS AVAILABILITY STATEMENT

2 The three ROSA-targeted mouse lines (ROSA-A, ROSA-GA and ROSA-GAP) are available from the
3 corresponding author upon request.

4

5 ACKNOWLEDGEMENTS

6 We would like to acknowledge members of the Groves lab for their help, particularly Melissa McGovern for
7 cryosectioning and dissection advice and Alyssa Crowder for technical assistance. We thank Gabriella Perez
8 from the Jankowsky lab for help with the CTBP2 imaging. We thank Jing Zheng from Northwestern University
9 for providing the Prestin antibody. We acknowledge Teng-Wei Huang for advice with immunostaining
.0 protocols.

.2 FUNDING

.3 The project was supported by the following grants: RO1 DC014832 (A.K.G.; subcontract to Y.R.), R21
.4 OD025327 (R.S.R.), DC015829 (N.S.), and a Hearing Restoration Project Consortium award from the Hearing
.5 Health Foundation (A.K.G. and N.S.). The project was also supported by the following cores at Baylor College
.6 of Medicine: the Optical Imaging & Vital Microscopy Core with assistance from Jason Kirk; the Cytometry and
.7 Cell Sorting Core with funding from the CPRIT Core Facility Support Award (CPRIT-RP180672), and the NIH
.8 (P30 CA125123 and S10 RR024574) and assistance from Joel M. Sederstrom, Bethany Tiner and Amanda
.9 White; the Single Cell Genomics Core, with instrument grants from the NIH (S10OD018033, S10OD023469,
.0 S10OD025240) and P30EY002520) and assistance from Rui Chen and Yumei Li; the Genomic and RNA
.1 Profiling Core with assistance from Daniel Kraushaar; the Genetically Engineered Rodent Models core with
.2 assistance from Lan Liao and Isabel Lorenzo. The scanning electron microscopy (SEM) work was supported
.3 by the R. Jamison and Betty Williams Professorship. The SEM unit receives financial support from the
.4 University of Michigan College of Engineering and NSF grant #DMR-1625671, and technical support from the
.5 Michigan Center for Materials Characterization.

1 **FIGURE LEGENDS**

2 **Figure 1: Non-sensory cells of the neonatal mouse cochlea can be efficiently reprogrammed to a hair** 3 **cell fate with combinations of Atoh1, Gfi1 and Pou4f3 transcription factors**

4 (A) Schematic representation of the strategy to target the *Rosa26* locus to generate three conditional mouse
5 lines for transcription factor overexpression. A modified Ai3 vector (Madisen et al., 2010) was used to target
6 different transcription factor combinations to the *ROSA26* locus. ES cell targeting was enhanced using
7 CRISPR-mediated cleavage with a sgRNA sequence targeting the *ROSA26* locus between the targeting
8 homology arms (HA1 and 2). The transcription factor coding sequences were separated by GSG-T2A self-
9 cleaving peptide sequences to generate multiple proteins from a single primary transcript.

0 (B) Mating schemes to express different transcription factor combinations in the cochlea. The *Sox9-CreER*
1 mouse was bred to the three *Rosa26* overexpression lines and reporters to generate experimental animals of
2 the following genotypes: *Rosa26-A* (*Sox9-CreER*; *Rosa*^{*Atoh1**GFP*}), *Rosa26-GA* (*Sox9-CreER*; *Rosa*^{*Gfi1-Atoh1**GFP*}),
3 *Rosa26-GAP* (*Sox9-CreER*; *Rosa*^{*Gfi1-Atoh1**GFP-Pou4f3*}), *Rosa26-EGFP* (*Sox9-CreER*; *Rosa26*^{*EGFP*}), and *Rosa26-*
4 *tdtomato* (*Sox9-CreER*; *Rosa26*^{*tdtomato*}). Animals received tamoxifen (25mg/kg body weight) at P1 and were
5 sacrificed at P8.

6 (C) GFP reporter expression obtained from mating *Sox9-CreER* mice with *Rosa26*^{*EGFP*} mice. Fluorescence is
7 seen in all GER cells in whole mounts and 16 μ m sections. Images show GFP (green) and a DAPI nuclear
8 stain (magenta). Scale bar: 50 μ m.

9 (D) Large numbers of reprogrammed hair cells (white arrows) are seen in P8 cochleae extending from the
10 organ of Corti to the interdental cell region in *ROSA-A*, *ROSA-GA*, and *ROSA-GAP* mice, revealed by
11 immunostaining for Myosin VIIA (red) and Phalloidin (green).

12 (E) Quantification of hair cells in the P8 reprogrammed cochleae. The number of Myosin VIIA+ cells per 200
13 μ m length of the cochlea was measured (IHC – Inner hair cells, OHC – Outer hair cells). Compared to controls,
14 significant numbers of reprogrammed cells (300-320 per 200 μ m) were seen in *Rosa26-A*, *Rosa26-GA* and
15 *Rosa26-GAP* genotypes (n=3 per genotype). An unpaired t-test was performed to compare hair cell numbers

1 between genotypes. The significant differences are represented. ****p < 0.00001. Data are presented as mean
2 ± SEM.

3 **Figure 2: Day 8 reprogrammed hair cells are inner hair cell-like, innervated, form ribbon synapses,**
4 **possess stereociliary bundles, and show evidence of mechanotransduction activity**

5 (A) Control and reprogrammed cochleae were immunostained for an inner hair cell-specific marker, VGLUT3,
6 an outer hair cell-specific marker, PRESTIN, a GER specific marker, CD326/EpCAM, a neuronal marker TuJ1,
7 a ribbon synapse-specific marker, and a hair cell marker, Myosin VIIA. The reprogrammed hair cell region is
8 indicated (white line; eHC – ectopic hair cells). Arrows indicate individual ribbon synapse structures observed
9 in the cell bodies of hair cells. Scale bar: 50 µm.

0 (B) Scanning electron micrographs (SEM) of the control and reprogrammed cochleae (500X; scale bar- 50
1 µm). OHC: Outer hair cell region, IHC: Inner hair cell region, GER: greater epithelia ridge region. Arrows
2 indicate individual reprogrammed hair cells in the GER. SEM mages at 10,000X show the arrangement of
3 stereocilia in control and reprogrammed hair cells. Arrows indicate variations in the length of individual
4 stereocilia which are similar between control and reprogrammed hair cells. The presence of
5 mechanotransduction activity in the induced hair cells was tested by uptake of FM1-43 dye after 10 seconds of
6 exposure. Reprogrammed hair cells in the GER take up the dye to a lesser extent than endogenous hair cells
7 (arrows), but more than controls, indicating some mechanotransduction channel activity.

8 **Figure 3: Single-cell transcriptomic analysis of control and reprogrammed P8 GER cells confirm the**
9 **presence of a large number of reprogrammed cells that possess hair cell-like gene signatures**

0 (A) Mice carrying a *Sox9-CreER* allele, a *ROSA26^{tdTomato}* reporter allele, and a modified *ROSA26* allele
1 containing reprogramming factors received tamoxifen at day 1 and tdTomato+ cells were purified by FACS
2 sorting one week later. A representative whole-mount image of a day 8 cochlea shows reprogrammed hair
3 cells and the tdTomato reporter (scale bar: 50 µm). A representative FACS plot of dissociated cochlear cells is
4 shown. tdTomato+ cells were collected and analyzed by scRNA-seq.

1 (B) UMAP plot for cells integrated and analyzed from all four genotypes (Control, Rosa26-A, Rosa26-GA, and
2 Rosa26-GAP) purified in (A). Each identified cluster has been labeled and the anatomical location of each
3 cluster is shown color-coded in panel (D).

4 (C) Genotype-wise UMAP plots highlighting the contribution of cells from each genotype in every identified
5 cluster. The GER cluster (particularly LGER) in the control is prominent and the hair cell cluster is present only
6 in the reprogrammed cochlear genotypes as the Sox9-CreER line does not label endogenous hair cells. IP/IB –
7 Inner phalangeal/border, PC/DC – Pillar/Deiters' cells, HC – Hair cells, LGER – Lateral Greater epithelial ridge

8 (D) Schematic of an organ of Corti cross-section at P8. Unique cell types identified in the scRNA-seq clustering
9 have been color-coded and correspond to the cluster colors in (B) and (C).

0 (E) Gene ontology analysis of the top differentially expressed genes in the reprogrammed hair cell-like cells
1 from all three conditions (with respect to their expression in other cell clusters). A list of ~500 significantly
2 expressed genes ($p < 1.00E^{-25}$) was analyzed and GO terms (Biological process; $-\log_{10}(p\text{-value}) > 1$) are
3 shown.

4 **Figure 4: *Gfi1*, *Atoh1*, *Pou4f3*, but not *Atoh1* or *Gfi1* + *Atoh1*, can reprogram 8-day old GER cells into**
5 **hair cell-like cells**

6 (A) Mating scheme for the targeting of transcription factors to the greater epithelial ridge and all supporting
7 cells. The *Sox9-CreER* mouse is bred to the three Rosa26 overexpression lines in a similar manner to Figure
8 1A. Animals received tamoxifen (25mg/kg body weight) at P8 and were sacrificed at P15.

9 (B) GFP reporter expression in some lateral GER cells and all supporting cells detected by immunostaining in
0 the organ of Corti of the *Sox9-CreER*; *Rosa26-EGFP* cochlea. Images show detection of GFP (green) and
1 nuclear stain, DAPI (magenta). Scale bar: 50 μm .

2 (C) Quantification of hair cells in the P15 reprogrammed cochleae. The number of Myosin VIIA+ cells per 200
3 μm length of the organs of Corti from control, Rosa26-A, Rosa26-GA and Rosa26-GAP genotypes (n=3 per
4 genotype) are represented. ROSA-GAP mice show approximately 50-60 ectopic hair cells, whereas ROSA-A
5 and ROSA-GA show less than 5 ectopic cells per 200 μm . An unpaired t-test was performed to compare hair

1 cell numbers between genotypes. Significant differences are represented. $^{***}p < 0.001$. Data are presented as
2 mean \pm SEM.

3 (D) Rosa26-GAP mice can reprogram GER cells to hair cell-like cells. Immunostaining for Myosin VIIA (red)
4 and Phalloidin (green) in the P15 cochleae (whole-mount organ of Corti - 200 μ m length) of control, Rosa26-A,
5 Rosa26-GA, and Rosa26-GAP mice. Arrows point to the GER region in the Rosa26-GAP cochlea, where many
6 reprogrammed hair cells are observed.

7 **Figure 5: Postnatal (P15) Rosa26-GAP reprogrammed hair cells are innervated and form ribbon**
8 **synapses, but possess immature stereociliary bundles**

9 (A) Control and reprogrammed cochleae immunostained for the inner hair cell-specific marker, VGLUT3, outer
10 hair cell-specific marker, PRESTIN, neuronal marker TuJ1, ribbon synapse-specific marker CTBP2 and hair
11 cell marker, Myosin VIIA. Arrows point to reprogrammed hair cells that are positive for Myosin VIIA in the
12 Rosa26-GAP condition, innervation of the reprogrammed hair cells, and individual ribbon synapse structures
13 observed in the cell bodies of endogenous and reprogrammed hair cells (Rosa26-GAP). Images show
14 detection of described markers on a 16 μ m section of the organ of Corti (control and reprogrammed). Scale
15 bar: 50 μ m.

16 (B) Scanning electron micrographs of reprogrammed hair cells from all three genotypes show similar hair cell-
17 like structural features. Scanning electron micrographs (SEM) of the control and reprogrammed cochleae at
18 1000X (scale bar- 50 μ m). Arrows indicate individual reprogrammed hair cells. OHC: Outer hair cell region,
19 IHC: Inner hair cell region, GER: greater epithelia ridge region. SEM images at 50,000X show the kinocilium on
20 individual hair cells and side link structures connecting hair cell stereocilia as indicated by arrows.

21 **Figure 6: Single-cell transcriptomic analysis of control and reprogrammed cochlear cells at P15**

22 (A) FACS-based enrichment of cochlear cells targeted for transcription factor overexpression. The breeding
23 scheme with an experimental timeline is described followed by a representative whole mount image (bar: 50
24 μ m) from the Rosa26-GAP cochlea. The scheme is similar to that shown in Figure 3, except that tamoxifen is
25 injected to induce reprogramming at 8 days after birth, followed by analysis at day 15. All cells targeted for TF

1 overexpression are tdTomato positive (red), including reprogrammed hair cells (green). A representative FACS
2 scatter plot of dissociated induced cochlear cells is shown.

3 (B) UMAP plot for cells integrated and analyzed by scRNA-seq from all four genotypes (control, Rosa26-A,
4 Rosa26-GA, and Rosa26-GAP) purified in (A). Each identified cluster has been labeled.

5 (C) Genotype-wise UMAP plots highlighting the contribution of cells from each genotype in every identified
6 cluster.

7 (D) Schematic of the organ of Corti cross-section at P15. Unique cell types have been color-coded and
8 correspond to cluster colors in (B) and (C).

9 (E) Gene ontology analysis of the top differentially expressed genes in reprogrammed hair cells from each
10 condition (with respect to their expression in other cell clusters for that genotype). A list of ~200 significantly
11 expressed genes ($p < 1.00E^{-02}$) was analyzed and GO terms (Biological process, Cellular component,
12 Molecular function; $-\log_{10}(p\text{-value}) > 1$) are represented.

13 **Figure 7: GLAST+, SOX2+ supporting cells are induced adjacent to reprogrammed hair cells in the GER**

14 (A) Control and reprogrammed cochleae immunostained for markers specific to inner phalangeal and border
15 cells (GLAST), a general supporting cell marker (SOX2), pillar and Deiters' cells (PROX1), and the hair cell
16 marker, Myosin VIIA. The reprogrammed hair cell region is indicated (line; eHC – ectopic hair cells). Images
17 show 16 μm sections of the organ of Corti (control and reprogrammed). Scale bar: 50 μm .

18 (B) Differentially expressed genes from our P1-P8 scRNA-seq experiments in reprogrammed GLAST+
19 supporting cells are compared to control inner phalangeal/border cells. Volcano plots show common
20 upregulated genes *Cryab*, *Ccnd1*, *Rcn1*, *Hes5*, and downregulated genes *Lum*, *Ecrq4*, *Gsn*, *Clu* (GER specific
21 genes).

22 (C) Notch pathway genes are upregulated in the reprogrammed GLAST+ cells and hair cells in response to
23 transcription factor induction at P8. UMAP plot of cells integrated from all genotypes is shown with the
24 reprogrammed hair cells (red) and GLAST positive supporting cells (green). Average \log_{10} fold change in the

1 expression of supporting cell-specific Notch genes – *Ccnd1*, *Hes5*, *Lfng*, *Jag1*, *Hes1*, *Notch1*, *Cdkn1a*, *Nrarp*,
2 *Hey1*, *Gata3*, *Hes6*, *Heyl* and hair cell-specific Notch genes – *Dll3*, *Jag2*, *Dlk2* is represented.

3 **Figure 8: Rosa26-GAP reprogramming from day 8 to day 15 induces ectopic GLAST+ supporting cells**
4 **and up-regulates some hair cell genes in endogenous supporting cells**

5 (A) Control and reprogrammed cochleae immunostained for markers specific to inner phalangeal and border
6 cells (GLAST), a general supporting cell marker (SOX2), and a hair cell marker, Myosin VIIA. A reprogrammed
7 GLAST positive supporting cell in Rosa26-GAP condition is indicated with arrows. Images show a 16 µm
8 section of the organ of Corti (control and reprogrammed). Scale bar: 50 µm.

9 (B) Single-cell RNA seq analysis of supporting cells under reprogramming conditions (induction at day 8,
10 analysis at day 15). Volcano plots show that several hair cell-specific genes and Notch pathway genes are
11 upregulated by reprogramming factors, while several supporting cell genes are downregulated

12 **Figure 9: Multiomic analysis of 1 and 8 day old mouse cochlea shows a loss of epigenetic accessibility**
13 **of hair cell loci in GER and supporting cells.**

14 (A) Clustering of P1 and P8 cochlear cells on the basis of scRNA-seq, scATAC-seq and weighted-nearest
15 neighbor analyses. Different cochlear cell types can be resolved at both ages. IPh: Inner phalangeal cells;
16 MGER: Medial greater epithelial ridge; LGER: Lateral greater epithelial ridge; IHC: Inner hair cells; OHC: Outer
17 hair cells; GER: Greater Epithelial Ridge; BC: Border cells; DC1 and 2: Deiters' cells

18 (B) Heat map showing ATAC-seq peaks of 1627 distal regulatory elements identified in hair cell gene loci.
19 ATAC-seq data was extracted from day 1 and day 8 GER cells, and inner phalangeal and border cells.

20 (C) Examples of changes in the accessibility of three hair cell loci (*Hes6*, *Myo3b*, *Pou4f3*) in GER cells and
21 supporting cells in P1 and P8 mouse cochlea, measured by scATAC-seq. H3K4me1 data for each locus is
22 taken from Tao et al., (2021). Reductions in accessibility can be seen in all three loci between P1 and P8.

23

24

25

1 SUPPLEMENTARY FIGURES

2 **Figure 1, Supplementary Figure 1: Validation of transcription factor expression in ES cell lines used to** 3 **generate *ROSA26*-targeted mice, and cochlear expression of the *Sox8-CreER* line**

4 (A) Overexpression of the *ROSA-A*, *ROSA-GA*, and *ROSA-GAP* transcription factor combinations from the
5 *Rosa26* locus was verified by culturing ES cells used to generate the three lines of mice with membrane-
6 soluble TAT-Cre. Western blotting was performed after 48h with antibodies specific to ATOH1 (lane 1), GFP
7 (lane 2), POU4F3 (lane 3), and GAPDH (loading control; lane 4).

8 (B) Validation of the *Sox9-CreER* transgenic mice by crossing them to the *Ai3* *ROSA-EGFP* reporter line. The
9 left panels show immunostaining for SOX9 protein (green) and Myosin VIIA (red) in the P8 control. The right
10 panels show EGFP reporter expression (green) in the *Rosa26-EGFP* cochlea at P8 following tamoxifen
11 administration at P1. Images show 16 μm sections and 200 μm lengths of cochlear whole mounts. Scale bar:
12 50 μm .

13 **Figure 1, Supplementary Figure 2: Reprogrammed hair cells at neonatal ages can survive until at least** 14 **P15**

15 Reprogrammed hair cells obtained by administering tamoxifen at P1 survive until at least P15. They are not
16 subject to the apoptosis-mediated GER remodeling event that normally occurs between day 7 and day 15
17 (Peeters et al., 2015). Images show 200 μm lengths of P15 control and experimental cochleae immunostained
18 for Myosin VIIA (red) and fluorescently labeled phalloidin (green).

19 **Figure 2, Supplementary Figure 1: Transcription factor induction at P1 does not influence cell** 20 **proliferation in the reprogrammed cochlea**

21 Control and *Rosa26-A* animals received tamoxifen (25mg/kg body weight) at P1, EdU (50mg/kg body weight)
22 at regular intervals (P3, P5, P7 – twice per day). Animals were sacrificed at P8 for histological analysis. B: EdU
23 incorporation (green) was observed only in cells of the spiral ganglion neuron and basal lamina regions, but not
24 the organ of Corti (apex, middle, and base) in control and *Rosa26-A* animals. Images are from stained 16 μm
25 sections with Myosin VIIA (red) indicating hair cells. No Edu+/ Myosin VIIA + hair cells can be seen in either
26 control or experimental animals. Scale bar: 50 μm . C: Lower power images of the temporal bones analyzed at

1 P8 show that in addition to the SGN and basal lamina regions, extensive proliferation is observed in most parts
2 of the temporal bone except for the cochlea epithelium.

3 **Figure 3, Supplementary Figure 1: Examples of hair cell and LGER marker genes confirm cluster**
4 **assignments in P8 cochlear cell clusters**

5 UMAP plots (all four genotypes integrated) highlighting reprogrammed hair cell (RHC; red) and lateral GER cell
6 (LGER; yellow) clusters. Violin plots show normalized log-transformed expression values for hair cell marker
7 genes *Pou4f3*, *Pvalb*, *Lhx3*, and LGER marker genes *Pla2r1*, *Dgkb*, *Ces1d* in the two clusters of interest.

8 **Figure 4, Supplementary Figure 1: Validation of Sox9-CreER activity in the cochlea from P8 to P15 and**
9 **survival of reprogrammed hair cells from P15 to P29.**

10 (A) Immunostaining for SOX9 (green) and Myosin VIIA (red) in the P8 control cochlea shows widespread
11 SOX9 protein expression throughout the cochlear duct (left panel). The right panel shows Sox9-CreER; ROSA-
12 EGFP mice that received tamoxifen at P8 and analyzed at P15. Most of the cochlear duct is labeled, apart from
13 parts of the GER that undergo remodeling between P7 and P15. Images show 16 μm sections at 20x. Scale
14 bar: 50 μm .

15 (B) Reprogrammed Rosa26-GAP hair cells obtained by administering tamoxifen at P8 show ectopic hair cells
16 in the LGER region at P15, P23, and P29. By P29, most of the ectopic hair cells have organized actin bundles,
17 revealed by enhanced phalloidin staining in the ectopic Myosin VIIA cells. Images show 200 μm lengths of P15,
18 P23, P29 control, and Rosa26-GAP cochleae immunostained for Myosin VIIA (red) and fluorescently labeled
19 phalloidin (green).

20 **Figure 6, Supplementary Figure 1: Examples of hair cell and supporting cell marker genes confirm**
21 **cluster assignments in P15 cochlear cell clusters**

22 UMAP plots (all four genotypes integrated) highlighting the hair cell (HC; red) and supporting cell (SC; green)
23 clusters. Violin plots show normalized log-transformed expression values for hair cell marker genes *Pou4f3*,
24 *Pvalb*, and SC marker genes *GLAST*, *Lfn3* in the two clusters.

25

1 **Figure 7, Supplementary Figure 1: Use of the a second Cre line, Lfng-CreER, confirms that pillar and**
2 **Deiters' cells do not get reprogrammed into hair cell-like cells in response to transcription factor**
3 **overexpression.**

4 (A) Lfng-CreER mice crossed to ROSA-EGFP reporter mice show most supporting cells are labeled when
5 induced with tamoxifen at P1 and analyzed at P8. A representative image of a 200µm cochlear length is shown
6 with the reporter (green), hair cells (red – Myosin VIIA, upper panel; and phalloidin, lower panel), and DAPI
7 (magenta).

8 (B) Control mice and Rosa26-A, Rosa26-GA, and Rosa26-GAP received tamoxifen at P1 or P8 and were
9 analyzed 7 days later. Samples were labeled for Myosin VIIA (red) and Phalloidin (green). 200µm lengths are
0 shown in all conditions. No ectopic hair cells are seen in the pillar or Deiters' cell regions in any condition.

1 Scale bar: 50 µm.

2 **Figure 8, Supplementary Figure 1: Transcription factor induction at P8 does not influence cell**
3 **proliferation status in the control and reprogrammed cochlea at P15**

4 Control, Rosa26-A, Rosa26-GA, and Rosa26-GAP animals received tamoxifen (25mg/kg body weight) at P8
5 and EdU (50mg/kg body weight) at regular intervals (P10, P12, P14 – twice per day). Animals were sacrificed
6 at P15. EdU incorporation (green) was observed in a small number of mesenchymal cells of the temporal bone
7 wall in all four genotypes/samples at this age, but no labeling is seen in the organ of Corti. Images are from 16
8 µm sections stained with Myosin VIIA (red) and DAPI (magenta).

9 **Figure 9, Supplementary Figure 1: Endogenous Pou4f3 expression can be induced in 1 day old, but not**
10 **8 day old cochleae by reprogramming with Atoh1**

11 A) Control and Rosa26-A animals were induced with tamoxifen at P1 or P8. Immunostaining for POU4F3 three
12 days later at P4 (top panel) and P11 (bottom panel) revealed positive expression in the neonatal GER cells but
13 not in the 11 day old samples. These cells were confirmed to be targeted for *Atoh1* overexpression by the
14 *Sox9-CreER*, verified by staining for tdTomato expression in the control and Rosa26-A mice. Images show 16
15 µm sections at 20x. Scale bar: 50 µm. B) ATAC-seq data and H3K4me1 data from Figure 9C, combined with
16 ATOH1 CUT&RUN data from E17.5 hair cells (Tao et al, 2021). ATOH1 binding peaks are accessible in GER

- 1 cells, inner phalangeal cells and border cells and Deiters' cells at P1, but significantly less accessible at P8. C)
- 2 Heat map of ATOH1 binding sites in E17.5 hair cells, viewed for all 1627 distal regulatory elements identified
- 3 as being differentially accessible in the P1 vs P8 multi-omic analysis in Figure 9B. Many of these hair cell
- 4 enhancers are bound by ATOH1.

1 **SOURCE DATA**

2

3 **Source data 1 for Figure 1 – Supplementary Figure 1A**

4

5 Overexpression of the ROSA-A, ROSA-GA, and ROSA-GAP transcription factor combinations from the
6 Rosa26 locus was verified by culturing ES cells used to generate the three lines of mice with membrane-
7 soluble TAT-Cre. Western blotting was performed after 48h with antibodies specific to ATOH1, GFP, POU4F3 ,
8 and GAPDH as a loading control. The raw blots are shown.

9

0 **Source data 2 for Figure 1 – Supplementary Figure 1A**

1

2 Overexpression of the ROSA-A, ROSA-GA, and ROSA-GAP transcription factor combinations from the
3 Rosa26 locus was verified by culturing ES cells used to generate the three lines of mice with membrane-
4 soluble TAT-Cre. Western blotting was performed after 48h with antibodies specific to ATOH1, GFP, POU4F3 ,
5 and GAPDH as a loading control. The raw blots are shown with labels attached to indicate the relevant bands
6 and the conditions used.
