34 **SUMMARY:**

35 Glioblastoma remains a deadly cancer driven by invasion of tumor cells into the
36 brain. Transcriptomic analyses have revealed distinct molecular subtypes, but
37 mechanistic differences that explain clinical differences are not clear. Here, we show
38 that, as predicted by the motor-clutch model for cell migration, mesenchymal glioma
39 cells are more spread, generate larger traction forces, and migrate faster in brain tissue
40 compared to proneural cells. Despite their fast migration and comparable proliferation
41 rate in vitro, mice with mesenchymal tumors live longer than mice with proneural
42 tumors, which was correlated with an immune response in the mesenchymal mice that
43 included T cell-mediated killing of cancer cells, similar to human tumors. Thus,
44 mesenchymal tumors have aggressive migration, but are relatively immunologically 'hot'
45 which suppresses net proliferation. These two features counteract each other and may
46 explain the lack of a strong survival difference between subtypes clinically, while also
47 opening up new opportunities for subtype-specific therapies.

48 INTRODUCTION:

49 Glioblastoma (GBM: WHO grade IV primary brain tumor) progression can be
50 characterized in terms of tumor growth and spreading, two key parameters which are
51 influenced by many of the hallmarks of cancer (Hanahan and Weinberg, 2011). In GBM,
52 tumor spreading is driven by tumor cells' ability to infiltrate healthy brain parenchyma,
53 which prevents complete surgical resection and results in tumor recurrence (de Gooijer
54 et al., 2018; Hoelzinger et al., 2007; Lefranc et al., 2005). Molecular and genetic
55 analyses of human GBM have identified at least three distinct molecular subtypes:
56 proneural, classical, and mesenchymal (Phillips et al., 2006; Verhaak et al., 2010; Wang
57 et al., 2017). These subtypes were shown to strongly correlate with specific genetic
58 alterations (Mesenchymal: *NF1* loss; Classical: *EGFRvIII*; Proneural: *PDGFRA*) and
59 cellular developmental states (Nefitel et al., 2019; Patel et al., 2014; Verhaak et al.,
60 2010; Wang et al., 2017). Despite accumulating evidence of distinct transcriptomic and
61 genetic signatures, the characteristic mechanistic differences between such signatures,
62 if any, have not been identified. As a result, it remains unclear how knowledge of the
63 different subtypes should inform clinical decisions.

64 One intriguing correlate of subtype is the level of CD44 expression, a cell surface
65 protein expressed on tumor and immune cells, which is known to play a role in cancer
66 progression across a variety of cancers including GBM (Bhat et al., 2013; Klank et al.,
67 2017; Mao et al., 2013; Mooney et al., 2016; Naor et al., 2002; Nefitel et al., 2019;
68 Ozawa et al., 2014; Pietras et al., 2014; Toole, 2009; Wang et al., 2017). In GBM, we
69 previously showed that CD44 expression is a prognostic marker with a biphasic
70 dependence: better outcomes are observed at both lower and higher levels of CD44

71 while poorer outcomes are observed at intermediate levels, an example of optimality
72 and the ‘goldilocks’ phenomenon (Klank et al., 2017). In animal models, CD44
73 expression has further been shown to correlate with glioma cell migration in a biphasic
74 relationship with a peak migration rate at intermediate expression level, which also
75 correlated with the minimum in survival in both the animal model and human GBM
76 (Klank et al., 2017). In addition, *CD44* transcript levels are shown to vary across GBM
77 molecular subtypes with elevated expression in mesenchymal tumors (Phillips et al.,
78 2006; Pietras et al., 2014; Verhaak et al., 2010). *CD44* expression in the mesenchymal
79 tumors is, on average, closer to the *CD44* level that corresponds to the minimum in
80 patient survival than the proneural subtype (Klank et al., 2017). As an adhesion
81 molecule, CD44 engages the extracellular matrix with the actin cytoskeleton through
82 adapter proteins to mediate cell migration (Toole, 2009). This suggests that
83 mesenchymal cells have a near-optimal level of CD44 adhesion molecules to serve as
84 molecular “clutches” that resist myosin II motor forces, allowing them to migrate faster
85 than proneural cells which on average have a lower, suboptimal level of CD44 clutches
86 (see Figure 2B and 4E in Klank *et al.*, 2017). This could then explain the slightly worse
87 outcomes for mesenchymal patients and higher cell migration and invasion (Wang et
88 al., 2017; Yoshida et al., 2012). In addition, it would predict that mesenchymal cells
89 would have larger cellular spread area, be more polarized, and generate more traction
90 force as they migrate. More generally, lower CD44 is indicative of an epithelial state and
91 higher CD44 indicative of a mesenchymal state (Bloushtain-Qimron et al., 2008; Polyak
92 and Weinberg, 2009), and so an increase in myosin motors and adhesions, either

93 integrin- or CD44-mediated, may be driving the epithelial-to-mesenchymal transition
94 (EMT) in a variety of cancers such as breast cancer (Mekhdjian et al., 2017).

95 Based on these previous results, we tested the hypothesis that a key mechanistic
96 difference between GBM molecular subtypes is that proneural cells are slow migrating
97 and mesenchymal cells are fast migrating. To address this question, we generated
98 animal models recapitulating the transcriptomic signatures of human mesenchymal and
99 proneural GBM in an immune competent background using perturbations of known
100 GBM oncogenic pathways. Specifically, mesenchymal and proneural-like tumors were
101 driven by SV40-large T (LgT) antigen, to mimic common inhibition of p53 and Rb
102 signaling found in GBM (Ahuja et al., 2005; McLendon et al., 2008), in combination with
103 either NRAS^{G12V} (NRAS) or PDGFB (PDGF), respectively, which resulted in
104 mesenchymal or proneural transcriptomic features with only a single genetic change
105 required to switch subtypes in a wild type mouse background. As predicted, *CD44*
106 expression was higher in NRAS-driven tumors and, consistent with our simulation
107 predictions, *ex vivo* brain slice live imaging showed NRAS tumor cells migrate faster
108 than PDGF tumor cells, and exhibit greater spreading, polarization, and force
109 generation as well. Despite increased migration, the NRAS cohort had better survival
110 than PDGF which was attributed to enhanced antitumoral immune response in NRAS
111 tumors, consistent with increased immune cell infiltration in human mesenchymal GBM
112 (Doucette et al., 2013; Hara et al., 2021; Wang et al., 2021, 2017). Overall our work
113 identified a clinically actionable difference in migration mechanics between GBM
114 subtypes and establishes an integrated biophysical modeling and experimental

- 115 approach to mechanically parameterize and simulate distinct molecular subtypes in
116 preclinical models of cancer.

117 **RESULTS:**

118 **Genetically induced high-grade glioma mouse models recapitulate the** 119 **transcriptomic signatures of mesenchymal and proneural GBM**

120 To characterize the mechanics of GBM subtypes, we utilized the *Sleeping*
121 *Beauty* (SB) transposon-based gene transfer system to induce high grade gliomas in
122 immunocompetent FVB/NJ-strain mice (Calinescu et al., 2015; Klank et al., 2017;
123 Koschmann et al., 2016; Núñez et al., 2019; Wiesner et al., 2009). Constructs of
124 plasmids carrying SB transposons with oncogenic driver transgenes (SV40-
125 LgTA+NRAS^{G12V} or SV40-LgTA+PDGFB; here termed NRAS and PDGF, respectively)
126 were used to model mesenchymal and proneural GBM tumors, respectively (Figure 1A).
127 DNA plasmids carrying an SB transposon with encoded firefly luciferase and green
128 fluorescent protein (GFP) transgenes, and expressing SB transposase were co-injected
129 to allow for confirmation of successful gene transfer, detecting tumor development and
130 monitoring tumor growth using bioluminescence imaging (BLI) and single cell tracking
131 using fluorescence microscopy. Similar to human GBM, histological sections from these
132 tumors exhibited highly mitotic tumor cells, necrosis, anaplasia, and perivascular
133 infiltration and proliferation, (Figure 1B).

134 To assess whether the NRAS and PDGF tumors recapitulated the mesenchymal
135 and proneural subtypes, respectively, we performed cross-species transcriptomic
136 analysis using bulk RNA sequencing data from mouse and human tumors. Bulk RNA
137 sequencing was performed on tumor tissues from both cohorts and on normal brain
138 tissues (NBT) (NRAS N=4, PDGF N=4, and NBT N=3). IDH-WT human GBM
139 transcriptomic profiles were retrieved from Broad GDAC Firebrowse (Brennan et al.,

140 2013). Unsupervised hierarchical clustering of the mouse dataset (Table S1) revealed
141 clear differences between normal tissue and tumor tissue and between NRAS and
142 PDGF tumors (Figure S1A). Not surprisingly, gene ontology enrichment analysis, using
143 *EnrichR* (Kuleshov et al., 2016), showed an enrichment of cell cycle related processes
144 in tumor tissue specific gene cluster (817 genes) (Figure S1B) and neuronal processes
145 in normal tissue cluster (1722 genes) (Figure S1D). Interestingly, the NRAS-specific
146 cluster (1327 genes) was enriched with cytokine-mediated signaling and inflammatory
147 response processes (Figure S1C).

148 To determine whether any variations observed between the two mouse cohorts
149 were also present in human tumors, unsupervised hierarchical clustering was performed
150 on both mouse and human tumor datasets and clusters were independently identified in
151 both datasets (Table S2). Three and 10 gene clusters were identified in both mouse and
152 human datasets, respectively, as shown in Figure 1C. We identified mouse cluster MC1
153 (n=1534 genes) as being significantly enriched in genes found in human cluster HC1
154 (n=1186 genes, $p < 1 \times 10^{-15}$), MC2 (n=414 genes) is significantly enriched in genes
155 found in HC2 (n=1098 genes, $p < 1 \times 10^{-15}$), and MC3 (n=232 genes) is significantly
156 enriched in genes enriched in HC4 (n=432, $p < 1 \times 10^{-15}$). These results show that
157 conserved transcriptomic patterns distinguish subtypes of both mouse and human
158 tumors.

159 To assess whether the transcriptional patterns present in the mouse tumor
160 models represent previously described GBM subtypes, we compared the expression of
161 identified mouse gene clusters within human GBM subtypes. We found that MC1, which
162 is enriched in NRAS tumors, is significantly enriched in human mesenchymal GBM

163 relative to proneural and classical GBMs (Figure 1D). In contrast, MC3, which is
164 enriched in PDGF tumors, is significantly enriched in proneural GBM relative to
165 mesenchymal and classical GBMs (Figure 1D). Furthermore, we found the expression
166 of known mesenchymal and proneural genes and gene signatures are relatively
167 elevated in NRAS and PDGF tumors, respectively (Figure 1E, 1F and S2). These
168 results demonstrate that NRAS and PDGF tumors transcriptionally resemble
169 mesenchymal and proneural GBMs, respectively.

170

171 **Motor-clutch modeling of cell migration predicts NRAS/Mesenchymal tumor cells**
172 **will migrate faster, have larger cell spread area, and generate more force than**
173 **PDGF/Proneural tumor cells**

174

175 To examine tumor cell migration, we used our cell migration simulator
176 (Bangasser et al., 2017; Klank et al., 2017) to predict migration phenotypes in response
177 to gene expression changes. The cell migration simulator is based on the motor-clutch
178 model which incorporates actin-based protrusion dynamics, mass conservation, and
179 force balances to reproduce cell polarization and random motility in 1D and 2D
180 compliant microenvironments (Bangasser et al., 2013, 2017; Chan and Odde, 2008;
181 Estabridis et al., 2018; Hou et al., 2019; Klank et al., 2017; Liu et al., 2019; Prah et al.,
182 2018, 2020). The number of adhesion/clutches and motors are key determinants of cell
183 migration, with a relative balance being essential for efficient migration (Bangasser et
184 al., 2013, 2017; DiMilla et al., 1991). Using a set of 54 cell migration genes expressed in
185 the human U251 GBM cell line (Bangasser et al., 2017), NRAS tumors significantly
186 upregulate transcription of adhesion and adapter genes (Figure S3A). A similar set of
187 genes was also significantly upregulated in MES relative to PN GBM (Figure S3B). Both

188 NRAS and MES tumors upregulated *CD44* and its cognate adhesion adapter gene
189 moesin (*MSM*), which mechanically links the CD44 cytoplasmic tail to F-actin (Fehon et
190 al., 2010; Freeman et al., 2018; Legg and Isacke, 1998; Ponta et al., 2003; Toole, 2009;
191 Tsukita et al., 1994; Yonemura, 1998). Notably, the levels of myosin motor genes were
192 not differentially expressed in the mouse dataset, while, in the human dataset, *MYH9*
193 and *MYO1C* were modestly upregulated in MES tumors but to a lesser degree than
194 adhesion molecules (Figure S3B). These results suggest NRAS/Mesenchymal tumor
195 cells have a higher number of adhesion/clutches than PDGF/Proneural tumor cells and
196 little to no change in the number of motors.

197 Based on these results, we simulated the effect of *CD44* expression level on cell
198 migration by simply adjusting the number of adhesion bonds (number of clutches, N_c) in
199 the model (Bangasser et al., 2017; Klank et al., 2017). We used low clutches relative to
200 motors (low adhesion) to simulate PDGF/Proneural cells and a medium level of clutches
201 that balanced the number of motors (optimal adhesion) to simulate NRAS/Mesenchymal
202 cells (Figure 2A). Our simulations show that lowering the number of adhesions,
203 representing the PDGF/Proneural case, results in reduced cell migration, force
204 transmission, cell spread area, and cell polarization due to an insufficient number of
205 clutches relative to the number of motors, as shown in Figure 2. In the case where the
206 number of clutches and motors are balanced, representing the NRAS/Mesenchymal
207 case, where the number of adhesions is increased while holding the number of motors
208 constant, simulated cells recover their ability to migrate, transmit forces, spread, and
209 polarize across a range of substrate stiffnesses. Consequently, simulation results
210 predict that NRAS/Mesenchymal tumor cells will migrate faster than PDGF/Proneural

211 tumor cells due to increase of adhesion (i.e. CD44) expression in NRAS/Mesenchymal
212 tumors and not due to small difference in molecular motor expression (Figure S3A and
213 S3B). In addition, due to their higher number of clutches and balanced motor-clutch
214 ratio, NRAS/Mesenchymal tumor cells are predicted to generate higher force, have
215 larger spread area, and be more polarized.

216

217 **NRAS/Mesenchymal tumor cells migrate faster than PDGF/Proneural tumor cells** 218 **in brain tissue**

219 To test our model prediction that NRAS/Mesenchymal cells migrate faster than
220 PDGF/Proneural cells, we performed live cell imaging on tumor bearing mouse brain
221 slices using confocal microscopy. Time-lapse images of GFP-positive tumor cells were
222 used to track single cell migration and generate single cell trajectories. As shown in
223 Figure 3A, 3B and Video S1, NRAS/Mesenchymal tumor cells appeared qualitatively to
224 move farther, have larger spread area, and polarize to a greater extent than
225 PDGF/Proneural tumor cells. Quantitative analysis of single cell trajectories confirmed
226 that NRAS/Mesenchymal tumor cells have a higher random motility coefficient than
227 PDGF/Proneural tumor cells ($30.1 \mu\text{m}^2 \text{hr}^{-1}$ vs $2.5 \mu\text{m}^2 \text{hr}^{-1}$, $p < 0.001$; see Figure 3C and
228 S4A). In addition, morphological analysis of tumor cells revealed cell spread area and
229 cell aspect ratio (i.e. polarization) are also higher in NRAS/Mesenchymal tumor cells
230 than PDGF/Proneural tumor cells ($406.6 \mu\text{m}^2$ vs $235.8 \mu\text{m}^2$, $p < 0.00001$ and 2.1 vs 1.7 ,
231 $p < 0.001$, respectively, see Figure 3D, 3E, S4B and S4C). As predicted by our modeling,
232 and the hypothesis that NRAS/Mesenchymal has balanced motors and clutches while
233 PDGF/Proneural lacks sufficient clutches, we find NRAS/Mesenchymal cells migrate
234 faster, are more spread, and are more polarized than PDGF/Proneural cells.

235

236 **Migration phenotype is species and tumor microenvironment independent**

237 To determine whether migration phenotype is cancer cell intrinsic as predicted by
238 our modeling and not due to microenvironment differences, we generated three primary
239 mouse lines grown as neurospheres from each cohort to investigate their migration
240 phenotype outside their tumor microenvironment. Organotypic mouse brain slice culture
241 was used to image tumor cell migration in healthy mouse brain slices (Liu et al., 2019).
242 Dissociated mouse tumor cells were plated and allowed to invade and migrate in
243 healthy mouse brain slices. Figure 4A shows representative fluorescence images of
244 primary isolated cells in organotypic slice culture. Time-lapse imaging was used to track
245 single cells and quantify their migration rates. Consistent with the *ex vivo* migration in
246 intact tumor-bearing brain slices, random motility coefficient in normal mouse brain
247 tissue is higher for primary NRAS/Mesenchymal tumor cells than primary
248 PDGF/Proneural tumor cells ($131.4 \mu\text{m}^2 \text{hr}^{-1}$ vs $31.3 \mu\text{m}^2 \text{hr}^{-1}$, $p < 0.00001$; Figure 4B,
249 S4D and Video S2). The area of cell spreading is also higher in primary
250 NRAS/Mesenchymal tumor cells than PDGF/Proneural ($1075.1 \mu\text{m}^2$ vs $838.8 \mu\text{m}^2$,
251 $p < 0.001$; Figure 4C and S4E). Furthermore, cell aspect ratio, the ratio of major and
252 minor axis of a fitted ellipse, was trending higher in NRAS/Mesenchymal tumor cells
253 than PDGF/Proneural but did not reach statistical significance (Figure 4D and S4F).

254 To assess the relevance of these results to human GBM, we tested the migration
255 phenotype of six patient-derived xenograft (PDX) lines (three mesenchymal and three
256 proneural) using the organotypic mouse brain slice culture. Figure 4E shows
257 representative fluorescence images of PDX cells in organotypic slice culture. We found

258 mesenchymal PDX cells migrate faster than proneural PDX cells ($43. \mu\text{m}^2 \text{hr}^{-1}$ vs 8.8
259 $\mu\text{m}^2 \text{hr}^{-1}$, $p < 0.00001$; Figure 4F, S4G and Video S3). In addition, similar to our mouse
260 models, mesenchymal PDX cells have larger area of cellular spreading and aspect ratio
261 relative to proneural PDX cells ($701.7 \mu\text{m}^2$ vs $564.6 \mu\text{m}^2$, $p < 0.00001$ and 2.3 vs 2.0 ,
262 $p < 0.001$, respectively, see Figure 4G, S4H, 4H and S4I).

263

264 **Traction strain energy is larger for NRAS/Mesenchymal cells than for**
265 **PDGF/Proneural cells, consistent with model predictions**

266 In addition, cell migration simulations predict NRAS/Mesenchymal tumor cells
267 would have increased force generation as a result of higher number of clutches
268 resulting in balanced myosin motors and clutches, relative to PDGF/Proneural tumor
269 cells which would have insufficient clutches relative to motors (Figure 2D). Using the
270 primary isolated mouse lines, traction force microscopy was used to measured traction
271 strain energy generated by tumor cells on polyacrylamide hydrogels (Bangasser et al.,
272 2017; Butler et al., 2002). Because transcriptomic analysis showed an overall higher
273 level of adhesion molecules in NRAS/Mesenchymal tumor tissues, including CD44 and
274 integrins, Type-I Collagen was used to coat polyacrylamide hydrogels (Figure S3A).
275 Because of the overall higher level of adhesion Consistent with model predictions,
276 NRAS/Mesenchymal tumor cells generate higher traction strain energy than
277 PDGF/Proneural tumor cells across different substrate Young's moduli (Figure 5A and
278 5B). Cell spread area is also higher in NRAS/Mesenchymal than PDGF/Proneural on
279 polyacrylamide hydrogels (Figure 5C). In addition, NRAS/Mesenchymal cells exhibit
280 stiffness sensitive cell spreading; cells on stiff substrate (4.6 and 9.3 kPa) were more

281 spread than on soft substrate (0.7kPa, $p < 0.00001$; see Figure 5C). Furthermore, we
282 also examined force generation of mesenchymal and proneural PDX cells in mouse
283 brain slices. Qualitative analysis of vasculature deformation is consistent with the model
284 prediction that mesenchymal PDX cells generate larger deformations relative to
285 proneural PDX cells, as shown in Figure 5D, 5E and Video S3.

286

287 **NRAS/Mesenchymal mice have better survival and slower tumor growth rate**

288 Since NRAS/Mesenchymal cells have nearly optimal *CD44* expression, and
289 therefore higher motility compared to PDGF/Proneural cells which have a suboptimal
290 low level of *CD44* expression (Klank et al., 2017), we asked whether the differences in
291 migration rate, morphology and force generation correlate with disease progression and
292 survival. Specifically, based on the faster migration in the NRAS/Mesenchymal cohort,
293 we expected that these mice would progress faster and die sooner than
294 PDGF/Proneural mice. To test this hypothesis, we measured survival times of tumor
295 bearing mice and found that, opposite to our expectation, the NRAS/Mesenchymal
296 cohort had better median survival than PDGF/Proneural cohort (NRAS N=21, PDGF
297 N=24, 65 days vs. 35 days, log-rank test, $p < 0.0001$; Figure 6A). To explain the
298 difference in survival, we quantified *in vivo* tumor growth using bioluminescence imaging
299 (BLI) of tumor-bearing mice. Consistent with their shorter survival, we found PDGF
300 tumors grew twice as fast as NRAS tumors (Slopes: 0.127 ± 0.01191 vs. 0.0716 ± 0.00343
301 $p < 0.001$, Figure 6B and 6C). Using mouse tumor neurospheres, we quantified mouse
302 primary tumor cell line proliferation rates *in vitro* and found no significant difference
303 between NRAS/Mesenchymal and PDGF/Proneural cells (Figure 6D). These results

304 imply that an additional factor, besides proliferation or migration, enables the
305 NRAS/Mesenchymal mice to live longer and their tumors to grow slower *in vivo* than
306 PDGF/Proneural mice.

307

308 **NRAS/Mesenchymal mice have increased immune response relative to**
309 **PDGF/Proneural mice**

310 Because mesenchymal GBMs are known to be relatively immunologically “hot” –
311 which presumably confers a survival benefit due to an antitumoral immune response-
312 relative to immunologically “cold” proneural GBMs (Doucette et al., 2013; Neftel et al.,
313 2019; Wang et al., 2017), we assessed the extent to which mouse NRAS/Mesenchymal
314 tumors induce an immunological response relative to PDGF/Proneural tumors and
315 normal brain tissues. Using our mouse transcriptomic dataset and previously published
316 GBM immune gene sets (Doucette et al., 2013), NRAS/Mesenchymal tumors were
317 found to have increased expression of both immune activators and suppressors gene
318 signatures similar to human mesenchymal GBM (Doucette et al., 2013), as shown in
319 Figure 7A and 7B. Specifically, expression of immune cell marker genes such as *Aif1*,
320 *Itgam* (microglia/macrophages) and *Cd3* (T cells) are elevated in NRAS/Mesenchymal
321 tumors relative to PDGF/Proneural tumors (Figure 7C upper panel) and in
322 mesenchymal GBMs relative to proneural and classical GBMs (Figure 7C lower panel).
323 Elevated expression of immune cell markers is indicative of increased immune cell
324 infiltration in mesenchymal tumors. Consistent with the transcriptomic findings, IHC
325 staining of NRAS/Mesenchymal and PDGF/Proneural tumor sections revealed
326 significant levels of immune cell infiltration, including both microglia/macrophages and

327 T-lymphocytes, in NRAS/Mesenchymal but much less so in PDGF/proneural tumors
328 (Figure 7D). Furthermore, increased immune infiltration and activity in
329 NRAS/Mesenchymal tumors was accompanied by increased cell killing as measured by
330 granzyme B and cleaved caspase-3 staining (Figure 7D). Image clustering analysis was
331 used to quantify CD3, IBA1, granzyme B, and cleaved caspase-3 staining, and
332 statistically significant differences were observed between NRAS/Mesenchymal and
333 PDGF/Proneural cohorts (Figure 7E-H). This anti-tumor response was also evident in
334 the three instances where NRAS mice developed tumors and tumor regression was
335 observed (Figure S5). Despite the anti-tumor immune response observed in
336 NRAS/Mesenchymal tumors, transcriptomic analysis also revealed elevated relative
337 expression of immune checkpoint genes including PDL1, CTLA4, and CD200R1 (Figure
338 S6). Thus, the NRAS/mesenchymal tumors, like human mesenchymal GBMs, are
339 relatively immunologically “hot” with evidence of both immune activation and immune
340 suppression, as well as evidence of cell killing. Altogether, the enhanced immune cell-
341 associated tumor cell killing provides a mechanism by which survival is extended in
342 NRAS/Mesenchymal tumors despite their enhanced migration speeds relative to
343 PDGF/Proneural tumors.

344

345 **Brownian dynamics simulations explain NRAS/Mesenchymal and**

346 **PDGF/Proneural tumor progression**

347 To quantitatively describe the interplay between tumor cell migration and
348 proliferation and anti-tumoral immune response in tumor growth, we developed a three-
349 dimensional (3D) Brownian dynamics tumor simulator (BDTS) based on our original 1D

350 Brownian dynamics simulator (Klank et al., 2018; Ray et al., 2018). The simulator takes
351 into account anti-tumoral immune cells that infiltrate tissue, migrate, proliferate,
352 encounter cancer cells, deliver cytotoxic agents, dissociate from cancer cells, undergo
353 exhaustion, and, eventually, undergo apoptosis (or egress to lymphatics) as shown in
354 Figure 8A. At the same time, cancer cells migrate, proliferate and undergo CTL-
355 mediated death in the presence of anti-tumoral immune cells in the case
356 NRAS/Mesenchymal tumors. In the case of PDGF/Proneural tumors, no anti-tumoral
357 immune cells were simulated. Figure 8B shows simulation output at day 0 and day 16,
358 which showed the observed behavior of overall faster growth of PDGF/Proneural
359 tumors. In the NRAS/Mesenchymal tumor simulations, cancer cells appear more
360 dispersed, whereas, in PDGF/Proneural simulations, cancer cells are less dispersed.
361 Simulated tumor growths were plotted in Figure 8C and shown in Video S4. Using the
362 parameters in Table S5, including the experimentally observed single cell migration
363 speeds and neurosphere proliferation rates, simulated tumors qualitatively recapitulate
364 the *in vivo* growth profile of NRAS/Mesenchymal and PDGF/Proneural tumors without
365 parameter adjustment (Figure 8C).

366 **DISCUSSION:**

367 Understanding glioma progression and the mechanism driving glioma cell
368 migration is critical for the design of effective therapies. Here we developed high-grade
369 glioma mouse models which capture the transcriptomic and the immune
370 microenvironment changes associated with human proneural and mesenchymal GBMs.
371 Using the mouse models and PDX lines, we defined a mechanistic difference in glioma
372 cell migration which highlights a functional characteristic of GBM molecular subtypes.
373 The migration difference was consistent with changes in cellular adhesion, notably by
374 *CD44*, but not molecular motors such as myosin II motors. This finding points toward an
375 anti-migratory therapy approach targeted against cellular adhesion as opposed to
376 myosin motors. With the negative Phase III clinical trial of the integrin-inhibitor,
377 Cilengitide for GBM (Stupp et al., 2014), it is possible that integrins may not be the
378 major adhesion molecules utilized by glioma cells to migrate but instead they could
379 utilize CD44. While anti-CD44 therapies have not been tried in GBM, an anti-CD44
380 monoclonal antibody therapy (RO5429083, Roche, Basel, Switzerland) has been
381 investigated in Phase I trials in patients with solid tumors and with AML (Menke-van der
382 Houven van Oordt et al., 2016; Vey et al., 2016). Therefore, an anti-CD44 therapy could
383 provide clinical benefits by slowing glioma migration.

384

385 Furthermore, the upregulation of CD44 in mesenchymal tumors is supportive of
386 the existing literature which defines CD44 as a marker of cancer stem cell and EMT
387 (Bloushtain-Qimron et al., 2008; Polyak and Weinberg, 2009; Ponta et al., 2003). During
388 EMT, cancer cells take a more mesenchymal migratory phenotype to allow them to

389 migrate through dense ECM and metastasize (Chaffer and Weinberg, 2011). Our
390 results associate enhanced migration in mesenchymal glioma cells with increased
391 traction forces due to increased adhesion molecules expression ‘clutches’ such as
392 CD44. Similarly, in breast cancer cells, TGF- β -induced EMT is associated with
393 increased traction forces and clutch number (Mekhdjian et al., 2017). Interestingly,
394 downregulation of NF1, a negative regulator of Ras, in epithelial breast cancer cells and
395 Schwann cells also induces expression of transcription factors related to EMT (Arima et
396 al., 2010). Moreover, in our study, NRAS^{G12V} expression was used to mimic NF1
397 downregulation and inactivation in mesenchymal GBM (Krusche et al., 2016; Verhaak et
398 al., 2010). Ras hyperactivation of MAPK pathway is required for EMT but not PI3K
399 activation by Ras (Janda et al., 2002). Altogether, our results implicate EMT in
400 enhanced glioma cell migration and force transmission associated with increased
401 molecular clutches through, and suggest upregulation of clutches, either integrins or
402 CD44, as a conserved feature of EMT across a range of cancers.

403 Despite the faster migration of the NRAS/Mesenchymal cells, the anti-tumoral
404 immune response within the NRAS/Mesenchymal mouse model is able to slow disease
405 progression and improve survival despite enhanced migration relative to the
406 PDGF/Proneural mouse model. Such an anti-tumor response could potentially be used
407 to slow disease progression and improve clinical outcome for GBM patients. In both
408 mouse and human GBM, mesenchymal tumors are immunologically ‘hot’ relative to the
409 immunologically ‘cold’ proneural tumors (Doucette et al., 2013; Wang et al., 2017).
410 Despite the presence of immune cells within mesenchymal tumors, immune
411 suppression leads to tumors ultimately prevailing against the anti-tumoral immune

412 response. Based on these findings, we propose an immune checkpoint inhibition
413 strategy, in combination with an anti-migratory therapy, targeting mesenchymal GBM
414 but not proneural GBM.

415 Our study utilizes an integrated, state of the art experimental approach to study
416 GBM progression and model GBM molecular subtypes by switching a single oncogenic
417 driver (NRAS^{G12V} ↔ PDGFB), in an immunocompetent background without the need for
418 genetically engineered mouse strains or further breeding. Using live cell and brain slice
419 imaging, we identify key mechanical differences between mesenchymal and proneural
420 tumor cells, with mesenchymal cells have larger cellular spread area, generate larger
421 forces, and migrate faster. The functional differences were all predicted by a motor-
422 clutch model for cell adhesion and migration where mesenchymal cells have an optimal
423 level of CD44-mediated adhesion (clutches) relative to myosin motors, while proneural
424 cells lack sufficient CD44 to match the myosin motor activity. Despite the faster
425 migration, NRAS/Mesenchymal mice live longer, consistent with the presence of an
426 anti-tumoral immune response that is lacking in PDGF/Proneural mice (Fig. 8D),
427 dynamics that are readily captured computationally with little parameter adjustment
428 using a 3-D Brownian dynamics tumor simulator (BDTS). Overall, this work establishes
429 an integrated *in vivo* genetic and biophysical modeling framework to connect animal
430 model and human transcriptionally-defined subtypes to fundamental mechanistic
431 understanding, which has the potential to enable a new modeling-centric approach to
432 clinical translation with application in a wide range of cancers (Brubaker and
433 Lauffenburger, 2020).

434

435 **MATERIALS AND METHODS:**

436 **Generation of mouse tumor models**

437 All animal studies were conducted according to guidelines approved by the
438 Institutional Animal Care and Use Committee at the University of Minnesota. All animals
439 were housed in a daily monitored animal facility. FVB/NJ strain of mice were used in this
440 study. Malignant gliomas were induced in neonatal mice by DNA plasmid injection into
441 the right lateral ventricle as described previously (Calinescu et al., 2015; Wiesner et al.,
442 2009). Briefly, neonatal mice were injected with 1 µg of plasmid DNA mixed with
443 polyethyleneimine (jetPEI, Polyplus, Berkeley, CA), and 5% dextrose in a total volume
444 of 2 µL at a rate of 0.7 µL/min. The following four plasmids were used (1:1:1:1) ratio:
445 empty vector, pT2/C-Luc/PGK-SB100, pT/CMV-LgTA_g-IRES-GFP, pT2/Cag-NrasV12
446 or pT2/Cag-mPDGF. Animals were monitored daily for morbidity by bioluminescent
447 imaging.

448

449 **Immunohistochemistry of mouse tumor sections**

450 Formalin fixed and paraffin embedded (FFPE) mouse brain tissues were used to
451 prepare 4 µm thick slides. FFPE tissue slides were stained with hematoxylin and eosin
452 (H&E) or IHC using standard methods. Table S6 contains a list of antibodies and
453 reagents used for antigen retrieval, blocking and detection.

454

455 **Quantification of IHC staining of mouse tumor sections**

456 Immunohistochemistry data was quantified by counting the number of pixels in
457 an image that were positively DAB stained. To avoid user bias and subjective counting,
458 k-means clustering was used to identify pixels representing areas of positive DAB,
459 hematoxylin staining, and background. In this implementation, every pixel in an
460 analyzed image is assigned to one of four clusters, each cluster representing a different
461 component in the image: positive DAB-stained areas (brown), positive hematoxylin
462 counter-stained areas (blue), unstained tissue (light blue), and background glass slide
463 (beige). Digital images of equal sizes (2000x2000 pixels) of DAB stained and
464 hematoxylin counterstained tumor samples were converted from RGB to the HSV color
465 model.

466 Using a custom written MATLAB algorithm, user input is used to define areas
467 representing the four components (positive DAB stain, hematoxylin counterstain,
468 unstained tissue, and background glass slide). These points are used as the initial
469 estimates for the centroid locations of each of the four clusters. The squared Euclidean
470 distance between each pixel's HSV coordinates and the HSV coordinates of each
471 cluster's centroid is computed. Each pixel is then assigned to the cluster with the
472 minimum squared Euclidean distance to the cluster centroid. Cluster centroids are
473 recalculated as the mean of the HSV coordinated of all current members. This process
474 is iterated until the centroid of each cluster is stable. The number of pixels in the positive
475 DAB-stained cluster is used to quantify percent positive pixels in Figure 7E-H.

476

477 **Transcriptional profiling of mouse tumors**

478 Mice were euthanized in a CO₂ chamber and perfused transcardially with isotonic
479 saline. Mouse brains were extracted and GFP goggle (#FHS/EF-2G2; BLS-ltd,
480 Budapest, Hungary) was used to dissect GFP-positive tumor tissues from NRAS and
481 PDGF mouse brains. Two matched normal brain tissues were collected from brain
482 regions away from the tumor and an additional normal brain tissue sample was
483 collected from a health FVB adult mouse. All samples were immediately placed in
484 *RNALater* solution (Sigma, St. Louis, MO) for 24 hours then flash frozen in liquid
485 nitrogen and stored in -80 °C for downstream processing. RNA extraction and
486 sequencing were performed at the University of Minnesota Genomics Center (UMGC,
487 Minneapolis, MN). RNA was extracted using *RNAeasy* Plus Universal Mini kit (Qiagen,
488 Venlo, Netherlands) and libraries were prepared using *TruSeq* stranded mRNA
489 (Illumina, San Diego, CA).

490 Next-generation sequencing was performed on the prepared RNA libraries using
491 an Illumina HiSeq 2500 device in high output mode and generated 51 bp reads with an
492 approximate depth of 20 million paired reads per sample. Mapping and expression
493 calculations were generated using the rnaseq-pipeline of Gopher-pipelines
494 (<https://bitbucket.org/jgarbe/gopher-pipelines>), which executed TopHat2 (Kim et al.,
495 2013) and Cuffnorm (Trapnell et al., 2010) using the UCSC mm10 version of the mouse
496 reference genome. Fastq files and the Cuffnorm output were deposited at Gene
497 Expression Omnibus (GSE161154).

498

499 **Human GBM transcriptomic data**

500 UNC RNASeqV2 level 3 expression (normalized RSEM) profiles of 171 samples
501 (TCGA-GBM) were retrieved from Broad GDAC Firebrowse (Brennan et al., 2013). IDH
502 status and subtype information were added to each sample based on the *Wang et al.*
503 classification (Wang et al., 2017). For downstream analysis, 147 IDH-WT samples were
504 used (57 Classical; 52 Mesenchymal; 38 Proneural).

505

506 **Clustering analysis of mouse and human expression profiles**

507 To analyze the transcriptional profiles of mouse and human datasets, a value of
508 0.1 was added to all FPKM and RSEM values to minimize the impact of inaccurate low
509 values (Scott et al., 2018). The expression data was log transformed and mean
510 centered and transcripts with Standard Deviation > 1 were clustered using average
511 linkage hierarchical clustering in MATLAB. Pearson correlation was used as the
512 similarity metric. A custom written MATLAB script was used to systematically identify
513 transcriptional clusters within each dataset. In mouse dataset, a correlation greater than
514 0.5 and > 100 transcripts were used to identify gene clusters. Whereas, in human
515 dataset, a correlation greater than 0.2 and >100 transcripts were used. Fisher's exact
516 test was used to compare cluster memberships in Figure 1C. All genes identified within
517 each cluster are listed in Table S2.

518 To quantify the relative expression of gene clusters in Figure 1D and subtype
519 gene signature set in Figure S2C and S2D, the average relative expression of each
520 gene set was computed for all samples. The average relative expression from each
521 sample was plotted and used to calculate mean relative expression within each mouse
522 cohort and within human GBM molecular subtype.

523

524 **Generation of mouse primary tumor lines**

525 For each line, a tumor bearing mouse was euthanized and transcardially
526 perfused with isotonic saline. Tumor tissue was collected and minced with a scalpel.
527 Minced tumor fragments were incubated with PBS for 15 min at 37 °C. Tumor fragments
528 were further dissociated by mixing them up and down using a 1000 µl micropipette.
529 Finally, tumor suspension was passed through a 40 µm sterile cell strainer (Thermo
530 Fischer Scientific, Waltham, MA) and filtrate was spun down and plated on a Matrigel
531 (354230; Corning, Corning, NY) coated T-75 flasks (Corning, Corning, NY) using NSC
532 media which consisted of DMEM/F12 (Gibco 11320033; Thermo Fischer Scientific,
533 Waltham, MA) with 1X B-27 supplement (Gibco 12587010, Thermo Fischer Scientific,
534 Waltham, MA) and 1X penicillin/streptomycin (Corning, Corning, NY). Twenty ng/ml
535 EGF (PeproTech, Rocky Hill, NJ) and FGF (PeproTech, Rocky Hill, NJ) were added to
536 the cell culture media every 2-3 days. Cells were cultured in a 37 °C 5% CO₂ incubator.
537 Once a confluent layer was achieved, cells were detached using 0.25% Trypsin EDTA
538 (Corning, Corning, NY) and frozen down for later use.

539 Once tumor lines were established, cells were grown as neurospheres using
540 NSC media and Ultra-Low Attachment 6-well plates (Corning, Corning, NY).
541 Neurospheres were dissociated using accutase (Innovative Cell Technologies, San
542 Diego, CA). In total, six different mouse primary tumor lines were established: three
543 NRAS and three PDGF.

544

545 **Patient-derived xenograft (PDX) cell line culture**

546 The patient-derived xenograft (PDX) cell lines were taken from the Mayo Clinic
547 GBM PDX collection (managed by Dr. Jann Sarkaria, Mayo Clinic, Rochester, MN).
548 Three mesenchymal PDX lines (GBM 16, 39 and 44) and three proneural PDX lines
549 (GBM 64, 80 and 85) were selected to study their migration in organotypic mouse brain
550 slice. Cells were cultured on Matrigel (354230; Corning, Corning, NY) coated tissue
551 culture flasks in a 37 °C 5% CO₂ incubator. NSC media was used to culture PDX cell
552 lines and 20 ng/ml EGF and FGF were added to the cell culture media every 2-3 days.

553

554 ***Ex vivo* confocal imaging of tumor-bearing brain slices**

555 Tumor-bearing mice were sacrificed when bioluminescence signals were around
556 5×10^7 radiance (p/sec/cm²/sr). Mice were euthanized in a CO₂ chamber and perfused
557 transcardially with isotonic saline. Mouse brains were extracted and kept in chilled
558 artificial cerebrospinal fluid (124 mM NaCl, 2.5 mM KCl, 2.0 mM MgSO₄, 1.25 mM
559 KH₂PO₄, 26 mM NaHCO₃, 10 mM glucose). Coronal brain slices of thickness 300 μm
560 were prepared using a vibratome (Leica Biosystems, Buffalo Grove, IL). Only one slice
561 was used for live-cell imaging. Isolectin GS-IB4 (Alexa Fluor 568 Conjugate; Molecular
562 Probes, Eugene, OR) was used to label the vasculature.

563 Before imaging, the slice was washed and transferred into a No. 0 glass bottom
564 35 mm culture dish (P35G-0-20-C; MatTek, Ashland, MA). A tissue culture anchor (SHD
565 42-15; Warner Instruments, Hamden, CT) was placed on top of the slice to prevent
566 movement during imaging. The slice was then imaged on a Zeiss LSM 7 Live swept-
567 field laser confocal microscope (Zeiss, Oberkochen, Germany) at 15-minute intervals for

568 up to 20 hours in humidified 5% CO₂ air at 37 °C. Images were collected with a 20x
569 objective lens (Plan-ApoChromat 20X, 0.8 NA, Zeiss, Oberkochen, Germany). The
570 number of Z stacks of several regions of interest was adjusted to ensure that the data
571 acquisition of one frame in the time series was completed under 15 minutes (10-20
572 planes with 10 µm z-step was typically used). Maximum intensity projections from
573 multiple Z stacks were used to generate 2D images for quantitative morphological and
574 trajectory analysis. Images were registered by an affine transformation using ImageJ
575 StackReg plug-in (École Polytechnique Fédérale De Lausanne) to account for stage
576 drift and tissue relaxation during time-lapse imaging.

577

578 **Live-cell imaging of tumor cells in organotypic brain-slice culture**

579 Healthy mouse brain slices were prepared using the same method as tumor-
580 bearing brain slices above. For experiments using GFP-positive mouse primary tumor
581 lines, neurospheres were dissociated using accutase (Innovative Cell Technologies,
582 San Diego, CA). The protocol of grafting cancer cells into the brain slice was described
583 in details in our previous publication (Liu et al., 2019). Briefly, after creating a single cell
584 suspension, 300,000 cells in 3 mL of media were plated onto the brain slice. The cells
585 were co-cultured with the brain slice for 4 hours at 37 °C and 5% CO₂ before imaging to
586 promote cell infiltration into the brain slice. Phenol-free NSC media +2% FBS (Gibco,
587 Thermo Fischer Scientific, Waltham, MA) was used. The slices (Isolectin GS-IB4
588 stained) were washed several times using cell culture media and transferred into a No.
589 0 glass bottom 6-well plate (P06G-0-20-F; MatTek, Ashland, MA). The slices were
590 imaged on a confocal microscope with a 10X objective lens (Plan-ApoChromat 10X,

591 0.45 NA, Zeiss, Oberkochen, Germany). Similar imaging protocol as mentioned above
592 was applied.

593 For PDX cells, 500,000 – 800,000 cells were stained using DiO membrane dye
594 (V22886; Thermo Fisher Scientific, Waltham, MA) for 5 minutes and then washed twice
595 before plating onto the brain slice inside a 35mm tissue culture dish. The grafting of the
596 cells to the brain slice was similar to the mouse primary cells described above. The
597 slices were imaged on a confocal microscope using a 20X objective lens (Plan-
598 ApoChromat 20X, 0.8 NA, Zeiss, Oberkochen, Germany). Similar imaging protocol was
599 applied.

600 For both mouse primary tumor cells and PDX cells, we also acquired the
601 maximum intensity projections from multiple Z stacks and performed image registration
602 for further analysis for cell migration and morphology. Images were registered by an
603 affine transformation using ImageJ StackReg plug-in (École Polytechnique Fédérale De
604 Lausanne) to account for stage drift and tissue relaxation during time-lapse imaging.

605

606 **Single cell tracking and morphology analysis**

607 Single cell migration was tracked as previously described using a custom-written
608 image segmentation algorithm in MATLAB (Bangasser et al., 2017; Klank et al., 2017).
609 Using cell centroid coordinates, the mean squared displacement (MSD) of the cell
610 trajectories over time was calculated using the time interval overlap method (Dickinson
611 and Tranquillo, 1993). To quantify the dispersion of cells, the MSD over time was used
612 to calculate the random motility coefficient μ according to the equation ($MSD(t)=4\mu t$;
613 assuming 2-D geometry). Using segmented cell regions, cell area and cell aspect ratio,

614 defined as the ratio between the major and minor axis length of a fitted ellipse, were
615 measured for each individual tracked cell. Distributions of random motility coefficients,
616 cell area and cell aspect ratio for the different conditions were compared using the
617 Kruskal-Wallis test, which is a non-parametric rank-based test.

618

619 **Bioluminescence imaging and analysis**

620 Animals were monitored for tumor development and progression using
621 noninvasive bioluminescence imaging. Oncogene-injected animals were injected
622 intraperitoneally with 100 μ l of 28.5 mg/ml luciferin (GoldBio, St. Louis, MO) prior to
623 imaging. Mice were then anesthetized using 3% isoflurane and imaged on an IVIS50
624 or IVIS100 instrument (Xenogen, Alameda, CA). Images were acquired ten minutes
625 after injection with five minutes exposure time (Xenogen LivingImage Software,
626 Alameda, CA). To avoid saturation, exposure time was reduced appropriately in fully
627 grown tumors and accounted for in the analysis. BL images were processed using a
628 custom written MATLAB algorithm where background signal was subtracted and pixels
629 away from the tumor were set to zero. BL signal from each animal was then normalized
630 to the initial time point when tumor was first detected.

631

632 **Quantification of proliferation of mouse primary tumor line**

633 To measure proliferation rate, 200,000 cells from each line were plated into an
634 ultra-low adhesion 6-well plate and grown as neurospheres. Growth factors were added
635 every 2-3 days. At day six, neurospheres were dissociated and cells counted. After

636 counting, the remaining cells were replated and resumed growing as neurospheres.
637 Cells were also counted and replated at day nine and day 13. Experiment was repeated
638 three times using each of five mouse primary tumor lines (three NRAS and two PDGF
639 tumor lines). For each replicate, the average cell count for each cohort was calculated
640 using the cell count from the different corresponding tumor lines.

641

642 **Traction force measurements**

643 Traction force measurements of mouse primary tumor lines were performed
644 using traction force microscopy on polyacrylamide gels embedded with 0.2 μm crimson
645 fluorescent beads (Thermo Fischer Scientific, Waltham, MA) and coated with Type-I
646 Collagen (Corning, Corning, NY). Collagen coated polyacrylamide gels of varying
647 Young's modulus were prepared as previously described (Bangasser et al., 2017; Wang
648 and Pelham, 1998). Briefly, 0.7, 4.6, and 9.3 kPa polyacrylamide polymer mixture with
649 fluorescent beads were cast onto a No. 0 glass bottom dish then coated with Type-I
650 Collagen using Sulfo-SANPAH (Thermo Fischer Scientific, Waltham, MA). Mouse
651 primary tumor cells were dissociated from neurospheres and plated on prepared gels at
652 low density (1-5 cells/ mm^2) using NSC media +2% FBS.

653 To measure force transmission, Traction Force Microscopy (TFM) was performed
654 as previously described (Bangasser et al., 2017). Briefly, Nikon TiE and Ti2
655 epifluorescence microscopes were used to image fluorescent bead positions before and
656 after cell detachment via trypsin. A Zyla 5.5 sCMOS camera (Andor Technology,
657 Belfast, United Kingdom) and a 40x/0.95NA Ph2 lens with 1.5x intermediate zoom (60x
658 total magnification, 110 nm spatial sampling) was used. Cells were maintained at 37 °C

659 and 5% CO₂ for the duration of imaging using an Oko lab Bold Line top stage humidified
660 incubator (Okolab, Ottaviano, Italy). At each stage position, a phase contrast image of
661 the cell was acquired. Next, an image of fluorescent beads at the top surface of the gel
662 was captured using a 575/25 nm LED and eGFP/mCherry filter set with LED
663 fluorescence illumination from a SpectraX Light Engine (Lumencor, Beaverton, OR).
664 Media in dishes was carefully removed, cells were detached with 0.25% trypsin/EDTA
665 (Corning, Corning, NY), and fluorescence images of beads in the absence of cells were
666 acquired at saved stage positions.

667 Using a previously described method (Bangasser et al., 2017), the displacement
668 field was determined using particle image velocimetry (PIV) using the before and after
669 bead images. A window size of 80-pixels (8.8 μm) square was used in PIV and a final
670 lattice spacing of 20 pixels (2.2 μm) was achieved. Stress and displacement vectors
671 were obtained by solving the inverse Boussinesq problem in Fourier space (Butler et al.,
672 2002). By integrating the product of the stress and displacement vectors over the entire
673 image, substrate strain energy was determined as previously described (Bangasser et
674 al., 2017).

675

676 **Stochastic cell migration simulator**

677 The previously described (Bangasser et al., 2017; Klank et al., 2017) cell migration
678 simulator (CMS v1.0) was used to simulate cells migration dynamics in response to
679 changes in cell adhesion. The parameters used in the simulations are presented in
680 Table S3. The number of adhesive clutches (N_c) was adjusted to model the change in
681 adhesion observed between PDGF/Proneural and NRAS/Mesenchymal tumors. N_c of

682 2500 and 7500 clutches were used to simulate PDGF/Proneural and
683 NRAS/Mesenchymal tumor cells, respectively. Four hours of cell dynamics were
684 simulated and the first hour was excluded from analysis to allow the system to reach
685 steady state. Analysis was performed using a ten-minute sampling interval as previously
686 described (Bangasser et al., 2017).

687

688 **Brownian dynamics tumor simulator (BDTS)**

689 The Brownian dynamics tumor simulator was used as previously described with
690 modifications (Klank et al., 2018; Ray et al., 2018). In the present study, we extended
691 the BTDS to 3-dimensional tumors and incorporated immune cells' dynamics as shown
692 schematically in Figure 8A. Briefly, simulations started with 27 cancer cells, modeled as
693 rigid sphere with radius (r_{cancer}), placed in a 3x3x3 grid where the distance between
694 each cancer cell (center-center) is $3*r_{\text{cancer}}$. In simulation including immune response,
695 eight T cells, also modeled as rigid sphere with radius (r_{CTL}), were included, and each
696 was placed $1.5*r_{\text{cancer}}$ away from a randomly selected cancer cell. At each simulation
697 time step of 1 min, cancer and T cells are allowed to move randomly and grow as
698 spheres with a linear volumetric growth rate. Movement and growth are rejected if the
699 newly assigned space is already occupied by a like cell (i.e. no-overlap enforced
700 between cancer cells and between T cells). However, a cancer cell and T cell contact
701 occurs when a proposed cell movement put the distance between cell centers less than
702 or equal ($r_{\text{CTL}}+r_{\text{cancer}}$). The duration of the contact is ($1/k_{\text{dissoc}}$), in this case 10 minutes.
703 For every contact, both cancer cell and T cell take a "hit" that reduces their hit points
704 (HP) by one. Both cancer cell and T cell have limited HP and once HP is depleted

705 (equals 0), the cell dies or become exhausted. For NRAS simulations, T cells were
706 added to the tumor simulator and T cell-mediated killing was simulated. For PDGF
707 simulation, only cancer cells were simulated. Cancer cell motility was estimated from *ex*
708 *vivo* brain slice imaging of tumor cells (Figure 3C) and proliferation rate was estimated
709 from the *in vitro* proliferation of mouse primary tumor lines (Figure 7D). The rest of
710 parameters were estimated based on previous published work or used as an adjustable
711 parameter (see Table S5).

712

713 **Statistical analysis**

714 Fisher's exact test was used to compare the mouse and human transcriptomic clusters.
715 One-way analysis of variance was used to compare transcript levels. Analysis of
716 covariance (ANCOVA) was used to compare between the two regression lines in Figure
717 5C. Rank test, Kruskal-Wallis, one-way analysis of variance was used to compare
718 single cell behaviors and IHC quantifications. Where appropriate, a subsequent Dunn-
719 Sidak test for multiple comparisons was performed.

720

721 **DATA AND CODE AVAILABILITY:**

722 All data and codes are available on the Odde laboratory website (oddelab.umn.edu) or
723 on request from the corresponding author. Fastq files and the Cuffnorm output were
724 deposited at Gene Expression Omnibus (GSE161154).

725

726 **AUTHORS CONTRIBUTION:**

727 GAS, BLK, BRT, SSR, DAL and DJO contributed to study initiation, conception and
728 design.
729 GAS, CJL, BCB and DJO contributed to writing the manuscript
730 GAS, BCB and JMF contributed to developing mouse tumors
731 GAS, SKR and ALS contributed to the analysis of transcriptomic data.
732 GAS ran and analyzed the cell migration simulations
733 GAS and CJL contributed to the acquisition and analysis of glioma cell migration
734 GAS established tumor lines and performed traction force measurements
735 GAS, BCB and HBC contributed to imaging and analysis of histological sections
736 NG, PCR, DM and DJO contributed to the design and implementation of the Brownian
737 Dynamics Tumor Simulator
738 All authors contributed to the revisions of the manuscript

739

740 **CONFLICT OF INTEREST STATEMENTS:**

741 DAL is the co-founder and co-owner of several biotechnology companies including
742 NeoClone Biotechnologies, Inc., Discovery Genomics, Inc. (recently acquired by
743 immusoft, Inc.), B-MoGen Biotechnologies, Inc. (recently acquired by Bio-Techne
744 Corporation), and Luminary Therapeutics, Inc. DAL holds equity in, serves as a Senior
745 Scientific Advisor for and Board of Director member for Recombinetics, a genome
746 editing company. DAL consults for Genentech, Inc., which is funding some of his
747 research. The business of all these companies is unrelated to the contents of this
748 manuscript.

749

750 **ACKNOWLEDGMENTS:**

751

752 The authors would like to thank Drs. Chris Wilke and Clark C. Chen for helpful
753 discussion. This work was supported by National Institutes of Health grant U54
754 CA210190 to SSR, DAL and DJO and U54CA210180 to JNS. DAL acknowledges the
755 American Cancer Society Research Professor grant, the John and Jean Hedberg Brain
756 Tumor Fund, and the Children's Cancer Research Fund. The authors acknowledge the
757 Minnesota Supercomputing Institute (MSI) and University of Minnesota Genomic Center
758 at the University of Minnesota for providing resources that contributed to the research
759 results reported within this paper. We also acknowledge the Comparative Pathology,
760 Cancer Bioinformatics, and Cytogenomics Shared Resources at the Masonic Cancer
761 Center at the University of Minnesota for services.

977 **FIGURE LEGENDS:**

978 **Figure 1. *De novo* induced GBM mouse models using immune competent mice**
979 **recapitulate mesenchymal and proneural subtypes of human GBM.**

980 A) Schematic of mouse models. Plasmids encoding oncogenic drivers NRAS^{G12V} or
981 PDGF β in combination with SV40LgTA were injected into P1 FVB mice to induce
982 mesenchymal and proneural high grade gliomas, respectively. B) H&E and Ki67 IHC
983 staining of NRAS and PDGF tumor sections. Scale bar: 50 μ m. C) Unsupervised
984 hierarchical clustering of mRNA expression in induced mouse tumors and human IDH-
985 WT GBM-TCGA. Arrows indicate conserved genes present in both mouse and human
986 gene clusters as defined by systematic comparison of gene cluster membership
987 between datasets. D) Quantification of relative expression of mouse gene clusters
988 within the mouse dataset (top panel) and human GBM molecular subtypes (lower
989 panel). E,F) Relative expression of key mesenchymal and proneural genes within
990 mouse tumors (E) and human tumors (F). Solid and dashed lines represent mean and
991 median values, respectively. Error bar represents S.E.M. + p <0.05, * p <0.01, **
992 p <0.001, *** p <0.0001, **** p <0.00001.

993
994 **Figure 2. Simulations of cell migration as a function of subtype based on CD44-**
995 **mediated cellular adhesive clutches.**

996 A) Schematic of proneural (low CD44) and mesenchymal (medium CD44, i.e. optimal)
997 subtypes. B) Wind-rose plots of simulated cell trajectories on different stiffnesses (K_{sub} =
998 0.1, 1, 10 pN/nm). C) Simulated cell migration random motility coefficients show higher
999 migration with increased (optimal) adhesion across a range of substrate stiffnesses. D)
1000 Cell summed traction force exhibits higher traction forces with increased (optimal)
1001 adhesion across all stiffnesses. E, F) Cell spread area and aspect ratio increase with
1002 increased adhesion on substrate stiffnesses of 0.1 and 1 pN/nm. Error bars are S.E.M.

1003
1004 **Figure 3. NRAS/Mesenchymal cells migrate faster, are more spread, and are more**
1005 **polarized than PDGF/Proneural cells in *ex vivo* tumor-bearing brain tissue.**

1006 A) Representative *ex vivo* fluorescent montage of GFP-tagged tumor cells (green) and
1007 blood vessels staining using isolectin B4 (magenta). B) Wind rose plots of
1008 NRAS/Mesenchymal and PDGF/Proneural migrating tumor cell migration trajectories
1009 (N=46). C) NRAS/Mesenchymal cancer cell motility is faster than for PDGF/proneural
1010 cancer cells. D&E) NRAS/Mesenchymal cancer cells are more spread and polarized
1011 than PDGF/Proneural cells as evidenced by larger spread area and aspect ratio. Solid
1012 and dashed lines represent mean and median, respectively. N represents the number of
1013 individual cells tracked from 3 mice from each cohort. Error bars are S.E.M. +p <0.05, *
1014 p <0.01, ** p <0.001, *** p <0.0001, **** p <0.00001.

1015
1016 **Figure 4. Cancer cell migration is subtype specific and independent of the tumor**
1017 **microenvironment and species.**

1018 A) Six representative images of primary isolated cells from each of the two mouse tumor
1019 subtypes (3 NRAS and 3 PDGF). GFP-tagged tumor cells (green) and blood vessels
1020 staining using isolectin B4 (magenta). B) NRAS/Mesenchymal primary isolated tumor
1021 cancer cells migrate faster than PDGF/Proneural primary isolated cancer cells in normal

1022 mouse brain tissue as measured by random motility coefficient, see Video S2. C&D)
1023 Quantification of cell spread area and cell aspect ratio showing that
1024 NRAS/Mesenchymal cancer cells are more spread (C) and tend to be somewhat more
1025 polarized (D), $p=0.075$, than PDGF/Proneural cancer cells in healthy brain slices. E) Six
1026 representative images of proneural and mesenchymal PDX lines cells in healthy mouse
1027 brain tissue. Labeled tumor cells using DiO membrane dye (green) and blood vessel
1028 staining using isolectin B4 (magenta). F) Mesenchymal PDX cells migrate faster than
1029 proneural PDX cells in normal mouse brain tissue as measured by random motility
1030 coefficient, see Video S3. G&H) Quantification of cell spread area and cell aspect ratio
1031 showing that mesenchymal PDX cells are more spread (G) and are more polarized (H)
1032 than proneural PDX cells in healthy brain slices. Solid and dashed lines represent mean
1033 and median values respectively. N represents the number of individual cells tracked
1034 from 3 mouse primary cell lines from each cohort. Error bars are S.E.M. +p <0.05, * p
1035 <0.01, ** p<0.001, *** p<0.0001, **** p<0.00001.

1036
1037 **Figure 5. NRAS/Mesenchymal cancer cells generate larger traction forces *in vitro***
1038 **on 2D hydrogels and *ex vivo* in brain slices than PDGF/Proneural cancer cells.** A)
1039 Representative phase contrast images and traction force magnitude heatmaps on type I
1040 collagen-coated polyacrylamide hydrogels across different substrate stiffnesses. B)
1041 NRAS/Mesenchymal cancer cells (red) generate higher traction forces as measured by
1042 total strain energy relative to PDGF/Proneural (blue) cancer cells. Measurement noise is
1043 presented (grey) across all stiffnesses. C) Similar to mouse brain slices,
1044 NRAS/Mesenchymal cancer cells (red) cultured on collagen-coated polyacrylamide
1045 hydrogels have larger spread area than PDGF cancer cells (blue). D &E) Tissue
1046 deformation visualized using temporal-color coding using 2 hours time-lapse and 15
1047 minutes time interval. Mesenchymal PDX cells generate larger deformations of mouse
1048 brain capillaries (E) than proneural PDX cells shown in (D). Scale bar = 20 μm , and
1049 inset scale bar = 10 μm . Solid and dashed lines represent mean and median values,
1050 respectively. N represents individual cell measurements from three mouse primary cell
1051 lines from each cohort with a minimum of two technical replicates. Error bars are S.E.M.
1052 +p <0.05, * p <0.01, ** p<0.001, *** p<0.0001, **** p<0.00001.

1053
1054 **Figure 6. NRAS/Mesenchymal mice live longer than PDGF/Proneural mice.** A)
1055 Kaplan-Meier plot of animal survival for NRAS/Mesenchymal and PDGF/Proneural
1056 tumor-bearing mice shows extended survival of the NRAS/Mesenchymal cohort. Log
1057 rank Mantel-Cox test $p<0.00001$. B) Bioluminescence imaging (BLI) of
1058 NRAS/Mesenchymal mice shows slower growing tumors relative to PDGF/Proneural
1059 mice. C) Quantification of BLI integrated intensity for the two cohorts. Normalized BLI
1060 intensity for all data points and linear fits for each cohort. PDGF/Proneural
1061 slope= 0.127 ± 0.01191 and NRAS/Mesenchymal slope= 0.0716 ± 0.00343 , D) Normalized
1062 cell count of primary isolated mouse tumor cells showing no significant difference in
1063 proliferation rate *in vitro* using neurosphere culture. Solid and dashed lines represent
1064 mean and median values, respectively. Error bars are S.E.M. +p <0.05, * p <0.01, **
1065 p<0.001, *** p<0.0001, **** p<0.00001.

1066

1067 **Figure 7. NRAS/Mesenchymal tumors are relatively immunologically “hot” and**
1068 **PDGF/Proneural tumors are immunologically “cold,” consistent with human GBM**
1069 **subtypes.** A, B) Clustering analysis of immune activators and suppressors previously
1070 reported in human GBM (Doucette *et al.*, 2013). Similar to mesenchymal GBM,
1071 NRAS/Mesenchymal tumors have elevated immune activator and suppressor
1072 expression relative to normal brain tissue and PDGF/Proneural tumors. C) Expression
1073 of immune cell surface marker genes in mouse (top) and human (bottom) tumors shows
1074 elevated expression in NRAS/Mesenchymal tumors and human mesenchymal GBM
1075 tumors relative to PDGF/Proneural and human proneural GBM tumors. D)
1076 Immunohistochemistry (IHC) confirms elevated immune cell infiltration in NRAS tumors
1077 and associated elevation of immune-mediated killing of tumor cells. E,F,G,H)
1078 Quantification of IHC images using a k-means clustering algorithm. Solid and dashed
1079 lines represent mean and median values, respectively. Error bars are S.E.M. +p <0.05 *
1080 p <0.01, ** p<0.001, *** p<0.0001, **** p<0.00001.

1081
1082 **Figure 8. Brownian dynamics tumor simulator (BDTS) of 3D NRAS/Mesenchymal**
1083 **and PDGF/Proneural tumors.** A) Schematic showing a diagram of the model. B)
1084 Simulator output at day 0 and day 16 for PDGF and NRAS simulations. In NRAS
1085 simulations, dead cancer cells are larger grey spheres and T cells are smaller black
1086 spheres, see Video S4. C) Cancer cell count over time showing the difference in tumor
1087 growth in the presence of T cells with simulated PDGF/Proneural tumors growing faster
1088 than NRAS/mesenchymal tumors. D) Cartoon summary of the main findings depicting
1089 the relationship between molecular subtypes, cellular adhesion, cell migration, and
1090 immune response.

1091

1092 SUPPLEMENTARY FIGURE AND TABLES LEGENDS:

1093 **Figure S1. Unsupervised clustering of mouse tumor and healthy brain tissue**
1094 **transcriptomic profiles and pathway enrichment analysis.** A) Heatmap showing
1095 expression profile of NRAS and PDGF tumors and healthy mouse brain tissues.
1096 Heatmap shows existence of three gene clusters: Tumor-specific cluster, normal brain
1097 tissue specific cluster and NRAS tumor-specific cluster. B,C&D) Gene ontology analysis
1098 of gene clusters was performed using EnrichR.

1099
1100 **Figure S2. Clustering analysis of mouse and human tumors using gene**
1101 **signatures associated with classical, mesenchymal, and proneural subtypes.** A)
1102 Heatmap shows the clustering of human GBM samples using subtype-specific gene
1103 signatures. B) Heatmap shows the clustering of mouse tumors using subtype-specific
1104 gene signatures. C&D) Quantification of subtype gene signatures within human GBM
1105 subtypes and NRAS and PDGF mouse tumors. Solid and dashed lines represent mean
1106 and median values respectively. Error bars are S.E.M. +p <0.05, * p <0.01, ** p<0.001,
1107 *** p<0.0001, **** p<0.00001.

1108
1109 **Figure S3. Differential expression analysis of cell migration genes.** Volcano plot
1110 depicting $-\log_{10}(\text{adj } p \text{ value})$ calculated using FDR adjusted Student's t test versus
1111 $\log_2(\text{average FC})$ for individual genes in A) mouse tumors and B) human TCGA-GBM

1112
1113 **Figure S4. Quantification of single cell migration and cell morphology.** A, B, & C)
1114 *Ex vivo* migration and morphology data from each individual animal. D, E, & F)
1115 Migration and morphology data for each individual mouse primary tumor line in mouse
1116 organotypic brain slice. G, H, & I) Migration and morphology data for each individual
1117 PDX line in mouse organotypic brain slice.

1118
1119 **Figure S5. BL image sequences showing tumor regression in some rare cases.** All
1120 three surviving mice in NRAS cohort showed tumor regression.

1121
1122 **Figure S6. Expression of immune checkpoint genes within mouse tumors.**
1123 Expression of immune checkpoint genes were upregulated in NRAS tumors relative to
1124 PDGF tumors (B) similar to human mesenchymal and proneural (A).

1125
1126 **Video S1.** Related to Figure 3. GFP-positive NRAS and PDGF tumor cells migrating in
1127 tumor bearing brain slices over 10 hours. Green shows tumor cells and magenta shows
1128 blood vasculature. Scale bar: 100 μm .

1129
1130 **Video S2.** Related to Figure 4A. GFP-positive NRAS and PDGF primary tumor cells
1131 migrating in mouse organotypic brain slice over 16 hours. Green shows tumor cells and
1132 magenta shows blood vasculature. Scale bar: 100 μm .

1133
1134 **Video S3.** Related to Figure 4D. Proneural and mesenchymal human PDX GBM cells
1135 migrating in mouse organotypic brain slice over 16 hours. Green shows tumor cells

1136 stained using green DiO membrane dye and magenta shows blood vasculature. Scale
1137 bar: 100 μ m.

1149

1150 **Table S4.** Related to Figure 4. Characteristics of patient-derived xenograft (PDX) lines
1151 used in this study.

1152

1153 **Table S5.** Related to Figure 8. List of Brownian dynamics tumor simulator parameter
1154 values.

1155

1156 **Table S6.** List of antibodies and reagents used in IHC staining.

1157

1158 **Table S3:** Cell migration simulator parameter values

Symbol	Parameter	Value
N_m	Total number of motors	10,000
N_c	Total number of clutches	250; 750
A_{tot}	Total possible actin protrusion length	100 μm
v_p^*	Maximum actin polymerization velocity	200 nm/s
k_{mod}^*	Maximum module birth rate	1 s^{-1}
k_{cap}	Module capping rate	0.001 s^{-1}
l_{in}	Initial module length	5 μm
l_{min}	Minimum module length	0.1 μm
K_{cell}	Cell spring constant	10,000 pN/nm
$n_{c,cell}$	Number of cell body clutches	10;
n_m^*	Maximum number of module motors	$0.1 * N_c$
F_m	Motor stall force	2 pN
v_m^*	Unloaded motor velocity	120 nm/s
n_c^*	Maximum number of module clutches	75; 750
k_{on}	Clutch on-rate	1 s^{-1}
k_{off}^*	Clutch unloaded off-rate	0.1 s^{-1}
K_c	Clutch spring constant	0.8 pN/nm
F_b	Characteristic clutch rupture force	2 pN
K_s	Substrate spring constant	Variable

1160 **Table S4:** Characteristics of patient-derived xenograft (PDX) lines used in this study

GBM	Xenograft start	Sex	Molecular subtype (RNAseq)
GBM16	2002	F	mesenchymal
GBM39	2003	M	mesenchymal
GBM44	2003	F	mesenchymal
GBM64	2006	F	proneural
GBM80	2007	M	proneural
GBM85	2008	M	proneural

1161

1162 **Table S5: Brownian dynamics tumor simulator parameters values**

Parameter Name	Parameter	Value	Units	Reference
Cancer cell radius	r_{cancer}	10	μm	This study
T cell radius	r_{CTL}	3	μm	This study
Cancer cell motility	D_{cancer}	7.8; 42	$\mu\text{m}^2/\text{h}$	This study
T cell motility	D_{CTL}	300	$\mu\text{m}^2/\text{hr}$	(Boissonnas et al., 2007; Halle et al., 2016)
Cancer cell proliferation	ρ_{cancer}	0.5	1/d	This study
T cell proliferation	ρ_{CTL}	1	1/d	(Riggs et al., 2008)
Contact duration	$1/k_{\text{dissoc}}$	10	min	(Halle et al., 2016, 2017)
Cancer cell HP*	$\text{HP}_{\text{cancer}}$	1	contacts	(Halle et al., 2016)
T cell HP*	HP_{CTL}	20	contacts	Unknown, adjustable

1184 **Table S6:** IHC antibodies and reagents used in Figure 1A and Figure 7D

IHC	Antibody	Antigen retrieval	Blocking	Detection
Ki67	CRM325	High pH EDTA	Dako protein block	Dako rabbit envision
CD3a	A0452	High pH EDTA	Dako protein block	Biocare rat detection
IBA-1	AB107159	Low pH citrate	Dako protein block	Biocare goat detection
Cleaved Caspase-3	Asp175	High pH EDTA	Dako protein block	Dako rabbit envision
Granzyme B	D6E9W	Low pH citrate	Vectastain, goat serum	Vectastain ABC-HRP
