28   **Abstract**

29

30   Nirmatrelvir, an oral antiviral targeting the 3CL protease of SARS-CoV-2, has been

31   demonstrated to be clinically useful in reducing hospitalization or death due to COVID-19[1,2].

32   However, as SARS-CoV-2 has evolved to become resistant to other therapeutic modalities[3-9],

33   there is a concern that the same could occur for nirmatrelvir. Here, we have examined this

34   possibility by *in vitro* passaging of SARS-CoV-2 in increasing concentrations of nirmatrelvir

35   using two independent approaches, including one on a large scale in 480 wells. Indeed, highly

36   resistant viruses emerged from both, and their sequences revealed a multitude of 3CL protease

37   mutations. In the experiment done at scale, 53 independent viral lineages were selected with

38   mutations observed at 23 different residues of the enzyme. Yet, several common mutational

39   pathways to nirmatrelvir resistance were preferred, with a majority of the viruses descending

40   from T21I, P252L, or T304I as precursor mutations. Construction and analysis of 13

41   recombinant SARS-CoV-2 clones, each containing a unique mutation or a combination of

42   mutations showed that the above precursor mutations only mediated low-level resistance,

43   whereas greater resistance required accumulation of additional mutations. E166V mutation

44   conferred the strongest resistance (~300-fold), but this mutation resulted in a loss of viral

45   replicative fitness that was restored by compensatory changes such as L50F and T21I. Structural

46   explanations are discussed for some of the mutations that are proximal to the drug-binding site,

47   as well as cross-resistance or lack thereof to ensitrelvir, another clinically important 3CL

48   protease inhibitor. Our findings indicate that SARS-CoV-2 resistance to nirmatrelvir does readily

49   arise via multiple pathways *in vitro*, and the specific mutations observed herein form a strong

50   foundation from which to study the mechanism of resistance in detail and to shed light on the

51   design of next generation protease inhibitors.

52

**Main text**

The COVID-19 (coronavirus disease 2019) pandemic has continued to affect the global populace. The rapid development and deployment of effective vaccines as well as monoclonal antibody therapeutics beginning in late 2020 have helped to greatly curtail its impacts[10-16]. Yet, the etiologic agent, SARS-CoV-2 (severe acute respiratory syndrome coronavirus 2), has continuously evolved to develop resistance to antibody-mediated neutralization[4-8]. In particular, several of the recent Omicron subvariants exhibit such strong antibody resistance that a majority of current antibodies, both vaccine-elicited polyclonal sera and monoclonal therapeutics, have lost efficacy[4,5,8], as manifested by increasing breakthrough infections in convalescing and/or vaccinated individuals[3].

Fortunately, treatment options remain. In the United States, three antivirals have received emergency use authorization for COVID-19 treatment: remdesivir[17,18], molnupiravir[19-21], and nirmatrelvir[1,2] (also known as PF-07321332, used in combination with ritonavir and marketed as PAXLOVID™). The first two target the RNA-dependent RNA polymerase (RdRp), and the latter targets the 3CL protease (3CL$^{pro}$; also known as main protease (M$^{pro}$) and nonstructural protein 5 (nsp5)). Both enzymes are essential for the viral life cycle and relatively conserved among coronaviruses[22,23]. Remdesivir is administered intravenously and has a reported relative risk reduction of 87%[18], whereas molnupiravir and nirmatrelvir are administered orally and have reported clinical efficacies of 31%[20] and 89%[1], respectively, in lowering hospitalization or death. As the use of these antivirals increases, there is a concern that drug resistance may arise, particularly if given as monotherapies. For remdesivir, *in vitro* and *in vivo* studies have revealed mutations associated with resistance[9,24,25], and resistance to molnupiravir or nirmatrelvir is now under active investigation. Here, we report that there are multiple routes by which SARS-CoV-2 can gain resistance to nirmatrelvir *in vitro*.

**Nirmatrelvir resistance in Vero E6 cells**

To select for resistance to nirmatrelvir, SARS-CoV-2 (USA-WA1/2020 strain) was passaged in the presence of increasing concentrations of the drug (see **Methods** for details). We conducted this initial experiment in triplicate, using Vero E6 cells as they have been one of the standard cell lines used in COVID-19 research. After 30 passages, each of the three lineages demonstrated a

84   high level of resistance, with $IC_{50}$ values increasing 33 to 50-fold relative to that of the original

85   virus (**Figs. 1a-d**). Examination of earlier viral passages confirmed a stepwise increase in

86   nirmatrelvir resistance with successive passaging (**Figs. 1b-d**), without any evidence of

87   resistance to remdesivir (**Fig. 1e**). The resistant viruses selected by passaging maintained their

88   replicative fitness *in vitro*, with similar growth kinetics as those passaged without nirmatrelvir

89   (**Extended Data Fig. 1**).

90

91   We then sequenced the 3CL$^{pro}$ gene from the three viral lineages collected every three passages

92   to investigate which mutations may confer resistance (**Fig. 1f**). We found that the three lineages

93   harbored unique mutations, with only one mutation, at most, overlapping between the different

94   lineages (T21I in lineages A and B, L50F in lineages B and C, and T304I in lineages A and C).

95   The observed mutations occurred in a stepwise manner, mirroring the increases in drug

96   resistance (**Fig. 1f**), and a number of them, but not all, were situated near the nirmatrelvir-

97   binding site (**Fig. 1g**). These results suggested that SARS-CoV-2 could readily develop

98   nirmatrelvir resistance using several mutational pathways.

99

**Nirmatrelvir resistance in Huh7-ACE2 cells at scale**

101   We therefore set out to conduct another passaging experiment to select for nirmatrelvir resistance,

102   but this time at scale to better capture the multitude of solutions that SARS-CoV-2 could adopt

103   when put under drug pressure. For these later studies, we utilized Huh7-ACE2 cells to examine if

104   differences would arise in human cells, and because Vero E6 cells express high levels of P-

105   glycoprotein, an efflux transporter that limits the intracellular accumulation of nirmatrelvir[26]. We

106   passaged SARS-CoV-2-mNeonGreen (USA-WA1/2020 background with ORF7 replaced with

107   mNeonGreen[27]) independently in 480 wells for 16 passages, with increasing concentrations of

108   nirmatrelvir over time, and viruses from every fourth passage were subjected to next-generation

109   sequencing (NGS) (**Fig. 2a** and see **Methods** for details). After 16 passages, varying degrees of

110   nirmatrelvir resistance were observed as exemplified by the three viruses shown (**Fig. 2b**).

111   Sequencing of the 3CL$^{pro}$ in all wells that retained mNeonGreen signal identified 53 mutant

112   populations (**Fig. 2c**). Mutations were observed across 23 residues within the enzyme, both

113   proximal and distal to the catalytic pocket that nirmatrelvir occupies (**Fig. 2d**). While there was

114   widespread diversity among the passaged populations, seven mutations appeared ten or more

115    times: T21I, L50F, S144A, E166V, A173V, P252L, and T304I. Mutations were only rarely

116    observed across 3CL$^{pro}$ cut sites within the polyproteins, except those at the termini of 3CL$^{pro}$

117    itself (T304I at the nsp5/6 site), suggesting that substrate cleavage site alterations are not majorly

118    responsible for the nirmatrelvir resistance (**Extended Data Fig. 2**).

119

120    Sequencing of the same wells at earlier passages revealed less diversity in 3CL$^{pro}$, with 11, 16,

121    and 22 residues mutated within viruses from passages 4, 8, and 12, respectively (**Supplemental**

122    **Table 1**). As a standard phylogenetic analysis showed a rather complex stepwise order of

123    acquisition of mutations for each passaged lineage (**Extended Data Fig. 3**), we more carefully

124    analyzed the order in which mutations arose across the various lineages (see **Methods** and

125    **Supplemental Table 1** for details) and generated a pathway network delineating the most

126    common routes that SARS-CoV-2 took *in vitro* to develop nirmatrelvir resistance (**Fig. 3a**). The

127    majority of these viral lineages descended initially from T21I, P252L, and T304I, suggesting that

128    these mutations may serve as "founder" or "precursor" mutations when the drug concentrations

129    are relatively low. Additional mutations then occurred, probably to increase the level of

130    resistance as the drug concentrations were increased and/or to compensate for reduced viral

131    fitness. These findings indicated that although there are multiple solutions for SARS-CoV-2 to

132    resist nirmatrelvir, several common mutational pathways are favored.

133

134    **Mutations conferring nirmatrelvir resistance**

135    To further investigate which mutations were responsible for nirmatrelvir resistance, we

136    proceeded to generate recombinant SARS-CoV-2 clones, each containing a unique mutation or a

137    combination of mutations. To construct the 15 mutant viruses from the first passage experiment

138    (**Fig. 1f**) and the 22 mutant viruses from the second passage experiment (**Fig. 3a**) would be

139    beyond the scope of the current study. We therefore decided to focus on the seven most common

140    single point mutants from the large passaging study, as well as five double mutants and one triple

141    mutant (**Extended Data Fig. 4**). All viruses grew similarly to wild type (WT) in the absence of

142    drug, except for S144A, E166V, and T21I + S144A, which were significantly impaired in their

143    growth kinetics (**Fig. 3b**). However, both T21I + E166V and L50F + E166V replicated well with

144    kinetics similar to WT, suggesting that T21I and L50F each compensated for the fitness loss of

145    E166V. Of the individual mutants tested against nirmatrelvir, E166V was most resistant (nearly

5

146   300-fold), with T21I, P252L, and T304I having moderate resistance (~6-10-fold), whereas L50F,

147   S144A, and A173V having minimal resistance (~3-fold or less) (**Figs. 4a, 4b and Extended**

148   **Data Fig. 5**). Combination of T21I with S144A or E166V resulted in a virus that was

149   substantially resistant to nirmatrelvir (~29 or 60-fold, respectively). Notably, addition of L50F to

150   E166V led to a virus that remained highly resistant (130-fold) but with WT replicative kinetics

151   (**Fig. 3b**).

152

153   We next tested this panel of viruses against ensitrelvir[28] (also known as S-217622), another 3CL

154   protease inhibitor that has demonstrated clinical efficacy[29], for cross-resistance together with

155   remdesivir as a control. Only S144A, E166V, and T21I + S144A showed substantial (~7 to 25-

156   fold) cross-resistance to ensitrelvir (**Fig. 4b and Extended Data Figs. 5, 6**). As expected, none

157   of these mutations conferred resistance to remdesivir. We additionally tested the passage 30

158   viruses resulting from the initial selection experiment in Vero E6 cells (**Fig. 1**) against these two

159   inhibitors. Again, all three lineages were as susceptible to remdesivir as WT, and only lineage C

160   (L50F + F140L + L167F + T304I) showed cross-resistance to ensitrelvir (~25-fold) (**Extended**

161   **Data Fig. 7**). This may be due to F140L, since L50F and T304I did not demonstrate ensitrelvir

162   resistance (**Fig. 4b**) and L167 does not contact ensitrelvir (see below). Together, these results

163   suggest that some mutations, such as E166V, can confer a high degree of nirmatrelvir resistance

164   alone, while others, such as T21I, P252L, and T304I, confer only moderate nirmatrelvir

165   resistance individually but can act synergistically with other mutations to confer higher levels of

166   resistance. The degree of cross-resistance to ensitrelvir was variable among the tested mutant

167   viruses probably due to the differences in binding of these drugs to the catalytic pocket of 3CL$^{pro}$

168   (**Fig. 4c**). Nevertheless, it is clear that selection for nirmatrelvir resistance can yield mutations

169   that confer cross-resistance to other inhibitors of clinical interest as well.

170

171   To begin to understand the mechanisms underlying the resistance conferred by these mutations,

172   we considered their structural context. Nirmatrelvir and ensitrelvir both bind within the catalytic

173   pocket, but in differing modes, which may result in the differences observed in the inhibition

174   profiles of the mutants (**Figs. 4b, 4c**). E166 directly interacts with the lactam ring of nirmatrelvir

175   via hydrogen binding, and the valine substitution at this position may abrogate some of these

176   interactions to result in the strong drug resistance observed (**Fig. 4d**). E166 is also able to form

6

177    hydrogen bonds with the first residue (S1) of the neighboring protomer and may be involved in
178    dimerization, which plays an important role in maintaining the viral protease activity[30]. The
179    disruption of the hydrogen-bonding interactions (**Fig. 4d**) may explain the reduced fitness of the
180    E166V mutant (**Fig. 3b**). The side chain of S144 forms a hydrogen bond with the main chain of
181    L141 to stabilize the S1 subsite of the catalytic pocket, so the S144A mutation may disorder this
182    region and hamper the binding of both nirmatrelvir and ensitrelvir (**Fig. 4e**), although it is not
183    clear why this requires the T21I mutation in conjunction. L167 participates in the formation of
184    the S4 subsite, and the L167F mutation may cause a steric clash with nirmatrelvir (**Fig. 4f**).
185    However, as ensitrelvir does not extend into the S4 subsite, this mutation may not be responsible
186    for the cross-resistance observed in lineage C (**Extended Data Fig. 7**). As F140 interacts by π-π
187    stacking interactions with H163, which directly interacts with both nirmatrelvir and ensitrelvir,
188    the F140L mutation may abrogate this interaction, resulting in resistance (**Figs. 4c, 4d and**
189    **Extended Data Fig. 7**). For a number of these mutations, however, it is not immediately
190    apparent how they confer drug resistance given that they are distant from the catalytic pocket
191    where the drugs bind (**Extended Data Fig. 4**).

192

193    Finally, we compared the mutations identified in this study to clinical SARS-CoV-2 sequences
194    reported to GISAID[31]. Nearly all of the mutations we have identified were observed among the
195    viruses circulating in the population, albeit at low frequencies (**Extended Data Fig. 8a**).
196    Comparing the frequencies of these mutations in periods before and after the authorization of the
197    combination of nirmatrelvir and ritonavir (PAXLOVID™) did not show an appreciable increase
198    in the observed mutations (**Extended Data Fig. 8b**).

199

200    **Discussion**
201    As antibody-based interventions for SARS-CoV-2 face increasing resistance by the emergence
202    of variants of concern, antivirals with alternative modes of action have increased in importance.
203    Nirmatrelvir, as an oral antiviral targeting 3CL[pro], is a therapeutic that has shown high efficacy in
204    lowering severe disease and hospitalization in infected persons who are at high risk and not
205    vaccinated[1,2]. Indeed, it is the most commonly used antiviral drug to treat COVID-19 today[32].
206    Given the adaptations that the virus has already exhibited to other modes of treatment[3-9], it is
207    clinically important to understand the mechanisms by which nirmatrelvir resistance can occur.

7

208   The results presented herein demonstrate that *in vitro* high-level resistance to nirmatrelvir can be
209   readily achieved by SARS-CoV-2, and that this can occur in a multitude of ways. This major
210   finding was somewhat anticipated because of our prior report on the extensive plasticity of the
211   3CL$^{pro}$ as discovered by deep mutational scanning[33].

212

213   In both Vero E6 cells (**Fig. 1**) and Huh7-ACE2 cells (**Fig. 2**), multiple lineages with non-
214   overlapping mutations evolved under increasing drug pressure, consistent with what has been
215   seen in similar small-scale studies[24,25,34,35]. Conducting selection at scale, however, revealed that
216   there are multiple mutational pathways to nirmatrelvir resistance but with several common
217   trajectories preferred (**Figs. 2c, 3a**). A majority of lineages descended from viruses that acquired
218   T21I, P252L, or T304I as an initial mutation. Recombinant SARS-CoV-2 constructed to contain
219   each of these point mutants were moderately resistant (**Figs. 4a, 4b**), suggesting that each of
220   these precursor mutations may have allowed the virus to tolerate low concentrations of
221   nirmatrelvir but required additional mutations as the drug pressure was increased. Notably, all
222   three of these mutations are rather distal from the substrate binding pocket within which
223   nirmatrelvir binds (**Fig. 2d**), and their mechanism for resistance is not evident without additional
224   studies. We note, however, that T304 corresponds to the P3 site on the nsp5/6 cleavage substrate
225   for 3CL$^{pro}$ of both SARS-CoV and SARS-CoV-2 (**Extended Data Fig. 2**). Although the P3 site
226   is exposed to solvent and thus not considered to confer stringent substrate specificity, it has been
227   shown that a suitable functional group (such as the side chain of isoleucine) at the P3 site can
228   assist in increasing inhibitor/substrate potency and selectivity for 3CL$^{pro}$s[36-38]. Therefore, it is
229   possible that T304I could facilitate the binding of the nsp5/6 cleavage site or promote the
230   autocleavage process.

231

232   Analyses with isogenic mutants also revealed that several mutations are responsible for the
233   observed nirmatrelvir resistance, with the E166V mutation conferring the most resistance (~300-
234   fold) (**Fig. 4b**), as is being reported elsewhere[33,35]. This mutation, as well, conferred a degree of
235   cross-resistance to ensitrelvir, another clinically relevant 3CL$^{pro}$ inhibitor[28,29]. The mechanism of
236   resistance of E166V is explainable since it resides in the catalytic pocket, and the valine
237   substitution disrupts its hydrogen bonding to the lactam ring of nirmatrelvir (**Fig. 4d**). However,
238   this mutation lowered the replicative fitness of the virus in vitro (**Fig. 3b**), perhaps because of a

239    loss of interaction with the first residue of the neighboring protomer in dimerization (**Fig. 4d**)[30].

240    Importantly, replicative fitness was restored when T21I or L50F was added (**Fig. 3b**), without a

241    significant impact on drug resistance (**Fig. 4b**). How these two mutations compensate for the

242    fitness loss of E166V remains unknown.

243

244    We have also found that a number of additional mutations could confer resistance to nirmatrelvir

245    *in vitro*. T21I + S144A mediated not only significant resistance to nirmatrelvir but also cross-

246    resistance to ensitrelvir (**Fig. 4b**), but this virus exhibited slower growth kinetics (**Fig. 3b**).

247    Likewise, we inferred that both L167F and F140L were likely mediating drug resistance in the

248    C-P30 lineage of the first *in vitro* passaging experiment (**Fig. 1f**) as discussed above along with

249    possible structural explanations. It is clear, nevertheless, that we have only studied a limited

250    number of the mutational pathways that SARS-CoV-2 took to evade nirmatrelvir. Furthermore,

251    many of the mutations revealed by our study are without a straightforward structural explanation

252    at this time. It will require extensive virological, biochemical, and structural studies to delineate

253    which mutations confer resistance and how, as well as to understand how certain mutations play

254    compensatory roles. A better understanding of the mechanisms of nirmatrelvir resistance could

255    provide insight into the development of the next generation of 3CL$^{pro}$ inhibitors.

256

257    Nirmatrelvir has been used to treat COVID-19 for only 6 months or less in most countries.

258    SARS-CoV-2 resistance to this drug in patients has yet to be reported, and we see no appreciable

259    difference in frequencies of the 3CL$^{Pro}$ mutations that we have uncovered in periods before and

260    after the emergency use authorization (**Extended Data Fig. 8**). Perhaps the lack of nirmatrelvir

261    resistance in patients to date is due to the high drug concentrations achieved with the prescribed

262    regimen, making it difficult for the virus to accumulate mutations in a stepwise manner.  In

263    addition, the drug is administered while the immune system is also actively eliminating the virus,

264    including any resistant forms that may have emerged. Therefore, it makes sense to focus our

265    surveillance effort on immunocompromised individuals on nirmatrelvir treatment for the

266    appearance of drug-resistant virus. Past experience with other viral infections tells us that if drug

267    resistance could be selected *in vitro*, it surely will occur *in vivo*. Although current COVID-19

268    therapies have been largely administered as monotherapies, it is likely that future treatment will

269    necessitate the use of a combination of drugs to minimize the likelihood of SARS-CoV-2 escape.

9

270

271    **Figure Legends**

272

273    **Fig. 1. Identification of nirmatrelvir resistance in Vero E6 cells. a,** Changes in $IC_{50}$ during

274    passaging of SARS-CoV-2 with nirmatrelvir. Vero E6 cells were infected in triplicate with

275    SARS-CoV-2 (USA-WA1/2020) and passaged to fresh cells every 3 days for 30 passages. See

276    Methods for additional details. **b-d,** Validation of nirmatrelvir resistance from the indicated

277    passage from each of the three lineages, A, B, and C, respectively. **e,** Inhibition of passage 30

278    viruses from each lineage by remdesivir. **f,** Mutations in 3CL$^{pro}$ found in the indicated passages

279    from each lineage. Dots indicate wild-type at that residue. **g,** Residues mutated in passaging in

280    Vero E6 cells overlaid onto the 3CL$^{pro}$ structure with nirmatrelvir bound. The Cα of each residue

281    that was mutated is denoted with a red sphere. The 3CL$^{pro}$-nirmatrelvir complex was downloaded

282    from PDB under accession code 7VH8. Error bars denote mean ± s.e.m of four technical

283    replicates in **a-e**.

284

285    **Fig. 2. Identification of nirmatrelvir resistance at scale in Huh7-ACE2 cells. a,** Passaging

286    scheme. 480 wells were infected with SARS-CoV-2-mNeonGreen and passaged to fresh Huh7-

287    ACE2 cells every 3-4 days, with the concentration of drug doubled every two passages. **b,**

288    Validation of nirmatrelvir resistance of three wells from passage 16. Representative curves from

289    a single experiment from two biologically independent experiments are shown. Error bars denote

290    mean ± s.e.m of three technical replicates. **c,** Mutations in 3CL$^{pro}$ found in passage 16 from 53

291    wells. Dots indicate wild-type at that residue. **d,** Residues mutated in passaging in Huh7-ACE2

292    cells overlaid onto the 3CL$^{pro}$ structure with nirmatrelvir bound. The Cα of each residue that was

293    mutated is denoted with a red sphere. The 3CL$^{pro}$-nirmatrelvir complex was downloaded from

294    PDB under accession code 7VH8.

295

296    **Fig. 3. Pathways for SARS-CoV-2 resistance to nirmatrelvir. a,** Observed pathways for

297    nirmatrelvir resistance in Huh7-ACE2 cells. The most commonly observed mutations in passage

298    16 were used to build these pathways (see **Methods** for additional details). Nodes are colored

299    from dark to light, with founder mutations colored darker. Percentages indicate the frequency by

300    which the child nodes derive from the immediate parental node. Descendent arrows that do not

301    sum to 100% indicate that a proportion did not advance beyond the indicated mutations in the

11

302    experiment. **b,** Growth assay with recombinant live SARS-CoV-2 carrying single and
303    combination 3CL[pro] mutations. Huh7-ACE2 cells were infected with 0.01 MOI of virus and
304    luminescence was quantified at the indicated time points. S144A, E166V, and T21I + S144A are
305    statistically significant from WT at 48 h (two-way ANOVA with Geisser-Greenhouse correction
306    followed by Dunnett's multiple comparisons test; P=0.0039, P=0.0006, P=0.0006, respectively).
307    Representative curves from a single experiment from two biologically independent experiments
308    are shown. Error bars denote mean $\pm$ s.e.m of three technical replicates.

309

310    **Fig. 4. Validation of identified mutations in isogenic recombinant SARS-CoV-2. a,**
311    Individual inhibition curves of recombinant live SARS-CoV-2 carrying single and combination
312    3CL[pro] mutations by nirmatrelvir. Representative curves from a single experiment from three
313    biologically independent experiments are shown. Error bars denote mean $\pm$ s.e.m of three
314    technical replicates. **b,** Inhibition of recombinant live SARS-CoV-2 carrying single and
315    combination 3CL[pro] mutations by nirmatrelvir, ensitrelvir, and remdesivir. Values shown are fold
316    change in $IC_{50}$ relative to inhibition of wild-type. Representative values from a single experiment
317    from three biologically independent experiments are shown. **c,** Overlay of nirmatrelvir and
318    ensitrelvir binding to 3CL[pro]. **d,** Several of the residues involved in direct interaction with
319    nirmatrelvir. **e,** Several of the residues involved in formation of the S1 subsite. **f,** Interaction of
320    L167 with nirmatrelvir. In **c-f**, nirmatrelvir is shown in salmon, enstirelvir is shown in lime green,
321    the 3CL[pro]-nirmatrelvir complex is shown in marine, and the 3CL[pro]-ensitrelvir complex is shown
322    in gray. Protomer A is shown in marine and protomer B is shown in green. Hydrogen bonds are
323    indicated as black dashes. The 3CL[pro]-nirmatrelvir complex and 3CL[pro]-ensitrelvir complex were
324    downloaded from PDB under accession codes 7VH8 and 7VU6, respectively.

325

326    **Extended Data Fig. 1**. **Growth assays with SARS-CoV-2 passaged in Vero E6 cells. a-d,**
327    Growth was quantified for lineage A (**a**), lineage B (**b**), lineage C (**c**), and unpassaged SARS-
328    CoV-2 (**d**, denoted as WT-P0) in comparison to SARS-CoV-2 passaged without nirmatrelvir for
329    30 passages (denoted as WT-P30). Vero E6 cells were infected with 200 $TCID_{50}$ of the indicated
330    viruses and viral RNA was quantified at the indicated time points. **e,** The slope during the
331    exponential phase (between 11 and 24 hours post-infection) of growth for the indicated viruses.

332

333      **Extended Data Fig. 2**. **Mutations in the 11 3CL$^{pro}$ cut sites found in passage 16 from the 53**

334      **wells passaged in Huh7-ACE2 cells.** Dots indicate wild-type at that cut site.

335

336      **Extended Data Fig. 3. Phylogenetic tree of sequences from passaging in Huh7-ACE2 cells.**

337      Only sequences with mutations are shown. Sequences are denoted as passage number, followed

338      by the well number. Mutations that arose along particular branches are annotated in red, "-"

339      denotes when a mutation appears to be lost from a particular branch.

340

341      **Extended Data Fig. 4. Mutations studied as isogenic recombinant SARS-CoV-2 overlaid**

342      **onto the 3CL protease structure.** The Cα of each residue that was mutated is denoted with a

343      red sphere. The 3CL$^{pro}$-nirmatrelvir complex was downloaded from PDB under accession code

344      7VH8.

345

346      **Extended Data Fig. 5. Raw IC$_{50}$ values for recombinant live SARS-CoV-2 carrying single**

347      **and combination 3CL$^{pro}$ mutations by nirmatrelvir, ensitrelvir, and remdesivir.**

348      Representative values from a single experiment from three biologically independent experiments

349      are shown.

350

351      **Extended Data Fig. 6. Individual inhibition curves of recombinant live SARS-CoV-2**

352      **carrying single and combination 3CL$^{pro}$ mutations by ensitrelvir and remdesivir.**

353      Representative curves from a single experiment from three biologically independent experiments

354      are shown. Error bars denote mean ± s.e.m of three technical replicates.

355

356      **Extended Data Fig. 7. Inhibition of passage 30 of SARS-CoV-2 passaged in Vero E6 cells by**

357      **nirmatrelvir, ensitrelvir, and remdesivir. a,** Raw IC$_{50}$ values. **b,** Fold change relative to

358      inhibition of wild-type.

359

360      **Extended Data Fig. 8. Frequencies of identified 3CL$^{pro}$ mutations in GISAID. a,** All

361      occurrences of the indicated mutations were tabulated from GISAID. **b,** All occurrences of the

362      indicated mutations were tabulated from GISAID in the three months prior to EUA (9/22/2021 to

363      12/22/2021) or after EUA (3/26/2022 to 6/26/2022).

364

365 **Supplemental Table 1**. **Raw sequencing results for passaging in Huh7-ACE2 cells.** Samples

366 are denoted as passage number, followed by well number. Cut site mutations are denoted as "cs".

367

368 **Supplemental Table 2. GenBank Accession IDs for sequences from passaging in Vero E6**

369 **cells.**

545

546    **Methods**

547

548    **Compounds**

549    Nirmatrelvir was purchased from Aobius, ensitrelvir was purchased from Glixx Laboratories,

550    and remdesivir was purchased from Selleckchem.

551

552    **Cells**

553    Vero E6 cells were obtained from ATCC (Catalog #CRL-1586), HEK293T cells were obtained

554    from ATCC (Catalog #CRL-3216), and Vero E6-TMPRSS2-T2A-ACE2 cells were obtained

555    from BEI Resources (Catalog #NR-54970). Huh7-ACE2 cells were generated previously[33,39].

556    Cell morphology was visually confirmed prior to use and all cell lines tested mycoplasma

557    negative. All cells were maintained at 37 °C under 5% $CO_2$.

558

559    **In vitro selection for SARS-CoV-2 resistance to nirmatrelvir in Vero E6 cells**

560    To select for the development of drug resistance against nirmatrelvir, WA1 (SARS-CoV-2,

561    USA-WA1/2020 strain) was cultured in the presence of increasing concentrations of nirmatrelvir

562    and passaged 30 times. Virus isolates recovered from the culture at various passages were then

563    characterized for their resistance to nirmatrelvir and their replication capacity.

564

565    To initiate the passaging, Vero E6 cells were seeded in a 24 well-plate at a density of $1 \times 10^5$

566    cells per well in complete media (DMEM + 10% FCS + penicillin/streptomycin), and then the

567    drug and virus were added the following day. The drug was prepared in a three-fold dilution

568    series based on the original $IC_{50}$ of the drug. The virus was added at 5,000 $TCID_{50}$ per well.

569    Three days post-infection, each well was scored for cytopathic effects (CPE) in a range of 0 to

570    4+ based on comparison to control wells as previously described[40], and 100 µL of the

571    supernatant from the well with a CPE score equal to or greater than 2+ was passaged to each well

572    in the next culture plate. The passage culture was set up in triplicate (lineages A, B, and C) and

573    the passaging was performed independently, i.e., viruses in lineage A were kept within the

574    lineage A series of wells at every passage. Along with the cultures passaged with nirmatrelvir,

575    WA1 was passaged without nirmatrelvir in two independent wells to serve as a passage control.

576

577    IC$_{50}$s for each lineage in the passaging were determined based on the CPE scores at day 3 of each

578    passage. IC$_{50}$ values were derived by using DeltaGraph (Red Rock Software).

579

580    **Sequencing of SARS-CoV-2 passaged in Vero E6 cells**

581    For the SARS-CoV-2 passaged in Vero E6 cells, passages were sequenced by Sanger sequencing

582    or by Nanopore sequencing. For Sanger sequencing, viral RNA was isolated from the culture

583    supernatant with QIAamp® Viral RNA Mini Kit (Qiagen), reverse transcribed to cDNA with

584    Superscript IV™ Reverse Transcriptase (Thermo Fisher) and the priming primer, nsp5.R1, and

585    subjected to nested PCR with Platinum™ SuperFi II (Thermo Fisher) to obtain the full length

586    nsp5    gene.    The    primers    for    the    first    PCR    are    nsp5.F1:    5'-

587    GTAGTGATGTGCTATTACCTCTTACGC-3'    and    nsp5.R1:    5'-

588    GCAAAAGCAGACATAGCAATAATACC-3'. The primers for the second PCR are nsp5.F2: 5'-

589    CTTCAGTAACTCAGGTTCTGATGTTCT-3'    and    nsp5.R2:    5'-

590    ACCATTGAGTACTCTGGACTAAAACTAAA-3'. Both PCRs were run with the same

591    condition of 98 °C for 30 s, 25 cycles of 98 °C for 15 s, 60 °C for 10 s, and 72 °C for 1 min,

592    followed by 72 °C for 5 min. The PCR products were purified and sequenced (Genewiz).

593    Mixtures of viruses were determined by inspecting sequencing chromatograms. The sequences

594    were analyzed using Lasergene software (DNASTAR).

595

596    For Nanopore sequencing, viral RNA was isolated from the culture supernatant with QIAamp®

597    Viral RNA Mini Kit (Qiagen), and then the Midnight RT PCR Expansion kit and Rapid

598    Barcoding kits (Oxford Nanopore) were used to amplify and barcode overlapping 1,200 bp

599    amplicons tiled across the viral genome[41,42]. An Oxford Nanopore GridION with R9.4.1 flow

600    cells was used for sequencing. Basecalling was performed in MinKNOW v22.05.1. Consensus

601    sequence generation was performed using the ONT Epi2Me ARTIC Nextflow pipeline v0.3.16

602    (https://github.com/epi2me-labs/wf-artic). Pangolin 4.0.6 with UShER v1.6 was used for

603    parsimony-based lineage assignment. Sequences have been deposited to GenBank (ON924329-

604    ON924335, ON930401-ON930431) (**Supplemental Table 2**).

605

606    **Inhibition assay with SARS-CoV-2 passaged in Vero E6 cells**

33

607 To characterize the inhibition of passaged viruses, each of the viruses were first propagated in
608 Vero E6 cells in the absence of drug and titrated by the Reed-Muench method[43]. Vero E6 cells
609 were then seeded in 96 well-plates at a density of $1.5 \times 10^4$ cells per well in complete media. The
610 following day, the virus was inoculated at a dose of 500 $TCID_{50}$ per well, and a two-fold dilution
611 series of inhibitor was added in quadruplicate. Three days post-infection, the level of CPE was
612 scored and the $IC_{50}$ was derived by fitting a nonlinear regression curve to the data in GraphPad
613 Prism version 9.4 (Dotmatics).

**Growth assay with SARS-CoV-2 passaged in Vero E6 cells**

616 The fitness of passaged viruses was characterized by a viral growth assay. Vero E6 cells were
617 seeded in 96 well-plates at a density of $1.5 \times 10^4$ cells per well in complete media. The following
618 day, the virus was inoculated at a dose of 200 $TCID_{50}$ per well in quadruplicate. At 6 h post-
619 infection, free virions in the culture were removed by changing of the media twice. At 11, 24, 35,
620 and 49 h post-infection, 50 µL of the culture supernatant from each well was collected and
621 replenished with an equivalent volume of fresh media. Viral RNA from each time point was
622 purified by using PureLink™ Pro 96 Viral RNA/DNA Purification Kit (Thermo Fisher) and then
623 the viral copy number in each sample was estimated by qRT-PCR using TaqPath™ 1-Step RT-
624 qPCR Master Mix (Thermo Fisher) and 2019-nCov CDC EUA Kit (Integrated DNA
625 Technologies) with 7500 Fast Dx Real-Time PCR Instrument (Applied Biosystems).

**In vitro selection for SARS-CoV-2 resistance to nirmatrelvir in Huh7-ACE2 cells**

628 To conduct selection at scale to observe as many resistance pathways as possible, SARS-CoV-2
629 infection was conducted in five 96 well-plates, thereby allowing for 480 independent selection
630 lineages. We hypothesized that the use of limited number of cells allowed for a "bottleneck
631 effect" to occur, which enabled observation of rarer events that may be outcompeted from a
632 larger population.

634 To initiate the passaging, $3 \times 10^4$ Huh7-ACE2 cells per well were seeded in complete media in
635 five 96 well-plates. The following day, all wells were infected with 0.05 MOI of SARS-CoV-2-
636 mNeonGreen (a fluorescent reporter variant of USA-WA1/2020, gift of Pei-Yong Shi)[27] without
637 drug to generate passage 0 (P0). For each successive passage, cells were seeded the day prior to

34

638    infection, and then the drug and virus were added, three to four days post-infection of the
639    previous passage. The drug was initially added at 25 nM and then doubled every other successive
640    passage. Viruses were transferred between passages by overlaying 50 µL of the supernatant from
641    the previous passage. After 16 passages, all 54 wells positive for mNeonGreen signal were
642    sequenced, of which 53 lineages could be determined.

643

644    **Inhibition assay with SARS-CoV-2 passaged in Huh7-ACE2 cells**

645    To characterize the inhibition of passaged viruses, each of the viruses were first propagated in
646    Huh7-ACE2 cells in the absence of drug and titrated by the Reed-Muench method[43]. Huh7-
647    ACE2 cells were then seeded in 96 well-plates at a density of 2 x $10^4$ cells per well in complete
648    media. The following day, the virus was inoculated at a dose of 0.05 MOI per well, and a five-
649    fold dilution series of inhibitor was added in triplicate. At 24 h post-infection, the supernatant
650    was aspirated and cells were fixed with 4% PFA in PBS and stained with DAPI. Cells were then
651    imaged for DAPI and GFP using IN Cell 2000 (GE) and analyzed with CellProfiler version
652    4.0.7[44]. The $IC_{50}$ was then derived by fitting a nonlinear regression curve to the data in GraphPad
653    Prism version 9.4 (Dotmatics).

654

655    **Sequencing of SARS-CoV-2 passaged in Huh7-ACE2 cells**

656    For the SARS-CoV-2 passaged in Huh7-ACE2 cells, passages were sequenced by Illumina next-
657    generation sequencing. Viral RNA was first extracted using PureLink™ Pro 96 Viral RNA/DNA
658    Purification Kit (Thermo Fisher). Reverse transcription was carried out using Maxima H Minus
659    First Strand cDNA Synthesis Kit (Thermo Fisher) with random hexamers according to the
660    manufacturer's instructions. Briefly, 13.75 µL of viral RNA was mixed with 0.25 µL random
661    hexamers (50 ng/µL) and 1 µL dNTPs (10 mM), and incubated at 65 °C for 5 min followed by
662    4 °C for 1 min. Then, a mixture containing 4 µL 5x RT buffer, 0.25 µL enzyme mix (containing
663    Maxima H Minus RT and RNase inhibitor), and 0.75 µL $H_2O$ was added to each sample and the
664    reactions were incubated at 25 °C for 10 min, 55 °C for 30 min, and 85 °C for 5 min.

665

666    Sequencing libraries were prepared by amplifying either nine fragments tiled across the 3CL[pro]
667    open reading frame and adjacent nsp4/5 and nsp5/6 cut sites, or nine fragments containing each
668    of the remaining 3CL[pro] cut sites (see **Supplemental Table 3** for primer sequences). Primers

669    amplifying non-adjacent fragments of the 3CL$^{pro}$ were pooled together and reactions were carried

670    out in technical duplicate, for a total of four first-round PCRs per sample. Each first-round PCR

671    contained the following components: 1 µL cDNA, 0.25 µL 100 µM pooled primers, 0.4 µL 10

672    mM dNTPs, 2 µL 10x Taq buffer, 0.1 µL Taq DNA polymerase (Enzymatics), and 16.25 µL

673    H$_2$O. Cycling conditions were as follows: (1) 94 °C, 3 min, (2) 94 °C, 30 s, (3) 54 °C, 20 s, (4)

674    72 °C, 30 s, (5) Return to step #2 for 34 additional cycles, (6) 72 °C, 3 min, (7) Hold at 4 °C.

675

676    Products from the four first-round PCRs for each sample were pooled and gel purified, and a

677    second-round indexing PCR was carried out for each sample with the following reagents: 1 µL

678    template DNA, 0.25 µL each 100 µM indexing primer, 0.4 µL 10 mM dNTPs, 2 µL 10x Taq

679    buffer, 0.1 µL Taq DNA polymerase, and 16.25 µL H$_2$O. The cycling conditions were as

680    follows: (1) 94 °C, 3 min, (2) 94 °C, 30 s, (3) 54 °C, 20 s, (4) 72 °C, 30 s, (5) Return to step #2

681    for 6 additional cycles, (6) 72 °C, 3 min, (7) Hold at 4 °C.

682

683    Second round PCR products were pooled, gel purified, and sequenced on an Illumina NextSeq

684    system with 150 bp single-end reads. For select samples, sequences were confirmed using

685    nanopore sequencing (Plasmidsaurus). For samples P16-2D9, P12-1A4, and 4-3A1, the original

686    Illumina sequencing results were replaced with the Nanopore sequencing results.

687

688    For each sample, mutations and their frequencies were identified using the V-pipe computational

689    pipeline (version 2.99.2)[45], with Wuhan-Hu-1 (GenBank accession no. MN908947) set as the

690    reference sequence. Frequency thresholds for reporting mutations were set at 5% and 10% for

691    Illumina and nanopore sequencing, respectively. See **Supplemental Table 1** for absolute

692    frequencies of mutations within each sample. Raw sequencing data have been deposited to NCBI

693    Short Read Archive under BioProject Accession ID PRJNA852265 (see **Supplemental Table 4**

694    for SRA Accession IDs for each sample).

695

696    **Pathway analysis for SARS-CoV-2 passaged in Huh7-ACE2 cells**

697    Fig. 3 was constructed from lineages containing only the mutations that were found most

698    commonly in passage 16: T21I, T304I, A173V, E166V, P252L, S144A, and L50F. These

699    lineages were determined based on the frequencies of the corresponding mutations in a given

700    well at each passage. Pairs of mutants whose frequencies summed to greater than 100% were

701    assumed to co-occur on the same allele. The same logic was extended to identify triple and

702    quadruple mutants, such that if each pairwise sum of frequencies within a group of mutations

703    was greater than 100%, all mutations within that group were assumed to occur together. The

704    order in which mutations in a given lineage arose was imputed either from stepwise appearance

705    over time (e.g., passage 4 has mutation 1 and passage 8 has mutation 1 and mutation 2 at a total

706    combined frequency >100%) with increasing frequencies, or, in cases where 2 mutations arose

707    between sequenced passages and were deemed to co-occur in a single virus, by their relative

708    frequencies (e.g., if passage 4 has no mutations and passage 8 has mutation 1 at 99% frequency

709    and mutation 2 at 30% frequency, mutation 1 was assumed to have arisen first).

710

711    **Recombinant SARS-CoV-2 production**

712    A reverse genetics system based on the pBeloBAC11 bacterial artificial chromosome (BAC)

713    containing the SARS-CoV-2 genome with a NanoLuc luciferase reporter replacing ORF7a[46] (gift

714    of Luis-Martinez Sobrido) was used to produce recombinant SARS-CoV-2 harboring 3CL$^{pro}$

715    mutations. Mutants BACs were produced as previously described[33]; see **Supplemental Table 5**

716    for a list of mutagenic primers used. These BACs (2 µg each) were then transfected into

717    HEK293T cells in 12 well-plates in triplicate using Lipofectamine™ 3000 Transfection Reagent

718    (Thermo Fisher) according to the manufacturer's instructions. Two days post-transfection, cells

719    were pooled and overlaid onto Vero E6-TMPRSS2-T2A-ACE2 cells in 25 cm$^2$ flasks. After

720    three days, the supernatant was collected from these cells and clarified by centrifugation, then

721    used to infect Vero E6 cells in 75 cm$^2$ flasks. Four days post-infection, the supernatant was

722    harvested, clarified by centrifugation, and aliquoted. Viruses were stored at -80 °C prior to use.

723    An aliquot of all recombinant viruses was confirmed by nanopore sequencing for the mutation of

724    interest and for purity prior to use.

725

726    **Inhibition assay with recombinant SARS-CoV-2**

727    Viruses were first titrated to normalize input. To characterize inhibition, Huh7-ACE2 cells were

728    seeded at a density of 2 x 10$^4$ cells per well in 96 well-plates. The following day, cells were

729    infected with 0.05 MOI of virus, and treated with inhibitor in a five-fold dilution series. One day

730    post-infection, cells were lysed and luminescence was quantified using the Nano-Glo®

731    Luciferase Assay System (Promega) according to the manufacturer's instructions. $IC_{50}$s were

732    derived by fitting a nonlinear regression curve to the data in GraphPad Prism version 9.4

733    (Dotmatics).

734

735    **Growth assay with recombinant SARS-CoV-2**

736    Viruses were first titrated to normalize input. To characterize fitness, Huh7-ACE2 cells were

737    seeded at a density of 2 x $10^4$ cells per well in 96 well-plates. The following day, cells were

738    infected with 0.01 MOI of virus. At 12, 24, 36, and 48 h post-infection, cells were lysed and

739    luminescence was quantified using the Nano-Glo® Luciferase Assay System (Promega)

740    according to the manufacturer's instructions.

741

742    **Retrieval of clinical mutation frequencies**

743    COVID-19 CG was used to retrieve all clinically observed 3CL$^{pro}$ mutations from GISAID on

744    June 26, 2022, either since the start of the COVID-19 pandemic or between March 26-June 26,

745    2022, and September 22-December 22, 2021[31,47].

**Acknowledgements**

**Author contributions**

S.I., B.C., S.J.H., A.C., and D.D.H. conceived this project and approach to scaled screening for resistant viral variants. S.I. and H.M. conducted the *in vitro* passaging. S.I., H.M., B.C., S.J.H., M.K.A., A-C.U., and A.C. conducted the sequencing. S.I. and H.M. conducted the fitness and inhibition assays. B.C., S.J.H., and A.C. conducted the pathway analyses. S.I., H.M., B.C., S.J.H., M.I.L., Y.S., and A.C. generated recombinant SARS-CoV-2. Y.D., Y.G., Z.S., and H.Y. conducted the structural analyses. S.P.G. contributed to discussions of the data and analysis. S.I., H.M., B.C., S.J.H., Y.D., H.Y., A.C., and D.D.H. wrote the manuscript with input from all authors.

**Competing interests**

S.I., A.C., and D.D.H. are inventors on patent applications related to the development of inhibitors against the SARS-CoV-2 3CL protease. D.D.H. is a co-founder of TaiMed Biologics and RenBio, consultant to WuXi Biologics and Brii Biosciences, and board director for Vicarious Surgical.

**Materials availability**

Materials used in this study will be made available under an appropriate Materials Transfer Agreement.

**Data availability**

All experimental data are provided in the manuscript. The sequences of mutants from passaging in Vero E6 cells have been deposited to GenBank (ON924329-ON924335, ON930401-ON930431). The raw next-generation sequencing data of passaging in Huh7-ACE2 cells are

777    available from the NCBI Short Read Archive under BioProject Accession ID PRJNA852265.

778    The structures of the 3CL$^{pro}$-nirmatrelvir complex and 3CL$^{pro}$-ensitrelvir complex were

779    downloaded from PDB under accession codes 7VH8 and 7VU6, respectively.

780

781    **Code availability**

782    Sequencing data processing and visualization was performed using the ONT ARTIC Nextflow

783    pipeline (https://github.com/epi2me-labs/wf-artic) and the V-pipe computational pipeline

784    (https://github.com/cbg-ethz/V-pipe), both of which are publicly available software and packages.
