## Keywords: microalgae, volatile fatty acids, heterotrophy, quantitative proteomics, metabolic pathways

#### 12 Abstract

- 13 Volatile fatty acids found in effluents of the dark fermentation of biowastes can be used for
- 14 mixotrophic growth of microalgae, improving productivity and reducing the cost of the feedstock.
- 15 Microalgae can use the acetate in the effluents very well, but butyrate is poorly assimilated and can
- 16 inhibit growth above 1 gC.L<sup>-1</sup>. The non-photosynthetic chlorophyte alga *Polytomella* sp. SAG 198.80
- 17 was found to be able to assimilate butyrate fast. To decipher the metabolic pathways implicated in
- 18 butyrate assimilation, quantitative proteomics study was developed comparing *Polytomella* sp. cells
- 19 grown on acetate and butyrate at 1 gC.L<sup>-1</sup>. After statistical analysis, a total of 1772 proteins were
- 20 retained, of which 119 proteins were found to be overaccumulated on butyrate vs. only 46 on acetate,
- 21 indicating that butyrate assimilation necessitates additional metabolic steps. The data show that 22 butyrate assimilation occurs in the peroxisome via the β-oxidation pathway to produce acetyl-CoA
- butyrate assimilation occurs in the peroxisome via the  $\beta$ -oxidation pathway to produce acetyl-CoA and further tri/dicarboxylic acids in the glyoxylate cycle. Concomitantly, reactive oxygen species
- 24 defense enzymes as well as the branched amino acid degradation pathway were strongly induced.
- 25 Although no clear dedicated butyrate transport mechanism could be inferred, several membrane
- 26 transporters induced on butyrate are identified as potential condidates. Metabolic responses
- 27 correspond globally to the increased needs for central cofactors NAD, ATP and CoA, especially in
- the peroxisome and the cytosol.

#### 29 **1** Introduction

30 Mixotrophic growth combines the reduction of  $CO_2$  via photosynthesis with the oxidation of organic

31 carbon and is found in a wide range of phototrophic microorganisms such as cyanobacteria and

- 32 microalgae (Perez-Garcia and Bashan, 2015). This trophic mode is generally the most efficient in terms
- 33 of biomass productivity (Zhan et al., 2017). Some photosynthetic microalgae also have heterotrophic
- 34 capacities, i.e. they can grow in the absence of light on reduced carbon sources (Round, 1980).
- 35 Although glucose can yield very high biomass productivities (Perez-Garcia et al., 2011), it is an

36 expensive substrate that is not economical for many microalgal biorefinery applications with lower 37 added value such as biofuels, green chemistry platform molecules, aquaculture and biofertilizer (Acién Fernández et al., 2019). It has been proposed to use organic acids produced by the fermentation of 38 39 biowaste material as feedstock to lower the cost (Delrue et al., 2016; Turon et al., 2016; Chalima et al., 40 2017; Karnaouri et al., 2020). Dark fermentation (DF) of organic matter by microbial consortia is a 41 sustainable n method for  $H_2$  production that compares favorably to other process in terms of  $CO_2$ 42 footprint (Dincer and Acar, 2015; Moscoviz et al., 2018). In this context it is warranted to intensify 43 research on downstream coupled processes such as mixotrophic cultivation of microalgae on DF 44 effluents (DFE). Depending on the conditions, DFEs contain different ratios of volatile fatty acids 45 (VFA) alongside some lactate and ethanol. In general, mostly acetate and butyrate are present, in a 46 molar ratio of 0.66 on average (Turon et al., 2016; Moscoviz et al., 2018).

47 While microalgae that use glucose can usually also use acetate, many algae can grow on acetate but 48 not on glucose, e.g. Chlamydomonas reinhardtii (Harris, 1989). Capacities for the use of other 49 substrates such as lactate, ethanol and butyrate are less common and vary widely, even within the same 50 species e.g. Euglena gracilis var bacillaris or urophora (Neilson and Lewin, 1974; Hosotani et al., 51 1988). By far the most abundant VFA in DFEs is butyrate, but it is toxic for many bacteria and is 52 known to be poorly used by microalgae (Turon et al., 2015; Lacroux et al., 2020, 2021). A generalized 53 toxicity effect of VFAs is observed as the extracellular pH approaches the pKa value because cells are 54 permeable to the protonated form, resulting in deleterious effect on the cell metabolism and integrity 55 (Lacroux et al., 2020). The toxicity threshold for butyrate (as butyric acid) is 5-fold lower than for 56 acetic acid in some species, explaining why it is a poor carbon source. Algal growth on butyrate will 57 thus require more care in adapting the pH and concentration to remain below the observed species-58 specific toxicity threshold. However, this will be inadequate to reach growth rates similar to those on 59 acetate. It is therefore crucial that butyrate metabolism be studied in detail in order to remove metabolic 60 bottlenecks in its assimilation.

61 Butyrate assimilation is well studied in microorganisms such as the sulfate reducer Desulfosarcina cetonica (Janssen and Schink, 1995), the non-sulfur purple bacterium Rhodospirillum rubrum (De 62 Meur et al., 2020), yeasts i.e. Candida ingens (Garrison et al., 1985) or Yarrowia lipolytica (Llamas et 63 64 al., 2020) and also in human colonocytes, for which bacteria-produced butyrate is the primary energy 65 source (Roediger, 1982; Fleming et al., 1991). Colonocytes import butyrate via the monocarboxylate 66 transporter (MCT), a 45-kDa plasma membrane protein with 12 transmembrane segments that 67 symports H+ with the butyrate anion (Cuff et al., 2005). Butyrate is subsequently imported into the 68 mitochondrial matrix where it undergoes  $\beta$ -oxidation to acetyl-CoA, which in turn enters the TCA 69 cycle resulting in the production of NADH. The first step of  $\beta$ -oxidation is its activation into butyryl-70 CoA via an ATP-dependent butyryl-CoA synthetase, followed by the conversion into crotonyl-CoA 71 by butyryl-CoA dehydrogenase, into hydroxy-isobutyryl-CoA by enoyl-CoA hydratase, then into 72 acetoacetyl-CoA by hydroxybutyryl-CoA dehydrogenase and finally into acetyl-CoA via acetoacetyl-73 CoA thiolase (De Preter et al., 2012). A different assimilation metabolism was uncovered by a 74 proteomic approach in the non-sulfur purple bacterium R. rubrum (De Meur et al., 2020), where acetyl-75 CoA is used to activate butyrate via butyryl-CoA:acetate CoA transferase under photoheterotrophic 76 conditions. Homologs of most enzymes potentially involved in butyrate assimilation as found in human 77 colonocytes have been identified in C. reinhardtii, the best studied algal species (Li-Beisson et al., 78 2019). However, nothing is known about the enzyme(s) that may be involved in formation of butyryl-79 CoA in algae, in particular their subcellular localization. The case of acetyl-CoA is better studied. In 80 the model alga C. reinhardtii, acetyl-CoA is formed from acetate by acetyl-CoA synthase, purportedly 81 in peroxisomes, and further utilized in the glyoxylate cycle to form products such as malate, citrate and 82 succinate that can be further exported to other cell compartments (Lauersen et al., 2016). The import 83 of butyrate into microalgal cells and the associated metabolic responses and their intracellular 84 localization remain to be studied.

85 The heterotrophic chlorophyte *Polytomella* sp. SAG 198.80 is to our knowledge the alga for which

- the fastest butyrate assimilation has been described (Wise, 1955, 1959), and more recently by the
- 87 authors of this work (Lacroux et al. 2022). The fact that *Polytomella* has lost photosynthetic activity
- 88 allows focusing on the assimilation pathways, avoiding interactions with photosynthetic metabolism
- that complicate analysis (van Lis and Atteia, 2004; Johnson and Alric, 2013). In this study, a
- 90 quantitative proteomics approach is used to decipher the metabolic pathways specifically involved in
- 91 the assimilation of butyrate by *Polytomella*, based on the comparison to acetate as reference
- 92 metabolism as this is the simplest entry of organic carbon into central carbon metabolism.

#### 93 2 Material and methods

#### 94 **2.1** Strain and culture conditions

95 *Polytomella* sp. SAG 198.80 was obtained from the SAG culture collection (Goettingen, Germany).

- 96 It was grown on synthetic media referred to as HAP (acetate) or HBP (butyrate), based on Tris-
- 97 Acetate-Phosphate (TAP) medium used for the green alga C. reinhardtii (Harris, 1989), in which the
- 98 Tris buffer is replaced by HEPES 0.1 M, at pH 7. Beijerincks solution (40X) was used at 25 mL.L<sup>-1</sup>
- 99 leading to an ammonium  $(NH_4^+)$  concentration of 7.5 mM, 0.6 mM of MgSO<sub>4</sub> and 0.3 mM of CaCl<sub>2</sub>.
- 100 To adjust nutrients to the Redfield C:N:P ratio of 106:16:1, corresponding to 83.3:12.6:0.8 mM for 1
- 101 g carbon per liter (1.0  $g_C.L^{-1}$ ), the proper amount of 1 M NH<sub>4</sub>Cl (5 mL) and 1 M K<sub>2</sub>HPO<sub>4</sub> (0.8 mL) 102 stock solutions were added. Hutner's trace elements were used at 1 mL.L<sup>-1</sup> (Hutner, 1972). As carbon
- stock solutions were added. Hutner's trace elements were used at 1 mL.L<sup>-4</sup> (Hutner, 1972). As carbon source, acetate or butyrate were added as sodium salts at  $1.0 \text{ g}_{\text{C}}$ .L<sup>-1</sup> (41.7 mM acetate, 20.8 mM
- butyrate) and pH medium was adjusted to 7.0 (HCl) prior to sterilization at 121°C for 20 min. After
- 105 cooling, 100 µL.L<sup>-1</sup> was added of a stock of vitamin B1 (50 mM), biotin (1 mM) and cyanocobalamin
- 106 (1 mM), sterilized over a 0.2 µm filter. Precultures were maintained on HAP medium containing 20
- 107 mM HEPES and were used to inoculate HAP and HBP media to initial optical density at 750 nm
- 108  $(OD_{750}) = 0.05$ . The inoculum was prepared by collecting preculture cells in their exponential phase
- 109 via centrifugation at 2500 g for 10 min, and resuspending them in Phosphate Buffered Saline to a
- 110 final  $OD_{750} = 5$ . Cultures were done in 500mL Erlenmeyer flasks filled with 200 mL medium under
- 111 dim light at 25°C and without agitation.

#### 112 2.2 Biomass and VFA measurement

113 Biomass growth was followed by measuring optical density at 750 nm (OD750), using a Helios

- 114 Epsilon spectrophotometer. OD750 was measured by placing 1 mL of liquid culture in a cuvette and
- 115 comparing to distilled water. The sample was diluted when necessary so that OD750 < 0.6. Biomass
- 116 production was expressed in  $g.L^{-1}$  dry weight (DW) deduced from OD750 determination. To
- 117 calculate the biomass DW from OD750 values, a correlated factor was used, determined to be 1.0774
- 118 ( $R^2 = 0.977$ ). This correlation factor was obtained from a calibration curve gathering 70 data points
- collected during separated experiments, at various growth stages (stationary phase excluded) and
- 120 growth conditions (HAP or HBP medium). To determine biomass DW during these experiments,
- between 5 and 25 mL (depending on growth stage) biomass was centrifuged (3000 rpm, 10 min).
- 122 Supernatant was discarded, and pellet rinsed with one volume of phosphate buffer saline. Biomass
- 123 was centrifuged again, supernatant discarded and pellet resuspended in 10 mL distilled wated. The
- biomass was transferred in a pre-dried and pre-weighed aluminium crucible and dried overnight at105°C.
- 126 For VFA measurements, samples from fresh cultures were immediately centrifuged, the supernatant
- filtered over  $0.2 \,\mu\text{m}$  cut-off filters and frozen at -25°C until analyzed. The VFA concentrations were
- 128 determined by gas chromatography. A 500 μL aliquot of supernatant was mixed with 500 μL of

129 internal standard solution (ethyl-2-butyric acid,  $1 \text{ g} \cdot \text{L}^{-1}$ ). The GC system consisted in a Perkin Clarus

130 580 model equipped with capillary column Elite-FFAP crossbond®carbowax® (15 m) maintained at

131 200 °C and with N<sub>2</sub> as the gas vector (flow rate of 6 mL·min<sup>-1</sup>) with a flame ionization detector (FID)

132 maintained at 280 °C (PerkinElmer, USA)

#### 133 2.3 Analysis of total lipids and sugars

134 Samples from fresh cultures were immediately centrifuged, the supernatants were discarded and the

- pellets stored at -25°C until used. Prior to analysis, the pellet was thawed, resuspended in 100µl
- distilled water and added to 10 mL glass tubes for either lipid or sugar measurement. Total lipid
- 137 concentrations in the algal samples were determined by the phosphovanillin method (Mishra et al.,
- 138 2014). Phosphovanillin reagent was freshly prepared by first dissolving 0.6 g vanillin in 10 ml
- ethanol, and then adding 90 ml deionized water and 400 ml of  $H_3PO_4$  (85%). The resulting reagent was stored in the dark. First, 2 mL  $H_2SO_4$  (98%) were added in the tubes containing microalgae cells.
- 141 The tubes were heated 10 min at  $100^{\circ}$  C and cooled on ice. The reaction was initiated by addition of
- 142 5 mL phosphovanillin reagent prior incubation for 15 min at 37° C. Tubes were periodically shaken
- 143 by inversion. After cooling, optical density of suspensions was measured at 530 nm with an
- 144 Aqualytic® spectrometer and compared to distilled water. Calibration curves were obtained using
- 145 canola oil.

146 Total sugars were measured by the anthrone method (Yemm and Willis, 1954). Anthrone reagent was

147 prepared by dissolving 200 mg of anthrone in 100 mL of H<sub>2</sub>SO<sub>4</sub> (98%). Two mL of anthrone reagent

148 were added in the tubes containing microalgae. Tubes were cooled down on ice and then incubated at

- 149 100° C for 10 min. After cooling, absorbance was measured at 625 nm with an Aqualytic®
- 150 spectrometer and compared to distilled water. Calibration curves were obtained using glucose
- 151 solution.

#### 152 **2.4** Calculation of specific rates and product yield in growing cultures

153 The biomass productivity  $P_x$  ( $g_{dw}$ .L<sup>-1</sup>.d<sup>-1</sup>) and the specific growth rate  $\mu_x$  (d<sup>-1</sup>) were calculated 154 according to equations (1) and (2):

155  
156 
$$P_x = \frac{X_f - X_0}{t_f - t_0}$$
 (1)

158  $\mu_x = \frac{\ln(X_f/X_0)}{(tf-t_0)}$  (2)

159

160 where  $X_f$  and  $X_0$  are the biomass concentrations at t=final (h) and at t=0h.

161 The biomass yield Y ( $g_{dw}$ . $g_{sub}^{-1}$ ) was estimated according to equation (3):

162  
163 
$$Y_s = \frac{S_0 - S_f}{t_f - t_0}$$
(3)

164

- 165 Where  $S_f$  and  $S_0$  are substrate concentrations (g.L<sup>-1</sup>) at t=final (h) and at t=0h.
- 166 Statistical analysis was performed using GraphPad Prism V 8.0.2.
- 167 168

#### 169 **2.5** Mass spectrometry-based proteomic analyses

170 The total proteome of *Polytomella* sp. grown either on acetate or butyrate (three biological replicates

- 171 per condition) were stacked in the top of a 12% SDS-PAGE resolving gel before in-gel digestion
- using modified trypsin (sequencing grade, Promega), as previously described (Casabona et al., 2013).
- 173 The resulting peptides were analyzed by online nanoliquid chromatography coupled to MS/MS
- 174 (Ultimate 3000 RSLCnano and Q-Exactive HF, Thermo Fisher Scientific) using a 80 min gradient.
- For this purpose, the peptides were sampled on a precolumn (300 μm x 5 mm PepMap C18, Thermo
  Scientific) and separated in a 75 μm x 250 mm C18 column (Reprosil-Pur 120 C18-AQ, 1.9 μm, Dr.
- 177 Maisch). The MS and MS/MS data were acquired by Xcalibur (Thermo Fisher Scientific).
- Peptides and proteins were identified by Mascot (version 2.6.0, Matrix Science) through concomitant
- searches against a homemade *Polytomella* sp. database, a homemade classical database containing
- 180 the sequences of classical contaminant proteins found in proteomic analyses (human keratins, trypsin,
- 181 etc.), and the corresponding reversed databases. Trypsin/P was chosen as the enzyme and two missed
- 182 cleavages were allowed. Precursor and fragment mass error tolerances were set at respectively at 10
- 183 ppm and 25 mmu. Peptide modifications allowed during the search were: Carbamidomethyl (C,
- 184 fixed), Acetyl (Protein N-term, variable) and Oxidation (M, variable). The Proline software
- 185 (Bouyssié et al., 2020) was used for the compilation, grouping, and filtering of the results
- 186 (conservation of rank 1 peptides, peptide length  $\geq$  7 amino acids, peptide-spectrum-match score  $\geq$  25,
- allowing to reach a false discovery rate of peptide-spectrum-match identifications < 1% as calculated
- 188 on peptide-spectrum-match scores by employing the reverse database strategy, and minimum of one
- specific peptide per identified protein group). Proline was then used to perform MS1 quantification
- 190 of the identified protein groups based on specific peptides.
- 191 Statistical analysis was performed using the ProStaR software (Wieczorek et al., 2017).
- 192 The mass spectrometry proteomics data have been deposited to the ProteomeXchange Consortium
- via the PRIDE (Perez-Riverol et al., 2022) partner repository with the dataset identifier PXD035155.
- 194 Proteins identified in the contaminant database, and proteins detected in less than three replicates of
- one condition were removed. After log2 transformation, abundance values were normalized by the
- 196 vsn method before missing value imputation (slsa algorithm for partially observed values in the 197 condition and DetOuantile algorithm for totally absent values in the condition). Statistical testing was
- condition and DetQuantile algorithm for totally absent values in the condition). Statistical testing was
   conducted with limma, whereby differentially expressed (DE) proteins were sorted out using a
- 198 Conducted with Innina, whereby differentiatly expressed (DE) proteins were sorted out using a 199 log2(fold change) cut-off of 0.6 and a p-value cut-off of 0.004, allowing to reach a false discovery
- 200 rate < 1% according to the Benjamini-Hochberg method.
- 201 Intensity-based absolute quantification (iBAQ, Schwanhäusser et al., 2011) values were calculated
- 202 from MS intensities of specific peptides. For each sample, the iBAQ value of each protein was
- 203 normalized by the summed iBAQ value of all proteins, before summing the values of the three
- 204 replicates to generate the final iBAQ value of each condition.

#### 205 2.6 Bioinformatic analyses

- 206 The assembly and structural annotation of the genome sequence of *Polytomella* sp. was described
- 207 previously (van Lis et al., 2021). The predicted proteins (genome to be released at an later date) were
- 208 used for the construction of the database for proteomics analysis. The functional annotation of the
- 209 proteins that were identified by proteomics (1772 sequences) and further attribution of metabolic
- 210 categories was done using Mercator4 V3.0 (<u>https://plabipd.de/portal/mercator4</u>), and used to project
- 211 the fold change data onto a metabolic overview SVG image file, using the MapMan program
- (https://plabipd.de/portal/mapman) (Schwacke et al., 2019) used as stand-alone desktop application
   and Inkscape (https://inkscape.org/release/inkscape-1.2.1/) to modify the image file.
- 214 Final metabolic pathway reconstructions were based on metabolic maps made in KEGG mapper
- 215 using KEGG and EC codes from BlastKOALA and KofamKOALA (HMM) homology searches at
- 216 KEGG (<u>https://www.genome.jp/kegg/</u>) and by using EggNOG (Huerta-Cepas et al., 2019). These

217 programs were also used to confirm and adjust annotations from Mercator where necessary, as well

as manual BLAST searches using the UniProt database (https://www.uniprot.org) and the *C*.

219 *reinhardtii* genome at Phytozome 13 (https://phytozome-next.jgi.doe.gov). OmicsBox 1.3.11

220 (https://www.biobam.com/omicsbox) genome blast was used with the genomes of *Chlamydomonas* 

221 reinhardtii (Uniprot UP000006906) and Chlorella sorokiniana (Uniprot UP000239899) to obtain

equivalent enzyme identities in these two model microalgae. For subcellular localization predictions,

DeepLoc (Almagro Armenteros et al., 2017) and PredAlgo (Tardif et al., 2012) were used with the limitation that the latter does not predict peroxisomal targeting. Therefore further searches for

potential peroxisome targeting signals in *Polytomella* protein sequences were done with the PTS1

predictor (https://mendel.imp.ac.at/pts1/) (Neuberger et al., 2003) or manually based on (Gonzalez et

226 predictor (https://mendel.imp.ac.at/pts1/) (Neuberger et al., 2003) or manually based

227 al., 2011).

#### 228 **3 Results & Discussion**

#### 229 **3.1** *Polytomella* sp. is a suitable model for the study of butyrate metabolism

230 At the basis of this work is the choice of *Polytomella* sp. as model algal species for the study of butyrate 231 metabolism. The genus Polytomella belongs to the Reinhardtinia clade of Volvocine algae (Craig et 232 al., 2021) and has diverged from a *Chlamydomonas*-like ancestor after having lost photosynthesis along 233 with the chloroplast genome (Smith and Lee, 2014). Chlamydomonas reinhardtii only grows 234 efficiently on acetate (Harris, 2001), so the highly versatile heterotrophic metabolism allowing 235 Polytomella to grow on a multitude of alcohols and organic acids including butyrate (Wise, 1955, 1959; 236 Round, 1980; de la Cruz and Gittleson, 1981) may have been partly acquired after the divergence. The 237 availability of an annotated genome sequence of *Polytomella* sp. (van Lis et al., 2021) allowed a global 238 proteomics approach to decipher its metabolic pathways involved in the assimilation of butyrate. Cells grown on either acetate or butyrate, at a fixed C concentration of 1.0  $g_{C}L^{-1}$  (Fig. 1) showed similar 239 growth rates of 2.37  $d^{-1} \pm 0.07$  and 2.23  $d^{-1} \pm 0.08$ , respectively (three biological triplicates). Both 240 241 carbon sources were completely consumed before 1.5 days, leading to a maximum biomass yield of 1.07  $g_{x}L^{-1}$  (x=dry weight biomass) in both conditions (Fig 1C). After organic carbon exhaustion, 242 243 biomass declined due to cell death in both conditions and cysts formation was observed (not shown). 244 Biomass growth was accompanied by sugar accumulation, with about 15% less sugar on butyrate than 245 on acetate (Fig 1D). In the related species P. agilis, the accumulated sugar was found to be essentially 246 starch (Sheeler et al., 1968). Lipid accumulation is low in both cells, with a maximum of  $73.3 \pm 3.6$ 247 mg.L<sup>-1</sup> (biomass content ~5%) on acetate and  $55.6 \pm 3.1$  mg.L<sup>-1</sup> on butyrate.

For several *Chlorella* strains it was reported that butyrate assimilation, when it occurred, was slower than acetate assimilation (Liu et al., 2013; Fei et al., 2015). Heterotrophic (dark) growth rates of *Chlorella sorokiniana* are 2.23 d<sup>-1</sup> on acetate and 0.16 d<sup>-1</sup> on butyrate (Turon et al., 2015). The ability of *Polytomella* sp. to grow on butyrate with a growth rate of 2.2 d<sup>-1</sup>, similar to that on acetate (Fig 1C), is thus remarkable.

Green microalgae tend to accumulate proteins during exponential growth and only start synthetizing storage compounds (starch, lipids) when growth conditions become suboptimal, e.g. when a micro- or macro-element such as nitrogen is limiting (Dincer and Acar, 2015). Since this fact usually implies that high biomass productivity is accompanied by low starch or lipid accumulation, continuous cultivation is less relevant (Adams et al., 2013). Accumulation of high levels of starch during the exponential growth phase is thus another distinctive and interesting trait of *Polytomella* sp..

#### 259 **3.2** Comparing global proteomes

260 Cultures of *Polytomella* sp. growing on acetate and butyrate were sampled during the exponential phase 261 (arrows in Fig. 1). Total cell proteins were first analyzed on SDS-PAGE stained with Coomassie Blue

262 G250. From the comparison of the protein profiles (Fig. 2A) it is inferred that butyrate elicits major 263 changes in protein levels, and a clear upregulation of 3 proteins of 28, 38 and 60 kDa can be observed 264 (indicated by asterisks, Fig 2A). To study more in detail the proteomic responses to butyrate, total 265 proteins from acetate and butyrate grown cells were subjected to mass spectrometry (MS)-based label-266 free quantitative proteomic analysis. A volcano plot depicts the acetate vs butyrate fold change (FC, a 267 direct measure of the relative protein abundance between both conditions) and the associated statistical 268 significance (limma p-value) for each protein (Fig. 2B). The log2(FC) values varied between 4 and -269 10, corresponding to an FC of 16 and 0.001, where the latter value indicates a 1000-fold upregulation 270 on butyrate. A total of 1772 proteins were retained after statistical analysis, of which 119 were found 271 to be significantly more abundant on butyrate compared to only 46 on acetate, and usually with a lower 272 FC. This shows that growth on butyrate is accompanied by overaccumulation of a larger set of proteins 273 than on acetate, which may indicate that butyrate needs more metabolic steps to enter central carbon 274 metabolism than acetate.

275

#### 276 **3.3** Proteomic responses per metabolic category

277 The 1772 proteins identified by MS-based proteomics were grouped into 27 metabolic categories using 278 the Mercator program, which was conceived for plant sequences but can also be used for microalgae 279 (May et al., 2008; Davidi et al., 2014), including *Polytomella* sp (Fuentes-Ramírez et al., 2021). Several 280 other databases were used to confirm identities in case of doubt especially for the entries listed in Table 281 I, as described in the Material and Methods section. Any redundant entries in the Mercator results were 282 removed and retained in only one metabolic category. Of the 1772 statistically relevant proteins, 217 283 could not be annotated (12.2%) and 411 were annotated but could not be assigned to any Mercator 284 category (23.2%) (Fig 3A). These percentages are similar or significantly lower than found in whole 285 cell proteomic studies of other microalgae such as C. reinhardtii or Dunaliella bardawil (May et al., 286 2008; Davidi et al., 2014). A number of proteins that were not readily categorized but to which an EC 287 number could be assigned, were included in the category 'Enzyme classification'. The "protein 288 biosynthesis" category is the metabolic category most represented with 209 proteins (11.8% of total 289 proteins), followed by "protein homeostasis" (99 proteins; 5.6%) and "lipid metabolism" (84 proteins; 290 4.7%) (Fig. 3A). In addition, we calculated the cumulated iBAQ values to yield the total protein 291 abundance per Mapman category in both conditions (Fig. 3B). The iBAQ value of a protein reflects its 292 intra-sample abundance, and this calculation thus tries to estimate the impact of a condition on the 293 accumulation of proteins related to a certain pathway. Among identified proteins, those in the 294 categories "protein biosynthesis" and "cellular respiration" contribute most to the cumulative iBAQ 295 value. Two major differences are seen between the two conditions. For acetate there is a more 296 pronounced accumulation of proteins involved in protein biosynthesis (29% compared to 19.2% for 297 butyrate), whereas for butyrate an enrichment is observed for proteins involved in lipid metabolism 298 (11.8% vs 4.5% for acetate). It is noted that the two unassigned categories (annotated or not annotated) 299 each contribute proportionally much less to the total iBAQ than to the number proteins, reflecting the 300 fact that high abundance proteins are more likely to be attributed to a specific function.

301 Focussing on proteins differentially-expressed (DE) between the acetate and butyrate conditions, the 302 above global trend is confirmed but a more detailed picture emerges (Fig. 4). Relative to acetate, more 303 proteins are overaccumulated on butyrate in the categories related to primary metabolism *i.e.* cellular 304 respiration (4), carbohydrate metabolism (17), amino acid metabolism (10) and lipid metabolism (25), 305 as well as the categories redox homeostasis (9), solute transport (10) and coenzyme metabolism (5). In 306 contrast, acetate grown cells overaccumulate more proteins involved in homeostasis (6), biosynthesis 307 (13) and protein translocation (2) as well as in RNA processing (4), processes that can be considered 308 as necessary for general cellular maintenance. Comparing the proportion of FC proteins in each

309 category to the proportion in these categories of the 1772 identified proteins using the Exact Fisher's 310 test, a significant enrichment in butyrate was obtained for the categories carbohydrate- and lipid 311 metabolism, redox homeostasis and solute transport. For the acetate condition, the protein biosynthesis 312 and protein homeostasis were found enriched. Overall, it is clear that the butyrate utilization mobilizes 313 a higher number of proteins, suggesting a more profound metabolic response compared to acetate.

314

#### 315 **3.4** Metabolic pathways involved in butyrate response

316 To obtain a global metabolic representation of *Polytomella* sp., MapMan was used to project the FC 317 values of individual proteins onto the different metabolic pathways. In section 3.5 these pathways will 318 be discussed in detail. In the category lipid metabolism, the highest FC values are for enzymes of fatty 319 acid synthesis, fatty acid degradation and the glyoxylate cycle (Fig. 5). The enzymes of the latter two 320 functional groups are predicted to localize mostly to the peroxisomes, based on peroxisomal targeting 321 prediction via software algorithms, manual analysis of the presence of peroxisomal targeting sequences 322 PST1 and PST2, and/or the relatedness to peroxisomal enzymes in the green alga C. reinhardtii (Table 323 I; see also suppl. Table I). Peroxisomes, organelles primarily dedicated to peroxide detoxification, seem 324 to play a major role in butyrate assimilation in *Polytomella*. Butyrate being a fatty acid, the MapMan 325 category "fatty acid degradation" is expected, and corresponds to what is described for other organisms 326 (De Preter et al., 2012; De Meur et al., 2020). The glyoxylate cycle upregulation is in line with the fact 327 that butyrate degradation leads to the production of 2 molecules of acetyl-CoA, which together with 328 glyoxylate is the central entry point into the cycle. Fatty acid synthesis is also upregulated and is related 329 in part to the activation with Coenzyme A, and seems to indicate cellular shift in the production sites 330 and levels of acetyl-CoA (Pietrocola et al., 2015). Fatty-acid synthesis intermediates may for example 331 be needed for the production of cofactors such as biotin and lipoic acid (Alban et al., 2000). Indeed, 332 several enzymes involved in cofactors synthesis were found to be strongly upregulated as well. In 333 addition, several enzymes (such as catalase) involved in antioxidant defense were strongly upregulated 334 (Fig. 5), which can be directly or indirectly a consequence of the degradation of butyrate, notably by 335 the formation of H<sub>2</sub>O<sub>2</sub> at the site of the acyl-CoA oxidase (ACX) enzyme (Kato et al., 2021) but also 336 due to the fact that butyrate is 25% more reduced compared to acetate, leading to an increased 337 generation of reducing equivalents such as NADH.

- 338 The amino acid metabolic pathway most affected by the C-source is the formation and subsequent 339 degradation of branched chain amino acids (BCAAs). It appears to take place largely in the peroxisome 340 based on the subcellular targeting predictions of the corresponding proteins, unlike in its close relative 341 C. reinhardtii where it occurs in the mitochondria (Liang et al., 2019). It is noted that some of these 342 enzymes are partitioned by MapMan into the lipid metabolism category. Carbohydrate metabolism, 343 notably starch degradation, is upregulated on butyrate, reflected in the lower starch content in butyrate 344 grown cells (Fig. 1D), which suggests an increased mobilization of glucose into pyruvate for 345 downstream metabolic pathways. Finally, several peroxisomal and mitochondrial-type solute transporters are clearly induced on butyrate, which indicates increased exchange of a variety of 346 347 metabolites between these compartments.
- 348

#### 349 **3.5** Reconstruction of the butyrate metabolic network

350 A list of those proteins that exhibit the most pronounced fold change sorted according to the Mercator

351 categories is presented in Table I, alongside the most relevant data pertaining to protein databases and

proteomic parameters. Protein identities were obtained by homology searches using Mercator and other

353 programs for further validation (see material and methods), and their functional characteristics and

354 their known or predicted intracellular localization were used to reconstruct the most important 355 metabolic pathways in Polytomella sp. cells growing on butyrate relative to acetate. The most 356 pronounced enrichment of enzymes involved in butyrate assimilation is found in the peroxisomes, 357 small spherical organelles (0.2-1.5µm) that lack DNA and are surrounded by a single membrane that 358 derives from the endoplasmic reticulum (Hu et al., 2012). Originally described as organelles that harbor 359 oxidases that produce H<sub>2</sub>O<sub>2</sub> and catalase for its detoxification (De Duve and Baudhuin, 1966), they are known to compartmentalize a large diversity of functions among which fatty acid β-oxidation 360 361 (Gabaldón, 2010). In Polytomella caeca, small organelles distinct from mitochondria were identified 362 that contained catalase activity (Gerhardt, 1971). Although previously typical peroxisomes could not be identified in *C. reinhardtii* (Silverberg, 1975), recently the β-oxidation enzyme acyl-CoA oxidase 363 364 as well as catalase were identified in peroxisomes (Kong et al., 2017; Kato et al., 2021). Also, the 365 enzymes of the glyoxylate cycle were shown in C. reinhardtii to localize to the peroxisome (or 366 glyoxysome) (Lauersen et al., 2016). The proposed butyrate metabolic network is depicted in Fig. 6 and 7. Its operation depends not only on the presence of the appropriate enzymes, but also on their 367 intracellular localization. Unfortunately, intracellular locales remain uncertain for some enzymes, due 368 369 to lack of experimental evidence, possible N-terminal truncation of the gene models and ambiguous or 370 obviously erroneous results from the prediction algorithms, which have not been trained specifically 371 for *Polytomella*. Still, for most of the highly butyrate-induced proteins, reasonable deductions could be 372 made that permit drawing a coherent picture of the intracellular location of the involved metabolic 373 pathways (Table I).

374

#### 375 **3.5.1 Peroxisomal butyrate assimilation pathway**

376 Once butyrate is taken up by the cell it must be activated to butyryl-CoA before it can enter the  $\beta$ -377 oxidation pathway in the peroxisome (Fig. 6). Candidates for this function were sought among the 378 proteins most highly induced by butyrate. The highest induction level (FC 0.002; see Table I for 379 Log2FC values) was found for g1889, which harbors at its C-terminus a typical PTS1 signal 380 (Neuberger et al, 2003). It was annotated by Mercator as long-chain acyl-CoA synthase/ligase 381 (LACS), an enzyme that does not act on fatty acids of less than 12 C-atoms (Wu et al., 2020). 382 However, different types of fatty acyl CoA synthases can be found to be more closely related to the 383 Polytomella enzyme using BLAST (45-50% ID), including medium chain acyl-CoA synthase and 384 even bacterial 3-methylmercaptopropionyl-CoA ligases. We thus changed the annotation of the 385 enzyme to fatty acyl-CoA synthase (FACS). This enzyme is the prime candidate for the production of 386 butyryl-CoA in *Polytomella* sp., pending further experimental confirmation. A true LACS isoenzyme 387 was also detected (UTR g2481, FC 0.16), but since its expression level is much lower than FACS, 388 this enzyme is unlikely to act as the first step of butyrate assimilation. Two acyl CoA oxidases 389 (ACX) were also highly butyrate-specific, with a FC value of 0.001 for ACX4 and 0.021 for its 390 paralog ACX. ACX4 was predicted to be localized in the plastid but homologs in other algae 391 including C. reinhardtii retrieved by BLAST searches (~51% ID) are annotated as peroxisomal 392 (Table I). Examination of the N-terminus of isoform ACX reveals a typical PTS2 signal and shows 393 34% sequence identity to C. reinhardtii ACX2, which catalyzes the first step of peroxisomal fatty 394 acid β-oxidation in the green alga *C. reinhardtii* (Kong et al. 2017). These two ACX enzymes likely 395 oxidize butyryl-CoA into crotonyl-CoA, which is converted into 3-hydroxybutyryl-CoA and then 396 into acetoacetyl-CoA by respectively the enoyl-CoA hydratase and the hydroxyacyl-CoA 397 dehydrogenase activities of the multifunctional protein MFP (Fig. 6). Compared to ACX4, MFP was 398 found to be more modestly induced by butyrate (FC 0.1). The final step of  $\beta$ -oxidation is carried out 399 by acetoacetyl-CoA thiolase (ATO1, FC 0.004), converting acetoacetyl-CoA into two molecules of 400 acetyl-CoA.

- 401 All 4 identified enzymes have typical PTS peroxisome targeting signals (Table I) and are thus
- 402 confirmed to be peroxisomally targeted. The fatty acid  $\beta$ -oxidation pathway used by *Polytomella* sp.
- 403 is typical for algae and plants, where it is found in both mitochondria and peroxisomes (Kong et al.,

404 2017; Li-Beisson et al., 2019; Pan et al., 2020; Kato et al., 2021).

- 405 We currently have no data on a mitochondrial  $\beta$ -oxidation pathway in *Polytomella* sp., but our study
- 406 clearly indicates that the peroxisomal pathway is key in the assimilation of butyrate. The peroxisomal
- 407 β-oxidation pathway of butyrate in *Polytomella* sp. differs from that in non-photosynthetic organisms
- 408 and bacteria by the CoA activation step and by the presence of MFP. Besides the use of a FACS type
- 409 enzyme, CoA activation of butyrate in mammals and microorganisms and can also use a butyrate-
- 410 CoA ligase/synthetase (EC 6.2.1.2) (De Preter et al., 2012). Conversely, fermentative butyrate
- 411 production from butyryl-CoA in bacteria mainly occurs via phosphate butyryltransferase (EC
- 412 2.3.1.19) + butyrate kinase (EC 2.7.2.7) (Walter et al., 1993) or butyryl-CoA:acetate CoA-transferase
- 413 (EC 2.8.3.8) (Duncan et al., 2002). The presence of a bifunctional MFP is the hallmark of
- 414 peroxisomal β-oxidation in plants, fungi and microalgae (Arent et al., 2010). In contrast, its two
- 415 reactions are carried out by separate enzymes in mitochondrial  $\beta$ -oxidation of butyrate in mammalian
- 416 colonocytes (De Preter et al., 2012).
- 417

#### 418 **3.5.2** Glyoxylate cycle and citrate/malate shuttles

419 The glyoxylate cycle comprises five enzymes which are mostly present in peroxisomes but some, 420 depending on the organism, can also be found in the cytosol, possibly to protect them from ROS-421 induced damage. In C. reinhardtii, the glyoxylate cycle allows growth on acetate (Lauersen et al., 422 2016) following its conversion into acetyl-CoA. Glyoxylate and acetyl-CoA are converted into 423 malate and further into citrate and succinate, which are exported to enter central carbon metabolism, 424 and can replenish the pool of TCA cycle intermediates. In *Polytomella*, the typical glyoxylate cycle 425 enzymes malate synthase (MAS1, FC 0.4) and isocitrate lyase (ICL1, FC 0.23) are induced on 426 butyrate, but at a lower level than citrate synthase (CIS2, FC 0.03) and malate dehydrogenase 427 (MDH2, FC 0.03) (Fig. 6). Aconitase (ACO) is also part of the cycle and three isoforms were 428 detected (suppl. Table I) but none were induced significantly by butyrate. MAS1 is confirmed to 429 localize in the peroxisome based on the presence of a typical PTS1 targeting signal at its C-terminus 430 (Gonzalez et al., 2011). CIS2 is predicted to be targeted to the peroxisome by DeepLoc (Almagro 431 Armenteros et al., 2017) (Table I) and its closest homologs are found in peroxisomes in plants and 432 yeast (Kunze et al., 2006; Rottensteiner and Theodoulou, 2006). Polytomella CIS2 and MDH2 show 433 highest amino acid sequence identities to peroxisomal/glyoxysomal-type homologs. ACO may also 434 be peroxisomal since three out of four amino acids of the consensus PTS2 signal are present (RV-X5-435 RA instead of RV-X5-H/QA) (Gonzalez et al., 2011). In C. reinhardtii, only ICL was found in the 436 cytosol with the other 4 enzymes in peroxisomal microbodies (Lauersen et al., 2016). Earlier it was 437 found that in Polytomella caeca, microbodies separated from mitochondria on a sucrose gradient 438 contained MAS and a minor part of ICL activity, with most of it being cytosolic (Haigh and Beevers, 439 1964). Since these authors concluded that the ICL activity within the microbodies accounted for the 440 observed acetate assimilation, it may be assumed that ICL functions in the peroxisome, as is also 441 predicted by DeepLoc (Table I). The upregulation of ICL1 on butyrate with respect to acetate may 442 indicate an increased activity of the cycle, resulting in higher glyoxylate and succinate production. 443 While glyoxylate serves to produce malate via MAS in the peroxisome, succinate may be exported to 444 the cytosol and further imported into the mitochondria for use in the TCA cycle (Fig 6). 445 The pronounced increase of MDH2 may be related to the production of NADH by MFP during 446 butyrate  $\beta$ -oxidation in the peroxisome. At the expense of NADH, MDH2 can convert oxaloacetate 447 (OAA) into malate, which can be later exported to the cytosol (Fig. 6) via a malate/OAA transporter

448 (Rottensteiner and Theodoulou, 2006). Export of citrate produced by CIS2 from oxaloacetate is 449 likely occurring under butyrate growth considering the very strong induction of the cytosolic 450 ATP:citrate lyase (ACLY, FC 0.005). This enzyme produces acetyl-CoA and oxaloacetate from citrate in the cytosol, thus allowing the export of acetyl-CoA. The oxaloacetate resulting from ACLY 451 452 can be re-imported to replenish the peroxisomal oxaloacetate pool for the proper functioning of the 453 glyoxylate cycle (Fig. 6). Despite the significant relatedness of MDH2 to its peroxisomal homolog in 454 C. reinhardtii, (62% amino acid identity) it can currently not be excluded that MDH2 is cytosolic, 455 and if so, this would indicate an increased need for malate/oxaloacetate shuttle activity to sustain 456 increased production and export of citrate from the peroxisome. A cytosolic localization for MDH, 457 ACO and ICL occurs in yeast and does not impact glyoxylate cycle function (Rottensteiner and 458 Theodoulou, 2006). The fact that MDH2 and CIS2 are more induced than ICL1 and MAS1 points to 459 an apparent increased need for a malate/oxaloacetate shuttle and citrate export in butyrate 460 metabolism. With regard to CIS, it was shown that during  ${}^{14}$ C-acetate assimilation of *P. caeca*, malate was by far the most important immediate product incorporating <sup>14</sup>C, with succinate and 461 462 (mitochondrial) fumarate 10-fold lower, but hardly any citrate was formed (Haigh and Beevers, 463 1964). Conversely, judged from the upregulation of CIS2 and ACLY, butyrate seems to specifically induce peroxisomal citrate production. Since the outcome of butyrate utilization is the increased 464 465 production of acetyl-CoA in the cytosol from ACLY, an induction of fatty acid synthesis may be 466 expected in organelles. It is interesting that in human colonocytes, butyrate stimulates cell 467 proliferation via histone acetylation in the nucleus, involving the production of acetyl-CoA by ACLY (Donohoe et al., 2012). In our study, no histone acetyltransferase was found differentially expressed. 468

469

#### 470 **3.5.3 Transporters and metabolite exchange**

471 Relative to acetate, butyrate induced 10 membrane bound transporter proteins with significant 472 associated FC values (Table I, category "solute transport"), among which genuine peroxisomal 473 transporters. However, the identity of the proteins transporting butyrate or butyryl-CoA into the 474 peroxisomes remains uncertain. The ABCD transporter PXA (FC 0.1) shows high similarity to an 475 ABCD transporter in C. reinhardtii (A0A2K3CWL4/Cre15.g637761) which was confirmed to be 476 involved in the import of activated long-chain fatty acids from the cytosol to the peroxisomal matrix, 477 similar to the yeast peroxisomal ABC transporters PXA1 and PXA2 (Hettema et al., 1996). PXA 478 targets long-chain fatty acyl-CoA molecules, which butyryl-CoA is not, so its involvement in the 479 import of butyryl-CoA from the cytosol is uncertain. It might be necessary instead to channel CoA 480 into the peroxisome for CoA homeostasis. Potentially, the two cytosolic acetyl-CoA synthase-type 481 enzymes (ACSS) that were upregulated by butyrate (FC 0.08, 0.11) may provide substrates for this 482 process. Another induced transporter belongs to the PEX11 family (FC 0.09, category cell cycle in 483 Table I), a membrane protein that promotes peroxisome division in eukaryotes and is crucial for 484 medium-chain fatty acid (MCFA) beta-oxidation. It was proposed that in yeast, PEX11 provides 485 MCFAs including butyrate to the peroxisome interior for CoA activation, effectively fulfilling a 486 transporter function (van Roermund et al., 2000). Two further proteins show clear homology to the 487 peroxisomal NAD carrier PXN (FC 0.155, 0.231) in Arabidopsis thaliana, which mediate the import 488 of NAD into peroxisomes against AMP (van Roermund et al., 2016). PXN belongs to the 489 mitochondrial carrier (TC 2.A.29) family, which contains also peroxisomal transporters. Butyrate 490 may thus increase the import of cofactors in the peroxisome, possibly linked to enhanced peroxisome 491 biogenesis. 492 Three proteins were identified as mitochondrial transporters, indicating also an involvement of

493 mitochondrial metabolism in butyrate utilization. Two of them are subunits of the mitochondrial

494 pyruvate transporter (MPC1, FC 0.08 & MPC2, FC 0.1), an oligomeric complex of approximately

495 150 kDa in the inner mitochondrial membrane which constitute the sole entry point into the

- 496 mitochondria of pyruvate, produced by glycolysis or from malate. The upregulation of this carrier is
- 497 of fundamental importance in establishing the metabolic programming of a cell (Bricker et al., 2012).
- 498 Once in the matrix, pyruvate can be converted into acetyl-CoA by the pyruvate dehydrogenase
- 499 complex (PDH) and feed the TCA cycle (McCommis and Finck, 2015). Cycle turnover produces
- $CO_2$  and reducing power further used for ATP production, but intermediates can be siphoned off such
- 501 as citrate, which can exit the mitochondria and be cleaved back to acetyl-CoA and oxaloacetate by 502 ATP citrate lyase (ACLY) in the cytosol. Another transporter identified is homologous to the
- 502 ATF chrate types (ACLT) in the cytosol. Another transporter Identified is nonlologous to the 503 mitochondrial dicarboxylate/tricarboxylate transporter DTC (FC 0.6) in *A. thaliana* (Millar and
- 504 Heazlewood, 2003). DTCs transport dicarboxylic acids (eg malate, oxaloacetate) and tricarboxylic
- acids (eg citrate, isocitrate) into the mitochondrial matrix. In view of the FC value of 0.6, the role of
- 506 DTC is only modestly increased in butyrate metabolism, but the iBAQ value for DTC is highest
- among transporters and represents one of the most abundant among butyrate induced proteins,
- 508 illustrating the importance of di/tricarboxylates for mitochondrial metabolism. Seeing that the levels
- 509 of the proteins of mitochondrial respiration (OXPHOS complexes) are not induced by butyrate, it can 510 be proposed that increased import of pyruvate and dicarboxylates feeds other metabolic pathways,
- 510 be proposed that increased import of pyruvate and dicarboxyrates reeds of 511 such as amino acid synthesis (see below).
- 512 Furthermore, two general substrate transporters of the Major Facilitator Superfamily were identified
- 513 (MFS, FC 0.2, 0.56). MFS transporters can only transport small solutes in response to chemiosmotic
- 514 ion gradients and can be found anywhere in the cell, so their proposed placement in the peroxisomal
- 515 membrane for transport of carboxylates is speculative (Fig 6). The monocarboxylate transporters
- 516 MCT that are known in humans to transport acetate and butyrate across the plasma membrane are
- also members of the MFS family (Casal and Leão, 1995), but they are not orthologous to the two
- 518 MFS proteins mentioned above. Also, a typical MCT could not be found in the *Polytomella* sp.
- 519 genome. However, a member of the formate/nitrite transporter (TC 2.A.44) family (FNT, FC 0.21)
- 520 was found to be induced by butyrate. FNT transporters transport monovalent anions and are not 521 strictly selective as they can use nitrite or formate but also larger organic anions such as lactate and
- 521 strictly selective as they can use nitrite or formate but also larger organic anions such as lactate and 522 acetate (Lu et al., 2012). It may thus be that this FNT is actually responsible for butyrate transport
- 523 over the plasma membrane in *Polytomella* sp. Further biochemical and genetic studies need to
- 524 confirm whether this is the case. Five genes belonging to the GPR1/FUN34/YaaH (GFY)
- 525 superfamily and homologous to bacterial acetate/succinate channels were found to be induced by
- 526 acetate in *C. reinhardtii* and possibly implicated in intracellular acetate transport (Durante et al.,
- 527 2019). In the *Polytomella* sp. genome, 4 GFY genes were identified of which only 1 (UTR\_1663.t1)
- 528 was found in the proteome induced by butyrate at FC 0.636 (but with p>0.004).
- 529 One transport protein is actually slightly downregulated, a P-type plasma membrane H+-ATPase
- 530 (PMA3, FC 3.9) that exports cellular protons (Morth et al., 2011). In C. reinhardtii, increased PMA
- 531 expression was found to improve tolerance to high CO<sub>2</sub> concentrations, which are toxic due to the
- 532 acidification of the cell interior (Choi et al., 2021). Acetate or butyrate are imported in the protonated
- form and dissociate in the cytosol. It can be hypothesized that butyrate necessitates less expulsion of
- 534 H<sup>+</sup> since it contains relatively fewer carboxylic acid groups at only 1 COOH per 4 C-atoms while
- 535 acetate contains 1 COOH per 2 C-atoms.
- 536

#### 537 3.5.4 Antioxidant defense

- 538 Reactive oxygen species (ROS) are important in cellular signaling, but stress conditions may cause
- 539 increased ROS production and result in oxidative damage (Rezayian et al., 2019). Various
- 540 antioxidant defense systems to neutralize ROS exist in different cellular compartments, especially in
- 541 organelles that are major sources of ROS such as H<sub>2</sub>O<sub>2</sub> (Roy et al., 2021). The butyrate metabolic

542 responses include a total of 10 proteins that are associated to antioxidant defense. One catalase 543 isoform, co-orthologous to the C. reinhardtii CAT1 isoform that localizes to peroxisomes (Kato et 544 al., 2021) and similarly endowed with a non-canonical C-terminal PTS1 signal (SVL), was found 545 markedly induced on butyrate (FC 0.003), while a second CAT1 ortholog was far less induced. No 546 clear ortholog was found for the C. reinhardtii ER-localized CAT2. Catalase upregulation probably 547 relates to the  $\beta$ -oxidation of butyrate, where it allows the detoxification of H<sub>2</sub>O<sub>2</sub> produced by ACX 548 into H<sub>2</sub>O and O<sub>2</sub>. Using density gradients, (Gerhardt, 1971) found the catalase and malate synthase 549 activities in different particulate fractions in *P. caeca*, which raised the question whether different 550 types of peroxisomes exist in the cell. A study to detect peroxisomes using CAT-specific staining 551 seemed to shown that indeed different staining intensities existed in a sample of isolated peroxisomes 552 (Gerhardt and Berger, 1971). 553 Ascorbate peroxidase (APX, FC 0.015) was highly induced by butyrate. It is part of the glutathione-554 ascorbate cycle (GAC) that uses electrons from NAD(P)H for the reduction of H<sub>2</sub>O<sub>2</sub> to H<sub>2</sub>O. Other 555 GAC enzymes were also induced on butyrate, such as glutathione S-transferase (GST3, FC 0.51), 556 while glutathione reductase (GR) was not. The GAC can be found in different cellular compartments 557 such as plastids, mitochondria, peroxisomes and the cytosol, (Caverzan et al., 2012). Since no 558 coherent targeting signals were found for *Polytomella* APX, GST3 and GR, the GAC was tentatively 559 placed in the cytosol in Fig. 6 since the closest homologs of these enzymes in C. reinhardtii are 560 predicted to be cytosolic. A typical 2-Cys peroxiredoxin (PRX2, FC 0.05) was found highly induced 561 on butyrate. PRXs are important for cellular redox signaling and antioxidant defense as they detoxify 562 organic hydroperoxides (R-O-OH) that can be formed from the reaction of organic molecules with 563 H<sub>2</sub>O<sub>2</sub> (Liebthal et al., 2018). Another important ROS scavenging enzyme is superoxide dismutase, 564 which produces  $H_2O_2$  from  $O_2^-$ . Two SOD isoforms were found, only modestly induced on butyrate 565 (MSD1, FSD1, FC 0.26, 0.34). The localization of PRX2 and M/FSD1 is uncertain as they lack 566 typical targeting signal and were predicted to be cytosolic by DeepLoc. Intriguingly, the levels of 567 plastid type alternative oxidase (PTOX, FC 0.43), which functions in plastid redox homeostasis by 568 oxidizing plastoquinol to reduce O<sub>2</sub> to H<sub>2</sub>O in photosynthetic organisms (Krieger-Liszkay and Feilke, 569 2016), and the NAD(P)H dehydrogenase that feeds electrons into the plastoquinone pool (NDA2, FC 570 0.15), were higher on butyrate than acetate. This suggests a role of chlororespiration in antioxidant 571 defense in *Polytomella*. It is of note that these enzymes are found in the thylakoid membrane in C. 572 reinhardtii, while in Polytomella sp. a localization to the amyloplast envelope is proposed in absence 573 of a description of any intraplastidial membrane system (Fuentes-Ramírez et al., 2021). 574 Interestingly, photosynthesis in rice leaves was found to be protected due to a more efficient 575 antioxidant response when CAT and APX activity were limited, which was proposed to be because 576 of higher  $H_2O_2$  levels that exert a positive regulatory influence (Sousa et al., 2019). First off, it would 577 be interesting to know whether the C4 fatty acid butyrate does in fact induce  $\beta$ -oxidation in 578 photosynthetic algae since it is known that *C. reinhardtii* favors membrane turnover over β-oxidation 579 in presence of exogenous C16 fatty acid (Kato et al., 2021). If not it would explain directly why 580 butyrate is poorly used by *C. reinhardtii* (Lacroux et al., 2020). If butyrate does enter β-oxidation, 581 increased CAT and APX could modify ROS levels and, in the view of (Sousa et al., 2019), interfere 582 with photosynthesis and hinder the growth on butyrate by green algae, as observed by (Lacroux et al., 583 2020). Polytomella sp does not perform photosynthesis and is thus less affected by the very strong 584 antioxidant responses elicited by that the  $\beta$ -oxidation of butyrate, which is possibly at the basis of its 585 capacity to grow well on butyrate. 586

#### 587 3.5.5 Branched chain amino acid degradation

588 A number of proteins induced on butyrate, placed in both the lipid and amino acid metabolism 589 categories (Table I), potentially participate in the degradation of branched chain amino acids 590 (BCAAs), by which value is converted to propionyl-CoA, while degradation of isoleucine produces 591 both propionyl-CoA and acetyl-CoA (Fig. 7). This BCAA pathway is described in prokaryotes and in 592 eukaryotes such as mammals, yeasts and plants (Binder, 2010), but also in microalgae, for example 593 the diatom *Phaeodactylum tricornutum* (Pan et al., 2017) or *C. reinhardtii* (Liang et al., 2019). The 594 first enzyme of this pathway is branched-chain aminotransferase (BCA2, FC 0.28), probably located 595 in the mitochondria. Except for the second enzyme, branched-chain alpha-keto acid dehydrogenase 596 (BCKDC, FC 2.1), all enzymes in this pathway are induced by butyrate, in particular the central 597 enzyme methylmalonate semialdehyde dehydrogenase (MMSA, FC 0.005). Most of the dowsntream 598 enzymes seem to be targeted to the peroxisome in Polytomella sp. (Table I), recapitulating the 599 situation in plants where BCAA degradation starts in the mitochondrion to yield CoA-esterified 600 metabolites that are further converted in the peroxisome (Linka and Theodoulou, 2013). 601 Questions remain about this pathway in *Polytomella* sp. The pathway depends likely on the cellular 602 localization of MMSA. While the C. reinhardtii methylmalonate semialdehyde dehydrogenase 603 (ALDH6) is predicted to be mitochondrial, the *Polytomella* ortholog is predicted to be peroxisomal 604 (Fig. 7). If the latter is the case, the degradation of both isoleucine and valine towards acetyl-CoA can 605 occur unimpeded in the peroxisome. If we however entertain the possibility that MMSA is 606 mitochondrial in *Polytomella* sp., the situation is different. MMSA is able to convert MMS into 607 propionyl-CoA but also malonate semialdehyde (MS) into acetyl-CoA, so the degradation of 608 isoleucine into MS (via propionyl-CoA) does not demand the presence of MMSA in the peroxisome 609 when MS is imported into mitochondria. Mitochondrial MMSA can convert MS into acetyl-CoA 610 which can be further utilized without problems. In the case of valine degradation, the absence of 611 MMSA in the peroxisome would block the pathway at the level of the conversion of MMSA to 612 propionyl-CoA, and in that case MMS would have to be exported to the mitochondria. Here, MMSA 613 would convert MMS into propionyl-CoA, but its fate in the mitochondria would not be obvious: the 614 enzymes necessary for its conversion to succinyl-CoA (propionyl-CoA carboxylase producing (S)-615 methylmalonate-CoA, methylmalonyl-CoA epimerase producing (R)-methylmalonate-CoA and 616 methylmalonyl-CoA mutase to convert it to succinyl-CoA) could not be identified in the *Polytomella* 617 genome. This is similar to the case of P. tricornutum where the epimerase step was not detected (Pan 618 et al., 2017). In *P. caeca* cells grown on propionate, propionyl-CoA carboxylase activity could not be 619 detected (Lloyd et al., 1968). The same is true in plants, unlike in mammals and bacteria (Linka and 620 Theodoulou, 2013). The TCA cycle enzyme succinyl-CoA ligase (SCL, FC 0.77 at p>0.003), 621 somewhat induced by butyrate, was found to be a promiscuous enzyme that produces also thioesters of malate, fumarate and glutarate among others (Nolte et al., 2014). It may be hypothesized that SCL 622 623 can produce succinyl-CoA directly from methylmalonate semialdehyde (MMS). Alternatively, MMS 624 may also be imported into mitochondria and converted into malonate by an aldehyde dehydrogenase 625 (ALD5 EC:1.2.1.-; at least 5 enzymes are found in the proteome, suppl. Table I) and then further into 626 malonyl-CoA via malonate ligase (ACSF3, FC 0.38 but with p>0.004), which serves as precursor for 627 fatty acid synthesis (see 3.5.6). It is noted that even if ALD5/ACSF3 are not located in the 628 mitochondria, the products can be imported into the organelle. Alternatively, the BCAA degradation 629 pathway may be streamlined when MMSA is dually targeted to both peroxisome and mitochondria, 630 which is known for other enzymes such as CAT (Petrova et al., 2004). 631 In the non-sulfur purple bacterium *Rhodospirillum rubrum*, which does not possess a glyoxylate 632 cycle, the BCAA degradation pathway was identified as assimilatory during growth on butyrate (De 633 Meur et al., 2020). Interestingly, R. rubrum grew 3-fold faster in presence of HCO<sub>3</sub><sup>-</sup>, which serves as

634 electron sink and helps antioxidant defense. However, since *Polytomella* sp. does possess an active

635 glyoxylate cycle, the purpose of the BCAA degradation pathway in butyrate assimilation is not

- directly obvious. It could serve to produce propionyl-CoA for metabolic pathways such as the
- 637 synthesis of coenzyme A. Leucine degradation has been found in *A. thaliana* alongside starch and
   638 lipid degradation in response to stress conditions that perturb cellular energy balance, such as
- senescence and carbon deprivation (Mentzen et al., 2008). In these conditions, it is conceivable that
- 640 the cell makes up for a lack of energy and carbon by mobilizing internal reservoirs of sugar, lipid and
- 641 amino acids. In *Polytomella*, all three are observed in cells growing on butyrate (see 3.5.6), whereby
- 642 sugars and lipids may serve to produce amino acids such as BCAAs. We propose that butyrate is
- 643 metabolized and yields acetyl-CoA and further di/tricarboxylic acids at a slower rate than acetate,
- 644 which is compensated for by the degradation of BCAAs to produce acetyl-CoA and possibly
- 645 succinyl-CoA that feed into carbon metabolism. A factor in the induction of the BCAA degradation
- 646 pathway specifically may be the fact that it shares several enzymes with the  $\beta$ -oxidation of butyrate
- 647 (ACX, MFP, ATO).
- 648

#### 649 **3.5.6 Catabolic production and role of pyruvate**

Pyruvate is at the crossroads of many metabolic pathways and is important in all cells and cell 650 651 compartments (Shtaida et al., 2015). There are multiple indications that butyrate metabolism goes 652 also through pyruvate, while it is not predicted to be directly involved in acetate utilization. First, most enzymes of glycolysis are upregulated several fold under butyrate, including pyruvate kinase 653 654 (PYK1, FC 0.13) (Table I), which should result in increased pyruvate production and ATP. 655 Compared to acetate, the balance seems to be shifted towards starch and glucose degradation, in line with the cellular sugar content being lower on butyrate (Fig. 1D) and the induction of the 656 657 mitochondrial MPC transporter for pyruvate (see 3.5.3). This may not be leading to higher TCA 658 cycle and OXPHOS activities since the necessary proteins are not induced, but pyruvate may instead 659 be converted into amino acids such as alanine, and fatty acids (see below). Also, pyruvate 660 decarboxylase (PDC3, FC 0.14) was induced, which should lead to acetaldehyde production in the 661 cytosol. This could diffuse through the mitochondrial membrane and then be converted into acetate 662 by NAD+ aldehyde dehydrogenase (ALD5, FC 0.03) and then acetyl-CoA by acetyl-CoA synthase 663 (ACSS, FC 0.01). This scenario is supported by the fact that *Polytomella caeca* can grow on 664 acetaldehyde (1mM) as sole external carbon source (Wise, 1968). It cannot be excluded that acetaldehyde is converted into acetate in the cytosol which is then imported into the mitochondria 665 666 (see 3.5.8). Finally, there may also be a contribution from NADP malic enzyme (ME, FC 0.82 with p>0.004) converting malate to pyruvate in the cytosol. Since this enzyme was predicted to be 667 668 targeted to the plastid, it can provide a source of pyruvate from imported malate. Via an MDH type 669 enzyme (5 different MDH were detected in the proteome, suppl. Table I) in the plastid that produces 670 NADH, malate may also feed the PTOX enzyme that was found induced on butyrate (see 3.5.4) and 671 is implicated in maintaining cellular redox balance. Indeed, 2 MDH enzymes and PTOX were 672 detected in a proteomics study of isolated non photosynthetic plastids from Polytomella parva 673 (Fuentes-Ramírez et al., 2021). Pyruvate is also at the basis for the production of coenzyme A and 674 NAD+, with pantoate:beta-alanine ligase (PANC, FC 0.21) of the CoA/ACP synthesis pathway and 675 quinolinate synthase (QS, FC 0.62) of the NAD+ synthesis increased, suggesting a need of CoA/ACP 676 in butyrate metabolism. A clear upregulation is found of two of the four enzymes of the type II fatty acid synthesis (FAS) 677 678 system, which uses an acyl carrier protein (ACP): 3-oxoacyl-ACP reductase (fabG, FC 0.006) and

- 679 enoyl-ACP reductase (MECR, FC 0.184). In *C. reinhardtii*, the four different subunits of the type II
- 680 FAS system are predicted to be dually targeted to the mitochondrion and chloroplast, similar to
- plants (Riekhof et al., 2005; Li-Beisson et al., 2013). Fatty acids produced in the plastid are used for

682 the production of membranes, storage and signaling lipids (Li-Beisson et al., 2015). The FAs are unlikely to be destined for the production of storage lipids since levels are actually lower in butyrate 683 684 grown cells (Fig. 1D). Fatty acids produced by mitochondrial (mt)FAS play various roles. The mtFAS pathway fuels the production of acyl-ACPs including octanoyl-ACP, which is a precursor of 685 lipoic acid, a cofactor of several metabolic enzymes: pyruvate dehydrogenase (PDH), a-ketoglutarate 686 dehydrogenase (KGDH), branched-chain α-ketoacid dehydrogenase (BCKDH), the glvcine 687 688 decarboxylase complex (GDC), and plastidial pyruvate dehydrogenase (ptPDH) (Guan et al., 2020). 689 Four out of five of these enzymes are indeed upregulated on butyrate with FC values of 0.58-0.87, 690 and although these values are not statistically sound enough to warrant inclusion in Table I, it does 691 represents a clear trend. Paradoxically, the only enzyme not changed is BCKDH, which is involved 692 in the BCAA degradation pathway that is highly expressed on butyrate. This suggests that the 693 pathway is not regulated at the level of this enzyme, which is not an uncommon observation in 694 biochemical studies (eg Nogaj et al., 2005). The mtFAS system is possibly induced to provide acyl-695 ACPs to two enzymes involved in biotin synthesis, 3-oxoacyl-ACP reductase (OAR, FC 0.06 and 7keto-8-aminopelargonic acid synthase (KAPAS, FC 0.016), which uses pimeloyl-ACP as substrate. 696 697 Biotin is known to be a cofactor of certain carboxylase enzymes, including acetyl-CoA carboxylase 698 (ACC) which functions 2 steps upstream of the FAS system producing malonyl-CoA from acetyl-699 CoA. ACC was the only enzyme with a biotin cofactor that was detected in the Polytomella 700 proteome, and although it is not induced by butyrate it may be regulated post-translationally. It is 701 noted that ACLY in the cytosol is strongly induced (see 3.5.2) and produces the acetyl-CoA that is a 702 direct substrate for ACC. Biotin has been described to exert regulatory influences in cell signaling, 703 for example the upregulation of glucose metabolism (Dakshinamurti, 2005), which was indeed 704 induced on butyrate.

705

#### 706 **3.5.7 Metabolic activities on acetate**

707 The differential approach revealed that the proteins more abundant on acetate than on butyrate tend to 708 relate to the protein biosynthesis and homeostasis (further referred to as proteostasis) rather than to 709 specific metabolic pathways. Among the over-represented categories are "RNA processing" and 710 "Protein biosynthesis, modification and homeostasis". This includes heat-shock proteins, protein 711 kinases, maturation-, elongation- and assembly factors. Although butyrate induced more proteins 712 compared to acetate, there may also be downregulation signals produced in response to specific 713 metabolic needs imposed by butyrate. A specific perception of an acetate-linked metabolite and 714 associated signal cascades may also be involved. Some of the proteins suppressed by butyrate may 715 suggest the implication of a mitogen-activated protein kinase (MAPKs) signal transduction pathway, 716 which modulates important cellular processes such as proliferation, stress responses, apoptosis and 717 immune defense via consecutive protein phosphorylations by serine and threonine protein kinases 718 (Soares-Silva et al., 2016). 719 We note the induction of a protein of uncertain function, being either protein kinase (MAP3K-RAF) 720 or dual specificity kinase splA isoform B (FC 4.663). It may suggest activation of a signal 721 transduction pathway for positive regulation of gene transcription from a receptor on the cell surface 722 (Soares-Silva et al., 2016). The presence of a PPP Fe-Zn-dependent phosphatase (FC 1.8) involved in

- reversible protein posttranslational modification points also in this direction. Cytosolic Hsp70
- chaperone (FC 12.422) may also be involved in this MAPK signaling pathway, as is the case in
- mammals (Fan et al., 2018). GTPase activating component Ran-GAP (FC 2.862) is also known to be
- implicated downstream of MAPK responses (Faustino et al., 2007). A number of proteins involved in
- different stages of synthesis and maturation of RNAs and proteins are found. This includes the
- mitochondrial Tr-type G domain-containing GTPase/elongation factor Tu (FC 8.245) which bring the

729 aminoacyl-tRNA into the A site of the mitoribosome, and Nsa1/WDR74 (FC 3.966), an assembly

- 730 factor involved in the maturation of the large subunit of the cytosolic ribosome. The only ribosomal
- 731 protein that is overaccumulated is RPL38, suggesting that it performs an additional function. Several
- 732 proteins involved in the biogenesis and maturation of mRNA and ribosomes are found at FC values
- 733 of 2-3, which are at the 'executive' side of signal transduction pathways that end in protein synthesis
- 734 (Table I).
- 735 Of note are the three plastidial small heat shock proteins (HSP20, FC 12.510, 10.588, 6.530) for
- 736 which little data exist in microalgae but in plants play a central role in the protection against stress
- 737 damage, in the folding, intracellular distribution, and degradation of proteins, as well as in signal
- 738 transduction chains (Ouyang et al., 2009). The HSPs are known to be generally involved in the
- 739 response to stress most notably due to heat, but also other stresses that can affect protein stability 740 such as oxidative stress, salinity or pH (Strauch and Haslbeck, 2016). Acetate is more likely than
- 741 butyrate to be transported across the cell and imported into organelles to give rise to acetyl-CoA and
- 742 further biosynthesis reactions (Boyle et al., 2017). Butyrate is likely only taken up in the peroxisome
- 743 and di/tricarboxylates are exported into the cytoplasm and further into organelles. Since acetate is
- 744 transported in the protonated form it will systematically release H+ within the organelles, which may 745 cause some level of stress and possibly explain the increased need for HSP20.
- 746 The mitochondrial organization/maturation factor (CHCH domain) (FC 16.131) is the most induced
- 747
- protein compared to butyrate. Its function is uncertain, but may relate to protein translation or post-748 translational maturation of cytochrome c oxidase. Finally, although most enzymes involved in amino
- 749 acid synthesis were mildly induced by butyrate, a few enzymes involved in production of aromatic
- 750 amino acids and methionine were more abundant on acetate (FC ~2.5). Methionine is a direct
- 751 precursor of S-adenosylmethionine (SAM), an important posttranslational regulator of many cellular
- 752 processes, including autophagy, the recycling of cellular components in response to stress (Ouyang et
- 753 al., 2020). Butyrate induction of proteins such as the stress-induced carboxypeptidase (SCPL, FC
- 754 0.47) (Xu et al., 2021) and universal stress protein (IMP2, FC 0.34) seem to indicate that butyrate
- 755 indeed causes some level of stress to the cells. It may thus be hypothesized that butyrate causes a
- 756 decrease methionine to lower SAM, since it inhibits processes involved in stress response such as 757 autophagy.
- 758

#### 759 4 **Conclusions and perspectives**

760 The key hypotheses that have been proposed in the past concerning limitations in the trophic

- 761 metabolism of microalgae relate to cell permeability, toxic products formed from the substrate, lack
- of enzymes necessary for effective dissimilation of the substrate or their improper cellular location, 762
- 763 lack of transcriptional control, effect of low-intensity light in stimulating heterotrophic growth and
- 764 respiratory deficiency, etc. (Neilson and Lewin, 1974). In this work, these key hypotheses were
- 765 considered with regard to butyrate assimilation in *Polytomella* sp., and the relation with butyrate
- 766 metabolism in other organisms is discussed as well as the potential implications of these findings for
- 767 the capacities for butyrate assimilation of other -green- algae. In addition, a major step has been made
- 768 in our understanding of peroxisomes in *Polytomella* sp. and in relation to its close relative C. 769 reinhardtii.
- 770 Based on our data, we propose that butyrate is assimilated via peroxisomal  $\beta$ -oxidation resulting in
- 771 acetyl-CoA and di/tricarboxylates for cellular use via the glyoxylate cycle. We found that multiple
- 772 transporters are induced to facilitate the metabolic interplay between peroxisome and other cell
- 773 compartments. Although no monocarboxylate transporter was identified for butyrate transport, a
- 774 formate/nitrite transporter was put forward as candidate for this function. We hypothesize that
- 775 butyrate causes a major antioxidant defense response related to the production of  $H_2O_2$  and NADH in

- 776 β-oxidation. An increased turnover of BCAAs to propionyl-CoA and acetyl-CoA was suggested,
- which may, together with an overproduction of pyruvate from glycolysis, serve amino acid or
- cofactor production. Butyrate lowers accumulation of carbohydrates and lipids while fatty acid
- synthesis was found induced, probably in the mitochondria. This all may serve organellar
- reorganization (peroxisomes) and the production of cofactors for several central metabolic enzymes
- to accommodate butyrate utilization. In contrast, acetate utilization seems to stimulate activities that
- relate to the biosynthesis and homeostasis of proteins.
- 783 Its fast butyrate assimilation makes *Polytomella* sp. a good model for the study of VFA metabolism,
- but the high starch levels even during the exponential growth is another distinctive trait that allow
- continuous cultivation on dark fermentation effluents with potential for biofuel production. Our
   proteomics approach revealed in many instances the induction on butyrate of multiple proteins
- 786 proteomics approach revealed in many instances the induction on butyrate of multiple proteins 787 belonging to the same pathway or similar metabolic activities suggest their importance in butyrate
- metabolism. Other omics and biochemical approaches should be employed to further explore the
- specificities of butyrate vs acetate as a carbon source. In particular, metabolomics and fluxomics
- should be used to reveal the assimilation pathways. The main issues that remain to be tackled relate
- 791 to the import of VFAs into the cell and the role of  $\beta$ -oxidation and associated antioxidant activities,
- especially in green algae. As a non-photosynthetic alga, *Polytomella* can serve as a metabolic
- reference for efficient butyrate assimilation, to which other (green) algae may be compared. Since
- Polytomella sp. does not seem to appear to possess novel metabolic capacities *per se*, it should be
- considered that this alga owes its fast butyrate assimilation in some way to the loss of another major
- 796 metabolic capacity: photosynthesis.
- 797

#### 798 **5 Tables**

- 799 **Table I.** Overview of the most pertinent proteins with significant FoldChange values arranged by
- 800 metabolic category as determined by Mercator. PTS, presence of peroxisome targeting signal;
- 801 Loc\_Chlre, location (when discordant) and accession no. of *C. reinhardtii* ortholog. Proteins
- 802 corresponding to the E-values are given in the suppl. Table I.

#### 804 6 Conflict of Interest

805 The authors declare that the research was conducted in the absence of any commercial or financial 806 relationships that could be construed as a potential conflict of interest.

#### 807 **7** Author Contributions

808 JL performed experiments, data acquisition, data curation, formal analysis and writing of the original

809 draft. AA contributed to conceptualization, experiments, data acquisition, data curation, formal

analysis, validation, review and editing of the original draft. SB performed experiments, data

811 acquisition, data curation and formal analysis. YC performed data acquisition, data curation, formal

812 analysis, validation, review and editing of the original draft. OV performed data acquisition, data

curation, formal analysis, validation, review and editing of the original draft. JPS contributed to
 supervision, funding acquisition, validation, review and editing of the original draft. RVL designed

original experimental plan and performed experiments, data acquisition, data curation, formal

- analysis, supervision, funding acquisition, validation, review and editing of the original draft. All
- 817 authors approved the final version of the manuscript.

#### 818 **8 Funding**

819 JL received a PhD fellowship from European Union from the Occitanie region, France, with

820 complementary funding from FEDER. This study was funded by the National Institute of

Agriculture, Alimentation and Environment (INRAE), the CNRS, and was supported by the

822 FermALip project, funded by the Carnot institute 3BCAR as well as by the "Initiative d'Excellence"

program from the French State (Grant 'DYNAMO', ANR-11-LABX-0011-01). The proteomic

824 experiments were partially supported by Agence Nationale de la Recherche under projects ProFI

825 (Proteomics French Infrastructure, ANR-10-INBS-08) and by GRAL, a program from the Chemistry

826 Biology Health (CBH) Graduate School of University Grenoble Alpes (ANR-17-EURE-0003).

#### 1153 10 Supplementary Material

1154 Supplementary Table I. Differential analysis of total proteomes from *Polytomella* sp. grown on 1155 acetate or butyrate.

#### 1156 **11 Data Availability Statement**

- 1157 The mass spectrometry proteomics data have been deposited to the ProteomeXchange Consortium
- via the PRIDE partner repository with the dataset identifier PXD035155
- 1159 (<u>https://www.ebi.ac.uk/pride/login</u>)
- 1160
- 1161 **12 Figures**

(which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is m available under aCC-BY-NC-ND 4.0 International license.

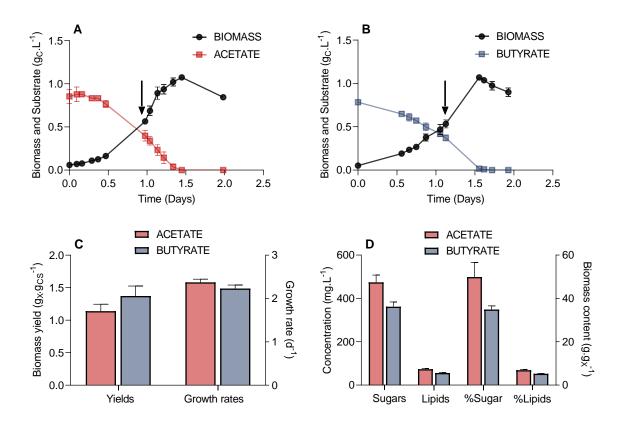

Figure 1. Parameters of the growth of Polytomella sp. on acetate and butyrate. A,B) Growth curves  $(g_X.L^{-1})$  and substrate consumption  $(g_{CS}.L^{-1})$  of Polytomella sp. in presence of  $1 g_{CS}.L^{-1}$  acetate or butyrate, C) biomass yields  $(g_X.g_{CS}^{-1})$  and growth rates  $(d^{-1})$  derived from these growth curves and D) the concentrations of sugars and lipids are plotted on the left  $(g.L^{-1})$  while their proportions to the total biomass are plotted on the right  $(g.g_X^{-1})$  for both conditions. Arrows indicate when biomass for further proteomics analysis was sampled. X, dry weight; CS, dissolved organic carbon. Error bars correspond to standard deviations based on 3 biological replicates.

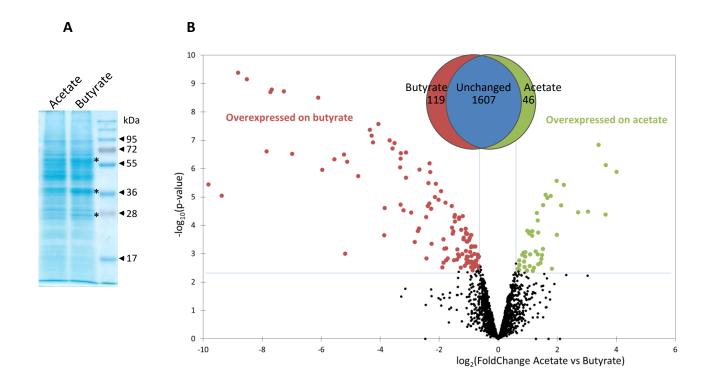

Figure 2. Comparison of global proteomes of *Polytomella* sp. grown on acetate and butyrate. A) Total proteins (30 µg) of *Polytomella* sp. growing exponentially on acetate or butyrate, resolved in a 12% SDS-polyacrylamide gel stained with Coomassie Blue G250. B) Volcano plot displaying the differential abundance of proteins of *Polytomella* sp. grown on acetate or butyrate analysed by MS-based quantitative proteomics. The volcano plot represents the -log10(limma p-value, cut off 0.004) on y-axis plotted against the log2(FoldChange acetate/butyrate) on the x-axis. Green and red dots represent proteins found more abundant in *Polytomella* sp. grown respectively on acetate or butyrate (Benjamini-Hochberg FDR < 1%). The Venn diagram indicates that of the total of 1772 proteins detected for acetate and butyrate combined, 48 were significantly induced on acetate and 117 on butyrate.a

A)

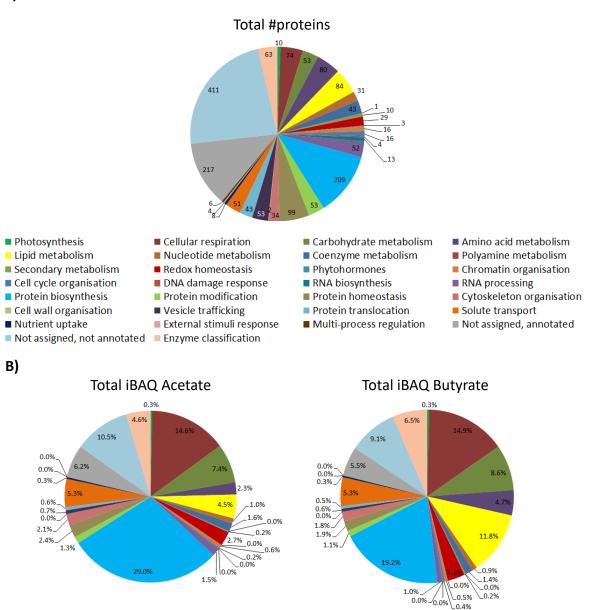

Figure 3. Overview of the *Polytomella* proteome revealed by the differential approach, represented per metabolic category as determined by Mercator. A) Total number of proteins identified in both acetate and butyrate-growing cells. B) Cumulative iBAQ values of total acetate and butyrate proteomes give an indication of the total protein abundance per category.

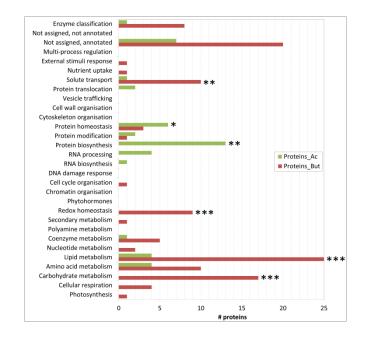

Figure 4. Focus on differentially expressed proteins, *i.e.* with a statistically significant difference in FC value. The number of proteins per category is given that are significantly more induced on either acetate or butyrate. Categories with a significant difference in FC proteins between either the acetate or the butyrate condition with respect to the background in the Fisher test are indicated with one asterisk (p-value<0.05), two asterisks (p<0.01) or three asterisks (p<0.001). Note that some categories do not contain any differentially expressed proteins, and the fact that some categories do not exhibit any FC proteins in either the acetate or butyrate condition does not mean there is no protein.

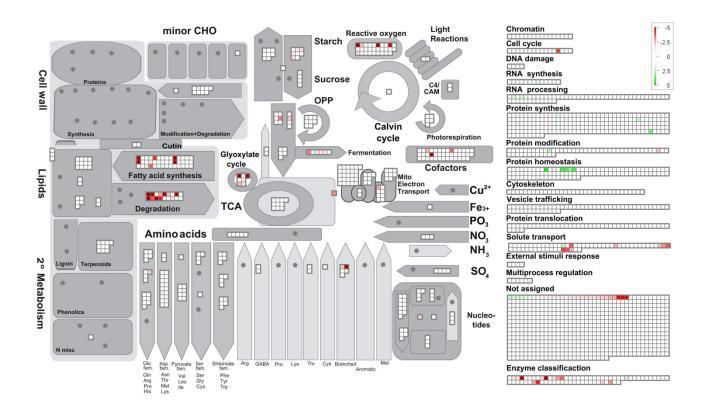

Figure 5. Schematic representation of cellular metabolism as a function of metabolic (sub)categories and log2 FoldChange values using the program MapMan. Metabolic categories were analyzed using the web program Mercator. For all entries with a FC score applies p-value <0.004. Note that for increased visibility of the lower range of the log2 FC scale was set from 5 to -5 whereas a few proteins on butyrate actually show higher FC values.

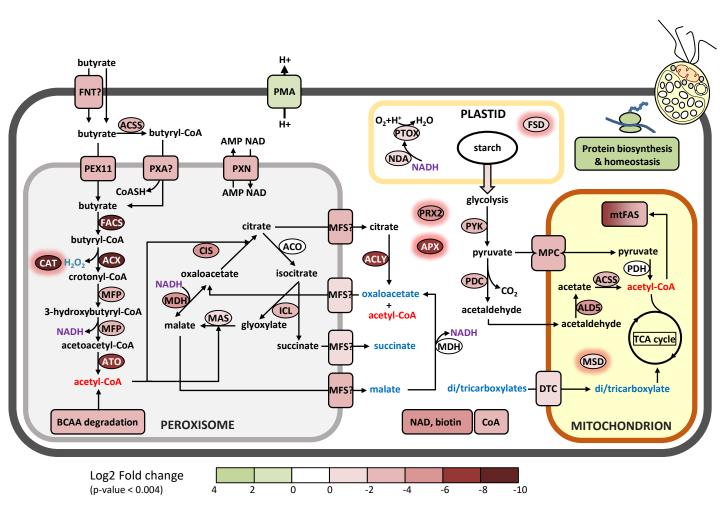

Figure 6. Proposed metabolic reconstruction of the assimilation pathway of butyrate in the peroxisome and interactions with other cell compartments. Taken into account are the FoldChange values and cellular localization based on software prediction (DeepLoc), manual verification of targeting signals and previous studies. The log2 FC acetate/butyrate value is indicated by the color codes. All di/tricarboxylic acids that may be imported into the mitochondria are indicated in blue. Enzymes with a red halo are involved in antioxidant defense. Enzymes codes and further information can be found in Table I and the Suppl. Table.

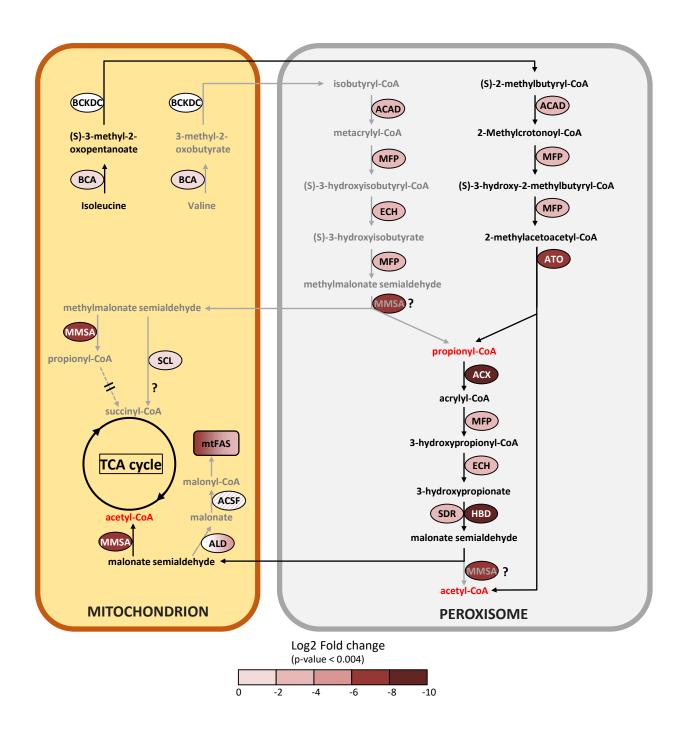

Figure 7. Metabolic reconstruction of the branched amino acid degradation pathway in the peroxisome and proposed interactions with the mitochondria. The log2 fold change But/Ac is indicated by the color codes. Further information can be found in Table I. Arrows in grey represent less likely or hypothetical pathways, proposed pathways use black arrows. ACSF exhibits an FC value with p>0.004. ALD color gradient indicates different isoforms with FC values between 0-6.
