Abstract   191 words

Group 1 innate lymphoid cells (G1-ILCs), including circulating natural killer (NK) cells and tissue-resident type 1 ILCs (ILC1s), are innate immune sentinels critical for responses against infection and cancer. In contrast to relatively uniform NK cells through the body, diverse ILC1 subsets have been characterized across and within tissues in mice, but their developmental and functional heterogeneity remain unsolved. Here, using multimodal *in vivo* approaches including fate-mapping and targeting of the interleukin 15 (IL-15)-producing microenvironment, we demonstrate that liver parenchymal niches support the development of a cytotoxic ILC1 subset lacking IL-7 receptor ($7R^-$ ILC1s). During ontogeny, fetal liver (FL) G1-ILCs arise perivascularly and then differentiate into $7R^-$ ILC1s within sinusoids. Hepatocyte-derived IL-15 supports parenchymal development of FL G1-ILCs to maintain adult pool of $7R^-$ ILC1s. IL-$7R^+$ ($7R^+$) ILC1s in the liver, candidate precursors for $7R^-$ ILC1s, are not essential for $7R^-$ ILC1 development in physiological conditions. Functionally, $7R^-$ ILC1s exhibit killing activity at steady state through granzyme B expression, which is underpinned by constitutive mTOR activity, unlike NK cells with exogenous stimulation-dependent cytotoxicity. Our study reveals the unique ontogeny and functions of liver-specific ILC1s, providing a detailed interpretation of ILC1 heterogeneity.

2

Introduction

Group 1 innate lymphoid cells (G1-ILCs) are innate immune cells contributing to surveillance of intracellular infections and tumors. G1-ILCs comprise two subtypes: natural killer (NK) cells and type 1 ILCs (ILC1s), that share fundamental features such as NK1.1$^+$NKp46$^+$ phenotype, expression of T-bet, and IFN-γ production (Jacquelot et al., 2022; Stokic-Trtica et al., 2020; Vivier et al., 2018). In contrast, mouse ILC1s can be distinguished from NK cells by their CD49a$^+$CD49b$^-$ phenotype, strict tissue-residency, and Eomes-independence (Daussy et al., 2014; Gasteiger et al., 2015; Peng et al., 2013; Sojka et al., 2014). In addition, developmental paths of ILC1s are basically distinct from NK cells, as confirmed by the identification of non-NK common ILC progenitors (ILCPs) expressing PLZF and/or PD-1 (Constantinides et al., 2015; Constantinides et al., 2014; Yu et al., 2016) and liver-resident Lin$^-$Sca-1$^+$Mac-1$^+$ (LSM) and Lin$^-$CD49a$^+$CD122$^+$ ILC1 precursors (Bai et al., 2021).

Functional differences between NK cells and ILC1s have also been recognized, though some confusion remains, particularly in cytotoxicity. In mice, NK cells are traditionally considered as more cytotoxic than ILC1s (Vivier et al., 2018), though this view has been questioned recently (Dadi et al., 2016; Kansler et al., 2022; Krabbendam et al., 2021; Nixon et al., 2022; Yomogida et al., 2021). Indeed, murine NK cells show low expression of cytotoxic molecules and only minimal cytotoxicity in their steady state (Fehniger et al., 2007). The cytotoxicity of NK cells requires the mTOR-dependent metabolic reprogramming mediated by cytokine signaling such as IL-15 or by NK receptor engagement (Marçais et al., 2014; Nandagopal et al., 2014), but whether such cytotoxic machinery also exists in ILC1s is unclear. By contrast, ILC1s can immediately respond and produce IFN-γ during liver injury (Nabekura et al., 2020) and virus infection (Weizman et al., 2017), highlighting the unique roles of ILC1s in the ignition of type 1 immunity in tissues. Thus, examining the development, function, and heterogeneity of ILC1s could lead to further understanding of local immune regulation and novel therapeutic strategies.

Recent high-resolution analysis has uncovered ILC1 heterogeneity and development. Liver ILC1s are separated into IL-7R-negative (7R$^-$) and -positive (7R$^+$) subsets (Friedrich et al., 2021; Sparano et al., 2022; Yomogida et al., 2021). G1-ILCs in the fetal liver (FL) are identified as precursors of ILC1s (Chen et al., 2022; Sparano et al., 2022), especially of Ly-49E$^+$ ILC1s that are included in 7R$^-$ ILC1s (Chen et al., 2022). In addition, 7R$^+$ ILC1s in the liver, salivary glands (SG), and small intestines can give rise to 7R$^-$ ILC1s in response to cytokines and inflammations (Friedrich et al., 2021), suggesting that 7R$^+$ ILC1s are also

3

84   potential precursors for 7R⁻ ILC1s. However, several reports have suggested different models.

85   In ILC1-related inflammation models reported so far, including contact hypersensitivity,

86   MCMV infection, and liver injury, ILC1s with high cytokine receptors (IL-7R, IL-18R,

87   and/or CD25) are induced and accumulate in the liver (Nabekura et al., 2020; Wang et al.,

88   2018; Weizman et al., 2019). Furthermore, an organ-wide single cell RNA sequencing

89   (scRNA-seq) analysis reveals that liver 7R⁻ ILC1s represent a unique population distinct from

90   SG and small intestines (McFarland et al., 2021), suggesting the absence of universal

91   differentiation programs of ILC1s conserved across tissues. Thus, concepts of ILC1

92   heterogeneity and development are still controversial.

93   Additionally, environmental factors regulating ILC1 development are poorly

94   understood. Accumulating evidence has shown that development and maintenance of ILCs are

95   strictly associated with their resident tissue microenvironment, called niche (Ikuta et al., 2021;

96   McFarland and Colonna, 2020; Murphy et al., 2022). G1-ILC homeostasis heavily depends on

97   interleukin 15 (IL-15), that is transpresented from hematopoietic and stromal cells as an IL-

98   15/IL-15Rα complex to locally promote the development, survival, and proliferation of

99   memory CD8 T cells, NKT cells, and G1-ILCs in various tissues (Ikuta et al., 2021; Klose et

100   al., 2014; Lodolce et al., 1998). However, how tissue environment regulates ILC1

101   homeostasis and whether specific niches control the formation of ILC1 heterogeneity are yet

102   to be characterized.

103   Based on fate-mapping, transfer studies, and targeting of the IL-15-producing

104   microenvironment, we have addressed the developmental processes of heterogenous ILC1

105   subsets. Adult liver (AL) 7R⁺ ILC1s are not converted to 7R⁻ ILC1s *in vivo* and RORα

106   deficiency results in selective reduction of 7R⁺ ILC1s, suggesting that 7R⁺ ILC1s are not

107   necessary for the development of 7R⁻ ILC1s. FL G1-ILCs originate from perivascular sites of

108   the liver and then infiltrate into sinusoids to give rise to AL 7R⁻ ILC1s. Hepatocyte-derived

109   IL-15 supports FL G1-ILCs development in parenchyma, thereby maintaining mature 7R⁻

110   ILC1s in sinusoids. Functionally, 7R⁻ ILC1s exert inflammation-independent cytotoxicity

111   through granzyme B expression, which is underpinned by their tonic mTOR activity. Our

112   findings reveal that 7R⁻ ILC1s represent an ILC subset with unique developmental processes

113   and unconventional native cytotoxicity distinct from NK cells and 7R⁺ ILC1s.

114

115 **Results**

116

117 **Fetal and adult liver contain *bona fide* ILC1s lacking IL-7R**

118 To characterize and make the relationships among fetal and adult G1-ILCs clear, we first

119 assessed their expression of NK- and ILC-signature molecules. FL G1-ILCs, adult tissue

120 ILC1s, and NK cells were identified as CD49a$^+$CD49b^{int}, CD49a$^+$CD49b^{lo}, and

121 CD49a$^-$CD49b$^+$ populations within G1-ILCs, respectively (Figure 1A). FL G1-ILCs highly

122 expressed CXCR6, TRAIL, and CD200R, resembling adult tissue ILC1s, though they

123 completely lacked IL-7R expression (Figure 1B and 1C). AL contains both IL-7R-negative

124 (7R$^-$) and -positive (7R$^+$) ILC1s (Figure 1C), as reported previously (Friedrich et al., 2021;

125 Sparano et al., 2022; Yomogida et al., 2021). In contrast, CD49a$^+$CD49b^{lo} ILC1s in bone

126 marrow (BM), corresponding to previously reported immature ILC1s (iILC1s) that have

127 ability to give rise to liver ILC1s (Klose et al., 2014), were mostly IL-7R$^+$, similar to other

128 tissues including the spleen, mesenteric lymph nodes, peritoneal cavity, and small intestines

129 (Figure 1C and 1D). Despite the differential IL-7R expression, the frequencies and numbers

130 of AL 7R$^-$ and 7R$^+$ ILC1s were not reduced in IL-7$^{-/-}$ mice (Figure 1–figure supplement 1A

131 and 1B), consistent with the basic property of G1-ILCs of being IL-7-independent (Klose et

132 al., 2014; Robinette et al., 2017).

133 We further assessed the relevance among G1-ILC subsets by bulk RNA sequencing

134 (RNA-seq). All analyzed G1-ILC populations expressed *Tbx21* (T-bet) but not *Rorc* (RORγt),

135 suggesting the lack of ILC3 contamination (Figure 1–figure supplement 1C). Consistent with

136 surface phenotype, FL G1-ILCs and AL 7R$^-$ ILC1s as well as BM iILC1s and AL 7R$^+$ ILC1s

137 shared high expression of ILC1 signature genes (*P2rx7*, *Zfp683*, and *Cd3g*) and low

138 expression of NK cell signature genes (*Sell*, *Klra4*, and *Klra8*) (Figure 1E). By contrast, 7R$^+$

139 ILC1s and BM iILC1s showed higher expression of genes related to cytokine responses (*Il7r*,

140 *Il2ra*, *Icos*, and *Kit*) compared to other G1-ILC subsets (Figure 1–figure supplement 1D).

141 Conversely, FL G1-ILCs and 7R$^-$ ILC1s poorly expressed cytokine receptor-related genes

142 (*Il7r*, *Il18r1*, and *Il18rap*) (Figure 1E) and exhibited less cytokine-responsive characters

143 (Figure 1–figure supplement 1E). Although FL G1-ILCs were unique in terms of their high

144 proliferative status (Figure 1–figure supplement 1F and 1G), principal component analysis

145 (PCA) revealed that the overall transcriptional state of FL G1-ILCs was close to 7R$^-$ ILC1s

146 (Figure 1F). 7R$^+$ ILC1s located rather close to BM iILC1s in PCA, suggesting their cross-

147 tissue similarity. These results show the transcriptional resemblance between FL G1-ILCs and

148 AL 7R$^-$ ILC1s or between BM iILC1s and AL 7R$^+$ ILC1s.

149   Given the ILC1-like transcriptional programs and T-bet$^+$Eomes$^-$ phenotype of FL

150   G1-ILCs and AL 7R$^-$ ILC1s (Figure 1G), they were considered as ILC1s but not NK cells. To

151   precisely verify their lineage, we performed fate-mapping of ILCPs by using PLZF-GFP-Cre

152   Rosa26-YFP reporter (PLZF-fm) mice (Constantinides et al., 2014). In these mice, ILCP

153   progenies including ILC1s, ILC2s, and ILC3s but not LTi or NK cells are preferentially

154   labelled by YFP, though a certain ratio of blood cells expresses YFP due to the pre-

155   hematopoietic PLZF expression (Constantinides et al., 2014). To remove this background YFP

156   labelling, we used chimeric mice reconstituted with YFP$^-$Lin$^-$Sca1$^+$c-Kit$^+$ (LSK) cells sorted

157   from BM of PLZF-fm mice. In the chimeric mice, AL 7R$^-$ and 7R$^+$ ILC1s as well as other

158   adult tissue ILC1s prominently expressed YFP (Figure 1H and 1I). A similar trend was

159   observed when using straight PLZF-fm mice or chimeric mice reconstituted with FL LSK

160   cells from PLZF-fm mice (Figure 1–figure supplement 1H and 1I). Furthermore, FL G1-ILCs

161   mostly expressed YFP in straight PLZF-fm mice (Figure 1J), in line with a previous fate-

162   mapping study of neonatal liver G1-ILCs (Constantinides et al., 2015). Thus, these results

163   indicate that *bona fide* ILC1s lacking IL-7R are enriched in FL and AL.

164

7R$^+$ ILC1s minimally contribute to the development of 7R$^-$ ILC1s

166   A previous study reported that 7R$^+$ ILC1s behaved as the precursors of 7R$^-$ ILC1s when

167   cultured *in vitro* or transferred into lymphopenic mice (Friedrich et al., 2021). However, in the

168   liver, while 7R$^+$ ILC1s were nearly absent in infants and accumulated with age, 7R$^-$ ILC1s

169   were predominant in young mice, decreased with age, and eventually depleted (Figure 2A–

170   2C). These observations suggest that the development and maintenance of 7R$^-$ ILC1s are

171   independent from 7R$^+$ ILC1s in physiological conditions.

172   To test this hypothesis, we first explored whether there were molecular pathways

173   controlling the development of each ILC1 population individually. RNA-seq revealed that

174   7R$^+$ ILC1s highly expressed RORα and were positively enriched with gene sets "RORA

175   activates gene expression" relative to 7R$^-$ ILC1s, based on gene set enrichment analysis

176   (GSEA) (Figure 2D). We therefore generated ROR$\alpha^{-/-}$ mice to test the effect of RORα for

177   7R$^+$ ILC1s. As ROR$\alpha^{-/-}$ mice tend to die within four weeks after birth, we analyzed adult

178   ROR$\alpha^{+/-}$ mice or two weeks old ROR$\alpha^{-/-}$ mice. 7R$^+$ ILC1s were significantly reduced in

179   ROR$\alpha^{+/-}$ mice, while NK cells and 7R$^-$ ILC1s were unchanged (Figure 2E). In ROR$\alpha^{-/-}$ mice,

180   though whole ILC1s were significantly reduced as reported recently (Song et al., 2021), 7R$^+$

181   ILC1s were the subset most apparently affected (Figure 2F). These data suggest that the

6

182   development of 7R$^-$ ILC1s do not significantly depend on the presence of 7R$^+$ ILC1s.

183   To make the developmental relationships between 7R$^-$ and 7R$^+$ ILC1s clearer, we

184   conducted adoptive transfer experiments under physiological conditions by using unirradiated

185   CD45.1 WT host mice. 7R$^-$ and 7R$^+$ ILC1s were isolated from AL, transferred, and the host

186   liver were analyzed. For at least 2 months, little conversion was observed between 7R$^-$ and

187   7R$^+$ ILC1s (Figure 2G–I). In addition, transferred BM iILC1s gave rise to AL 7R$^+$ ILC1s but

188   not to 7R$^-$ ILC1s (Figure 2–figure supplement 1A and 1B), consistent with their

189   transcriptional resemblance. However, parabiosis experiments showed that the replacement

190   rate of AL 7R$^+$ ILC1s were low (<5%), though significantly higher than that of 7R$^-$ ILC1s

191   (Figure 2–figure supplement 1C), suggesting that both ILC1 subsets are tissue-resident. Thus,

192   whether BM iILC1s actually contribute to AL 7R$^+$ ILC1 pool is still unclear. To test the

193   phenotypical stability of ILC1s in inflammatory states, we injected IL-15/IL-15Rα complex

194   repeatedly into host mice that had received CPD-labeled 7R$^-$ and 7R$^+$ ILC1s. NK cells and

195   7R$^+$ ILC1s proliferated more than 7R$^-$ ILC1s after the stimulation (Figure 2J), consistent with

196   their basal Ki-67 expression levels (Figure 1–figure supplement 1G) and properties of

197   cytokine responsiveness (Figure 1–figure supplement 1E). 7R$^-$ and 7R$^+$ ILC1s were stable

198   even after the IL-15/IL-15Rα stimulation (Figure 2K), confirming their stability in activated

199   states. These results show that 7R$^+$ ILC1s were rarely converted to 7R$^-$ ILC1s and not

200   essential for the development of 7R$^-$ ILC1s under physiological conditions.

201

202   **FL G1-ILCs arise at hepatic parenchyma and give rise to 7R$^-$ ILC1s in sinusoids**

203   We next address the contribution of FL G1-ILCs to the development of AL 7R$^-$ ILC1s.

204   Adoptively transferred FL G1-ILCs differentiated into CD49a$^+$CD49b^{lo} mature ILC1s in AL

205   (Figure 3A) and they completely lacked IL-7R (Figure 3B). To confirm the direct contribution

206   of FL G1-ILCs to the adult pool of 7R$^-$ ILC1s, we performed fate-mapping experiments using

207   NKp46-CreERT2 mice (Nabekura and Lanier, 2016) crossed with Rosa26-tdTomato mice.

208   After tamoxifen injection into pregnant mice at E17.5, liver of neonatal and 4 weeks old pups

209   were analyzed. TdTomato expression was clearly restricted to IL-7R$^-$ fractions within

210   neonatal G1-ILCs and AL ILC1s (Figure 3C–3E, Figure 3–figure supplement 1A), consistent

211   with previous studies (Chen et al., 2022; Sparano et al., 2022). As shown in these studies,

212   fate-mapped 7R$^-$ ILC1s showed a skewed expression of Ly49E/F, though they also contained

213   Ly49E/F$^-$ population (20–25%) (Figure 3–figure supplement 1B–1D). Labeling efficiency

214   was 40% in neonatal IL-7R$^-$ G1-ILCs and 20% in 7R$^-$ ILC1s in 4 weeks old mice (Figure 3F

215   and 3G). These results confirm a direct, albeit partial, contribution of FL G1-ILCs to the adult

7

216   pool of 7R$^-$ ILC1s.

217   To investigate the detailed developmental process of FL G1-ILCs and AL ILC1s *in*

218   *vivo*, we examined their spatiotemporal distributions. In immunostaining analysis, FL G1-

219   ILCs were identified as NKp46$^+$ cells in WT mice (Figure 4A). AL NK cells and ILC1s were

220   identified as NKp46$^+$GFP$^-$ and NKp46$^+$GFP$^+$ cells in CXCR6$^{GFP/+}$ mice, respectively (Figure

221   4B and Figure 5–figure supplement 1A). In E18.5 liver, FL G1-ILCs mostly distributed at

222   perivascular sites, outside of the sinusoidal lumen (here termed parenchyma) (Figure 4A). In

223   contrast, over 85% of whole ILC1s and NK cells were within sinusoids in AL (Figure 4B and

224   4C). Although we could not detect IL-7R expression on ILC1s by immunofluorescence, flow

225   cytometry (FCM)-based analysis of intravenous (i.v.) CD45.2 staining confirmed similar

226   intravascular locations of 7R$^-$ and 7R$^+$ ILC1s as well as NK cells, T cells, and NKT cells in

227   AL (Figure 4D and 4E). In contrast, ILC2s were not efficiently labeled by i.v. staining,

228   consistent with perivascular localization of liver ILC2s observed so far (Dahlgren et al., 2019).

229   Interestingly, a population of AL Lin$^-$Sca-1$^+$Mac-1$^+$ (LSM) cells, local precursors for ILC1s

230   (Bai et al., 2021), were also not well labeled by i.v. staining. Thus, there are localization shifts

231   between ILC1 precursors and mature ILC1s in the liver: FL G1-ILCs and some LSM cells

232   distribute to parenchyma, whereas AL G1-ILCs including 7R$^-$ ILC1s reside within sinusoids.

233   These observations suggest that FL G1-ILCs arise at parenchyma and then infiltrate into

234   sinusoids during maturation toward 7R$^-$ ILC1s.

235

236   **Hepatocyte-derived IL-15 supports the parenchymal development of 7R$^-$ ILC1s**

237   Given that the possible origins of FL G1-ILCs and 7R$^-$ ILC1s are liver parenchyma, we asked

238   the role of parenchymal microenvironments for ILC1 development. Since IL-15,

239   transpresented as an IL-15/IL-15Rα complex, is a local determinant of G1-ILC homeostasis

240   (Ikuta et al., 2021), we generated IL-15-floxed mice and crossed them with several Cre-driver

241   lines. Reanalysis of single nuclei RNA-seq (snRNA-seq) data of whole liver cells from Liver

242   Cell Atlas (www.livercellatlas.org) revealed that *Il15* gene was highly expressed by

243   macrophages and endothelial cells and, to a lesser extent, by hepatocytes, while *Il15ra*

244   expression was prominent in hepatocytes (Figure 5A, 5B, and Figure 5–figure supplement

245   1B). We therefore focused on IL-15 produced by hepatocytes, macrophages, and endothelial

246   cells. To target parenchymal IL-15, we generated Alb-Cre IL-15-flox/flox (f/f) mice (IL-15^{Alb-}

247   ^{Cre} mice), which lacked IL-15 in hepatocytes. In IL-15$^{Alb-Cre}$ mice, FL G1-ILCs were

248   significantly reduced (Figure 5C). Notably, IL-15$^{Alb-Cre}$ mice also showed reduction of AL

8

249   7R$^-$ ILC1s in contrast to unchanged NK cells, 7R$^+$ ILC1s, and NKT cells (Figure 5D, 5E, and

250   Figure 5–figure supplement 1C), despite their similar intravascular localizations. These data

251   corroborate the precursor-progeny relationship of FL G1-ILCs and AL 7R$^-$ ILC1s and also

252   the parenchymal origin of 7R$^-$ ILC1s. To further define the IL-15 niches for G1-ILCs, we

253   generated IL-15$^{\text{Lyve1-Cre}}$ mice, which target vascular IL-15 sources including sinusoidal

254   endothelial cells and a fraction of hematopoietic cells (Lim et al., 2018; Pham et al., 2010). In

255   IL-15$^{\text{Lyve1-Cre}}$ mice, all AL G1-ILC subsets were significantly reduced (Figure 5F). We

256   analyzed another mouse line targeting intravascular IL-15 sources, IL-15$^{\text{LysM-Cre}}$ mice, which

257   lack IL-15 in myeloid cells. IL-15$^{\text{LysM-Cre}}$ mice showed similar two-fold reductions of AL NK

258   cells, 7R$^-$ ILC1s, and 7R$^+$ ILC1s (Figure 5G), confirming the similar IL-15 requirements

259   among all G1-ILC subsets. Notably, expression of Bcl-2, a survival factor downstream of IL-

260   15, was downregulated in all G1-ILCs of IL-15$^{\text{Lyve1-Cre}}$ mice (Figure 5H and 5I), whereas Bcl-

261   2 and Ki-67 levels were unchanged in IL-15$^{\text{Alb-Cre}}$ mice (Figure 5J and 5K). These results

262   indicate that parenchymal IL-15 has no direct impact on mature 7R$^-$ ILC1s in sinusoids

263   whereas intravascular IL-15 directly supports the survival of all AL G1-ILCs. IL-15$^{\text{Alb-Cre}}$

264   mice had reduced Lin$^-$CD122$^+$CD49a$^+$ ILC1 precursors in AL (Figure 5–figure supplement

265   1D), suggesting an impaired development of 7R$^-$ ILC1s. Thus, these data demonstrate that

266   hepatocyte-derived IL-15 supports the development of 7R$^-$ ILC1s at parenchyma, thereby

267   maintaining AL 7R$^-$ ILC1s infiltrated in sinusoids.

268

269   **Steady-state mTOR activity confers granzyme B-mediated cytotoxicity in 7R$^-$ ILC1s**

270   Cytotoxicity is one of the most pivotal functions of G1-ILCs, though the contribution of

271   ILC1s remains controversial. By focusing on the ILC1 heterogeneity, we attempted to

272   describe the G1-ILC effector function in detail. In steady state, minimal levels of granzyme B

273   and death ligands were found on NK cells, while 7R$^-$ ILC1s expressed both granzyme B and

274   TRAIL, the latter of which was also expressed on 7R$^+$ ILC1s (Figure 6A, Figure 6–figure

275   supplement 1A, and 1B) (Friedrich et al., 2021). In line with this, freshly isolated 7R$^-$ ILC1s

276   remarkably lysed multiple tumor cells including YAC-1 (Figure 6B), Hepa1-6 (Figure 6C),

277   and B16F10 cells (Figure 6D). By contrast, NK cells and 7R$^+$ ILC1s showed only slight or no

278   cytotoxicity against these tumor cells, consistent with a previous study showing minimal

279   cytotoxicity of unstimulated NK cells (Fehniger et al., 2007). To determine the effector

280   pathways 7R$^-$ ILC1s rely on, we added concanamycin A (CMA), an inhibitor for

281   perforin/granzyme pathways (Kataoka et al., 1994), and neutralizing antibodies for TRAIL

282   and FasL to the coculture systems. Killing of Hepa1-6 cells by 7R$^-$ ILC1s was markedly

9

283   inhibited by CMA, and to a lesser extent by anti-TRAIL antibody (Figure 6E). Despite the

284   expression of granzyme A in NK cells and granzyme C in 7R$^+$ ILC1s (Nixon et al., 2022)

285   (Figure 6–figure supplement 1C and 1D), CMA had no effect to their cytotoxicity. Other

286   granzyme genes (*Gzmf*, *k*, *n*, and *m*) were undetectable in ILC1s (data not shown). These

287   results suggest that granzyme B plays a major role in the cytotoxicity of 7R$^-$ ILC1s.

288   Cellular amount of granzyme B is well correlated to and primarily responsible for the

289   NK cell cytotoxicity (Bhat and Watzl, 2007; Gwalani and Orange, 2018; Prager et al., 2019).

290   Although granzyme B expression and killing capacity of NK cells are weak at steady state,

291   stimulation by cytokines, especially by IL-15, enable to induce both of them (Fehniger et al.,

292   2007; Marçais et al., 2014; Prager et al., 2019). To test whether 7R$^-$ ILC1s share such an

293   activation machinery, we analyzed their granzyme B expression after the stimulation. We

294   found that IL-15/IL-15Rα injection more efficiently enhanced granzyme B on NK cells and

295   7R$^+$ ILC1s than 7R$^-$ ILC1s, and thereby the granzyme B level on NK cells got comparable to

296   7R$^-$ ILC1s (Figure 6A). IL-15/IL-15Rα also triggered the phosphorylation of STAT5, Akt,

297   and ribosomal protein S6 (a target of mTOR), which are critical for the IL-15-induced effector

298   function (Ali et al., 2015), in NK cells and 7R$^+$ ILC1s but to a lesser degree in 7R$^-$ ILC1s

299   (Figure 6F, 6G, Figure 6–figure supplement 1E, and 1F). These data suggest that the cytotoxic

300   capacity of 7R$^-$ ILC1s are different from that of NK cells in terms of responsiveness and

301   requirement for the cytokine stimulation. Interestingly, the phosphorylation level of S6 was

302   rather higher in ILC1s than NK cells in unstimulated mice (Figure 6F and 6G). Notably,

303   injection of rapamycin, an mTOR complex inhibitor, downregulated granzyme B expression

304   in 7R$^-$ ILC1s to a level comparable to that in NK cells (Figure 6H and 6I). By contrast,

305   granzyme B levels in NK cells and 7R$^+$ ILC1s were unaffected. Collectively, these results

306   show that 7R$^-$ ILC1s exhibit cytotoxicity in their steady state through granzyme B expression,

307   which is supported by their constitutive mTOR activation.

308

Discussion

In this study, we have characterized the developmental process and functional heterogeneity of liver G1-ILCs. Hepatocytes shape IL-15 niches supporting parenchymal development of FL G1-ILCs, that differentiate into 7R⁻ ILC1s in sinusoids. Functionally, 7R⁻ ILC1s exhibit granzyme B-mediated cytotoxicity in steady state, in sharp contrast to less cytotoxic resting NK cells.

ILC1 heterogeneity has been extensively addressed recently. In the liver, ILC1s are separated into IL-7R⁻ and IL-7R⁺ populations (Friedrich et al., 2021; Sparano et al., 2022; Yomogida et al., 2021), the latter of which can differentiate into the former when cultured *in vitro* or transferred into lymphopenic mice (Friedrich et al., 2021). However, we show that 7R⁻ and 7R⁺ ILC1s behave like independent subsets under physiological conditions: decline of 7R⁻ ILC1s and accumulation of 7R⁺ ILC1s with age, requirements for RORα specifically in 7R⁺ ILC1s, and phenotypical stability between 7R⁻ and 7R⁺ ILC1s when transferred into WT host mice. Such a contradiction might be due to the highly nutrient- and cytokine-accessible environments in the culture systems and lymphopenic hosts that might trigger non-physiological activation and phenotypic shift of 7R⁺ ILC1s. Indeed, our model rather gives an explanation for the ILC1 heterogeneity in inflammatory disease models using healthy mice observed so far. In mouse models of contact hypersensitivity, MCMV infection, and liver injury, ILC1s with high expression of cytokine receptors (IL-7R, CD25, and/or IL-18R) highly proliferate and accumulate in AL, thereby forming the memory and protecting liver from infection and injury (Nabekura et al., 2020; Wang et al., 2018; Weizman et al., 2019). AL 7R⁺ ILC1s resemble such "memory-like" or "activated" ILC1s in terms of the surface phenotype and high proliferation potentials. These observations suggest a hypothesis that a preferential proliferation of pre-existing stable 7R⁺ ILC1s, rather than inflammation-specific ILC1s induced from naïve ILC1s, may contribute to liver immunity and homeostasis.

Several previous studies have pointed out the precursors for ILC1s: BM iILC1s (Klose et al., 2014), FL G1-ILCs (Constantinides et al., 2015; Daussy et al., 2014), and local precursors in the liver such as LSM cells and Lin⁻CD122⁺CD49a⁺ cells (Bai et al., 2021). In particular, FL G1-ILCs are precursors for AL Ly-49E⁺ ILC1s (Chen et al., 2022; Sparano et al., 2022). Although AL Ly-49E⁺ ILC1s are included in and account for 30–40% of AL 7R⁻ ILC1s, fate-mapping reveals that FL-derived 7R⁻ ILC1s contain also an Ly49E/F⁻ population (20–25%), suggesting further heterogeneity in FL-derived ILC1s. Considering the partial contribution (about 50%) of FL G1-ILCs to AL 7R⁻ ILC1 pool estimated by fate-mapping,

11

343   local ILC1 precursors such as LSM cells and $Lin^-CD122^+CD49a^+$ cells might be the other

344   sources for $7R^-$ ILC1s. By contrast, the origin of AL $7R^+$ ILC1s remains to be solved. We

345   show that BM iILC1s have a potential to differentiate into AL $7R^+$ ILC1s, but the actual

346   contribution is unclear. As both AL $7R^-$ and $7R^+$ ILC1s were rarely replaced during

347   parabiosis experiments using adult mice, it is possible that a transiently migrated population

348   derived from BM settle and give rise to $7R^+$ ILC1s in the liver during neonatal period, as

349   discussed previously (Sparano et al., 2022). Further investigations using a specific tracing

350   approach such as fate-mapping of BM iILC1s are required to determine their precise

351   developmental potency.

352   Development and maintenance of ILCs strictly depend on their resident tissue

353   microenvironments, called niche (Ikuta et al., 2021; Kotas and Locksley, 2018; McFarland

354   and Colonna, 2020; Murphy et al., 2022). IL-15 is a cytokine crucial for G1-ILC homeostasis.

355   IL-15-producing cells shape the niches for G1-ILCs within various tissues via the IL-15/IL-

356   15Rα transpresentation (Cepero-Donates et al., 2016; Cui et al., 2014; Liou et al., 2014;

357   Mortier et al., 2009), yet IL-15 niches specific for ILC1s remained unclear. Using a

358   combination of imaging and cell-specific IL-15 knockout approaches, we unveil the

359   parenchymal origins of $7R^-$ ILC1s as well as FL G1-ILCs and identify hepatocytes as an IL-

360   15-producing niche supporting $7R^-$ ILC1 development. Parenchymal distribution of FL G1-

361   ILCs, reminiscent of FL hematopoietic stem cells (HSCs) (Khan et al., 2016; Lewis et al.,

362   2021), might be partly due to the immaturity of hepatic vasculature in that period. Since FL

363   G1-ILCs and FL HSCs are also similar in that they eventually infiltrate into blood vessels

364   (Lewis et al., 2021), it would be of interest to address the mechanism underlying their

365   neonatal dynamics. In addition, it is still unclear why hepatocyte-derived IL-15 has such a

366   local effect despite many fenestrae and the lack of a basement membrane on liver sinusoids.

367   One possible explanation is that the transpresentation of IL-15/IL-15Rα by hepatocytes may

368   require direct contact to target cells, as dendritic cells do (Mortier et al., 2008). Given that

369   hepatocytes prominently express *Il15ra* gene and its deletion results in the reduction of whole

370   IL-15-dependent lymphocytes in the liver (Cepero-Donates et al., 2016), it is also possible

371   that hepatocytes may produce IL-15Rα as a soluble form, that binds to other cell-derived IL-

372   15 to exert non-local effects.

373   Traditionally, ILC1s are regarded as less cytotoxic than NK cells in mice, whereas

374   recent studies have challenged this theory (Dadi et al., 2016; Di Censo et al., 2021; Kansler et

375   al., 2022; Nixon et al., 2022; Yomogida et al., 2021). Our study provides two possible

12

376   explanations for this discrepancy. First, the age of mice selected for analysis influence the

377   composition and overall cytotoxicity of ILC1s. We and others (Chen et al., 2022; Friedrich et

378   al., 2021; Nixon et al., 2022) showed that ILC1s were heterogenous in their cytotoxicity. Due

379   to the age-dependent reduction of highly cytotoxic $7R^-$ ILC1s, the overall cytotoxicity of

380   ILC1s in the liver should decline with age. Second, the effector program of $7R^-$ ILC1s differ

381   from NK cells in its nature, especially in terms of cytokine responsiveness. Freshly isolated

382   NK cells exhibit low expression of cytotoxic molecules and only minimal cytotoxicity

383   (Fehniger et al., 2007), while stimulation by IL-15 confers granzyme B expression and

384   cytotoxicity on NK cells via mTOR-dependent metabolic reprogramming (Marçais et al.,

385   2014; Nandagopal et al., 2014). Conversely, we show that $7R^-$ ILC1s exhibit prominent

386   granzyme B-mediated cytotoxicity via mTOR activity at steady state, though they are less

387   responsive to cytokines than NK cells and $7R^+$ ILC1s. These findings suggest that $7R^-$ ILC1s

388   are "ready-to-kill" sentinels that contribute to the tonic immune surveillance, which is

389   followed later by the response of activated and proliferated NK cells and $7R^+$ ILC1s.

390   Taken together, our study provides insight into the complex ILC1 ontogeny by

391   revealing relationships among heterogenous ILC1 subsets, their developmental dynamics, and

392   niche dependence. Our findings highlight the intrinsic cytotoxic programs of $7R^-$ ILC1s

393   unlike NK cells, proposing them as critical steady-state sentinels against infection prevention

394   and tumor surveillance and bringing the possibility of local therapeutic targeting of ILC1

395   function.

396

Materials and Methods

Mice

C57BL/6J mice were purchased from Japan SLC (Hamamatsu, Japan). IL-7$^{-/-}$ mice were obtained by IL-7-flox mice developed in our laboratory (Liang et al., 2012) with Cre-mediated germ-line deletion. PLZF-IRES-EGFP-Cre (Constantinides et al., 2014) mice were provided by Dr. M. Miyazaki at Kyoto University and crossed with Rosa26-YFP mice (Srinivas et al., 2001). RORα knockout (ROR$\alpha^{-/-}$) mice were generated by CRISPR/Cas9 gene editing in our laboratory and will be reported in detail elsewhere. CXCR6-GFP KI (CXCR6$^{GFP/+}$) mice were provided by Dr. H. Ohno. IL-15-flox mice were generated in our laboratory (Cui et al., under review) and bred with Alb-Cre mice (Postic et al., 1999) and Lyve1-Cre mice (Pham et al., 2010), which were kindly supplied by Dr. Mark A. Magnuson at Vanderbilt University and by Dr. Jason Cyster at University of California San Francisco, respectively. NKp46-CreERT2 Tg mice (Nabekura and Lanier, 2016) were provided by Dr. T. Nabekura and Dr. Lewis L. Lanier and crossed with Rosa26-tdTomato (Madisen et al., 2010) mice. For fetal experiments, the noon when the vaginal plug was detected was considered as embryonic day (E) 0.5. All mice were maintained under specific pathogen-free conditions in the Experimental Research Center for Infectious Diseases at the Institute for Life and Medical Sciences, Kyoto University. All procedures were carried out under sevoflurane or isoflurane anesthesia to minimize animal suffering. All mouse protocols were approved by the Animal Experimentation Committee of the Institute for Life and Medical Sciences, Kyoto University.

Cell preparation and isolation

To protect ILC1s from NAD$^+$-induced cell death (NICD) (Stark et al., 2018), mice were intravenously (i.v.) injected with 40 μg ARTC2.2 blocking nanobody (BioLegend, San Diego, CA, USA) 30 min before sacrificing the mice in several experiments. Fetal liver, adult liver, spleen, peripheral (axillary, brachial, and inguinal) lymph nodes, and mesenteric lymph nodes were dissociated mechanically and passed through 70-μm cell strainers (Greiner Bio-One, Milan, Italy). Adult liver leukocytes were then separated by centrifugation through 40% Percoll. Peritoneal cavity was washed by 5 mL of PBS and the wash fluid was extracted using a syringe and a 21 G needle (Terumo Corporation, Tokyo, Japan). BM cells were obtained by flushing out the marrow fraction of femurs and tibias. To collect salivary gland cells, submandibular and sublingual glands were minced with scissors and incubated at 37°C for 1

14

430   hour in RPMI 1640 medium containing 10% fetal bovine serum, 1 mg/mL collagenase D, and

431   50 μg/mL DNase I (Sigma-Aldrich, St. Luis, MO, USA). The cell suspension was filtered

432   through a 70-μm cell strainer and purified using 40% Percoll. For the isolation of intestinal

433   lamina propria lymphocytes, small intestines were flushed out and Peyer's patches were

434   excised. The intestines were opened longitudinally, cut into 1-cm pieces, and incubated at

435   37°C for 30 min in PBS with 5 mM EDTA to remove epithelial cells. The incubated pieces

436   were then minced and digested by RPMI 1640 medium containing 10% fetal bovine serum,

437   1.25 mg/mL collagenase D, and 50 μg/mL DNase I. The tissue suspension was passed through

438   a 70-μm cell strainer and lymphocytes were purified by 40% Percoll.

439

440   **Flow cytometry and cell sorting**

441   Following fluorescent dye- or biotin-conjugated antibodies (BioLegend, San Diego, CA,

442   USA; Thermo Fisher Scientific, Waltham, MA, USA; BD Bioscience, San Jose, CA, USA;

443   TONBO Biosciences, San Diego, CA, USA) were used: CD3ε (145-2C11), NK1.1 (PK136),

444   NKp46 (29A1.4), CD49a (HMα1), CD49b (DX5), IL-7Rα (A7R34), CXCR6 (SA051D1),

445   TRAIL (N2B2), CD69 (H1.2F3), CD200R (OX-110), CXCR3 (CXCR3-173), CD25 (PC61),

446   Thy-1.2 (30-H12), KLRG1 (2F1/KLRG1), CD11b (M1/70), CD62L (MEL-14), Eomes

447   (Dan11mag), T-bet (4B10), CD45.1 (A20), CD45.2 (104), CD45 (30-F11), Ki-67 (SolA15),

448   Bcl-2 (BCL/10C4), CD31 (MEC13.3), LYVE-1 (LVY7), CD122 (TM-β1), Ter119 (Ter119),

449   F4/80 (BM8), Gr-1 (RB6-8C5), CD19 (6D5), B220 (RA3-6B2), TCRβ (H57−597), FcεRI

450   (MAR-1), PD-1 (29F.1A12), α4β7 (DATK32), Sca-1 (E13-161.7), c-Kit (2B8), Flt3 (A2F10),

451   granzyme B (NGZB), granzyme C (SFC1D8), FasL (MFL3), Ly49E/F (CM4), p-S6

452   (D57.2.2E), p-STAT5 (47), and p-Akt (S473) (M89-61). Biotinylated monoclonal antibodies

453   were detected with APC- or Brilliant Violet 421-conjugated streptavidin (Thermo Fisher

454   Scientific). For intracellular staining of Eomes, T-bet, Bcl-2, Ki-67, and granzymes, cells were

455   stained for surface antigens, fixed, permeabilized, and stained using Foxp3 Staining Buffer

456   Set or IC Fixation Buffer (Thermo Fisher Scientific). For intracellular staining of p-S6, p-

457   STAT5, and p-Akt (S473), cells were stained for surface antigens, fixed, permeabilized, and

458   stained using BD Phosflow Buffer (BD Biosciences). Flow cytometry and cell sorting were

459   performed on BD FACSVerse or BD LSRFortessa X-20 flow cytometers (BD Biosciences)

460   and BD FACS Aria II or Aria III cell sorters (BD Biosciences), respectively. Data were

461   analyzed on FlowJo software (FlowJo, Ashland, OR, USA). Debris and dead cells were

462   excluded from analysis by forward and side scatter and propidium iodide (PI) gating. In

15

463 figures, values in quadrants, gated areas, and interval gates indicate percentages in each
464 population.

465

466 **Fate-mapping experiment**

467 Fate-mapping of ILCPs in BM or FL were performed as described previously (Constantinides
468 et al., 2014). In brief, 1×10^4 YFP$^-$Lin$^-$Sca1$^+$c-Kit$^+$ (LSK) cells isolated from BM or FL of
469 PLZF-GFP-Cre Rosa26-YFP mice were injected i.v. into lethally (9 Gy) irradiated CD45.1
470 WT mice to remove the random YFP labelling occurred prior to the hematopoiesis. The
471 recipient mice were analyzed 5 weeks after the transplantation. Straight PLZF-GFP-Cre
472 Rosa26-YFP mice were also analyzed to confirm the results. For fate-mapping of FL G1-ILCs
473 in NKp46-CreERT2 Rosa26-tdTomato mice, 4 mg tamoxifen (Sigma-Aldrich) was
474 intraperitoneally injected into pregnant mothers at E17.5. Neonatal (postnatal day 0–4) and 4
475 weeks old pups were analyzed.

476

477 **RNA sequencing (RNA-seq) and data analysis**

478 For bulk RNA-seq, freshly sorted G1-ILC populations (1×10^3 cells) were lysed with Buffer
479 RLT (Qiagen, Hilden, Germany) and purified with RNAClean XP (Beckman Coulter, Brea,
480 CA, USA). Double strand cDNA was synthesized, and sequencing libraries were constructed
481 using SMART-seq HT Plus kit (Takara Bio, Otsu, Japan). Sequencing was performed with
482 150 bp paired-end reads on the Illumina HiSeq X sequencer (Illumina, San Diego, CA, USA).
483 fastp (Chen et al., 2018) was used to assess sequencing quality and to exclude low-quality
484 reads and adaptor contaminations. Reads were mapped on the mouse reference genome
485 (mm10) using HiSat2. The read counts were determined at the gene level with featureCounts.
486 Normalization of gene expression levels and differential gene expression analysis were
487 performed using DESeq2. Genes were considered as differentially expressed genes (DEG)
488 when they had an adjusted p (p_{adj}) value < 0.05 and fold changes > 1.0. Metascape (Zhou et
489 al., 2019) and gene set enrichment analysis (GSEA, Broad Institute) was used for enrichment
490 analysis. For reanalysis of single nuclei RNA-seq (snRNA-seq) data of whole liver cells in
491 mice (Liver Cell Atlas; www.livercellatlas.org), normalization, scaling, and UMAP
492 clustering using first 5 dimensions in principal component analysis (PCA) of scaled count
493 matrix were performed on R package Seurat 4.0.2.

494

495 ***In vivo* treatment**

16

496 For *in vivo* stimulation of G1-ILCs, mice were administrated intraperitoneally (i.p.) with 2 μg

497 IL-15/IL-15Rα complex (the RLI form as in Mortier et al., 2006, provided by Dr. J. M.

498 Dijkstra) once a day. After 18 hours, liver cells were isolated and analyzed by flow cytometry

499 to detect cytotoxic molecule expression. For rapamycin treatment, 30 μg rapamycin in 100 μL

500 corn oil was injected i.p. into mice 18 hours before the analysis.

501

Intrasplenic injection

503 A small incision was made on the left flank of anesthetized mice and the lower pole of the

504 spleen was gently exposed. Cell suspension (50 μL) was slowly injected into the spleen by a

505 0.3 mL insulin syringe with a 29 G needle (BD Biosciences). Cotton wool was applied to the

506 spleen for several minutes after the injection to stop bleeding.

507

Adoptive transfer experiments

509 NK cells, 7R$^-$ ILC1s, 7R$^+$ ILC1s, and BM iILC1s (2×10^4–5×10^4 cells) and FL G1-ILCs (1

510 $\times 10^5$ cells) were sorted from adult and E18.5 CD45. 1 WT mice, respectively. Each G1-ILC

511 population was adoptively transferred into CD45.2 WT mice by intrasplenic injection. At the

512 indicated time points, cells were isolated from the liver of recipient mice and analyzed by

513 flow cytometry. To assess the stability and the proliferation capacity of 7R$^-$ ILC1s and 7R$^+$

514 ILC1s in inflammatory conditions, CD45.2 WT mice were injected with indicated G1-ILC

515 populations labeled by Cell Proliferation Dye (CPD) eFluor 450 (Thermo Fisher Scientific)

516 (day 0) followed by the administration of 2 μg IL-15/IL-15Rα at day 1, 3, and 5. After 7 days,

517 liver leukocytes of recipient mice were analyzed.

518

Immunofluorescence

520 Whole FL of WT mice or hepatic lobes of adult CXCR6-GFP KI mice were fixed with 4%

521 paraformaldehyde (PFA) at 4℃ for 6 hours, embedded in Optimal Cutting Temperature

522 compound (Sakura Finetechnical, Tokyo, Japan), and sliced with a cryomicrotome (Leica

523 CM3050S, Wetzlar, Germany). Tissue sections were stained at room temperature for 1 hour

524 with primary antibodies as follows: biotin-anti-CD31, rabbit polyclonal IgG anti-LYVE-1

525 (RELIATech, Braunschweig, Germany), and goat polyclonal IgG anti-NKp46 (R&D,

526 Minneapolis, MN, USA). Following secondary antibodies (BioLegend) were used: Dylight

527 488 anti-rabbit IgG, Alexa Fluor 555 anti-rabbit IgG, Alexa Fluor 647 anti-goat IgG, Brilliant

528 Violet 421 anti-rabbit IgG, Dylight 649 anti-rat IgG, and PE anti-rat IgG. Biotinylated

17

antibodies were detected with FITC-, PE-, or Brilliant Violet 421-conjugated streptavidin (Thermo Fisher Scientific). Stained sections were then mounted using PermaFluor Aqueous Mounting Medium (Thermo Fisher Scientific) and examined by a TCS SP8 confocal microscope (Leica) with HC PLAPO CS2 20×/0.75 IMM or HC PLAPO CS2 40×/1.30 OIL object lenses. Multiple image stacks (10–20 μm) were acquired with two times of frame averaging and maximum projection was then performed on using LAS X software (Leica).

Intravascular staining

PE/Cy7 anti-CD45.2 antibody (clone: 104) (2 μg) was injected intravenously (i.v.) into mice 2 min before the perfusion and liver dissection. Isolated liver leukocytes were stained with fluorophore-conjugated antibodies of interest in addition to APC/Cy7 anti-CD45 antibody (clone: 30-F11) and analyzed by flow cytometry.

Parabiosis

Female CD45.1 and CD45.2 congenic C57BL/6J mice were surgically conjoined as previously described (Gasteiger et al., 2015). In brief, lateral skin from elbow to knee of each mouse was sutured, forelimbs and hindlimbs were tied together, and the skin incisions were closed using surgical adhesive. After 60 days of surgery, mice were analyzed by flow cytometry.

***In vitro* killing assay**

Hepa1-6 cells were purchased from RIKEN BioResource Center (RIKEN BRC, Tsukuba, Japan). B16F10 cells were provided by Dr. T. Honjo at Kyoto University. These mouse tumor cell lines were maintained in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% FBS, 2 mM L-glutamine, and antibiotics. For time-lapse killing assays, 2×10^2 Hepa1-6 cells or B16F10 cells were labeled by CPD eFluor 450 and pre-incubated with RPMI 1640 medium (without phenol red) containing 10% FBS, 10 mM HEPES (pH7.4), antibiotics, and 1 μg/mL PI on 96-well round bottom plates. Freshly sorted liver NK cells, 7R$^-$ ILC1s, or 7R$^+$ ILC1s (2×10^3 cells) were added to the plates and co-cultured with tumor cells. Time-lapse imaging was performed using a BZ-X710 microscope (Keyence, Osaka, Japan) with CFI Plan Apo λ 10× and CFI Plan Fluor DL 10× objective lenses at a 20 min interval for up to 6 hours. To determine the contribution of effector molecules, 50 nM concanamycin A (CMA), 10 μg/mL anti-TRAIL antibody (N2B2), or 10 μg/mL anti-FasL antibody (MFL3)

18

562   were supplemented and compared to vehicle-supplemented controls. Tumor cell viability was

563   defined by the ratio of the CPD$^+$PI$^-$ viable tumor cell number at each time point to the viable

564   tumor cell number at the beginning of the imaging and represented as the moving average of

565   three consecutive time points. Image analysis and cell counts were performed using BZ-X

566   Analyzer (Keyence). For killing assay of YAC-1 cells (provided by Dr. M. Hattori at Kyoto

567   University), 2×10^4 freshly sorted liver NK cells, 7R$^-$ ILC1s, or 7R$^+$ ILC1s were co-cultured

568   for 4 hours with 2×10^3 CPD eFluor 450-labeled YAC-1 cells in RPMI 1640 medium

569   containing 10% FBS, 10 mM HEPES (pH7.4), and antibiotics. After culture, YAC-1 cells

570   were stained with FITC-conjugated Annexin V and PI (MEBCYTO-Apoptosis Kit, MBL) and

571   the ratio of Annexin V$^+$PI$^+$ apoptotic cells were analyzed by flow cytometry.

572

Statistical analysis

573

574   Statistical differences were evaluated by the two-tailed unpaired Student's *t*-test and one-way

575   or two-way analysis of variance (ANOVA) using GraphPad Prism 8 (GraphPad Software, San

576   Diego, California, USA). Asterisks in all figures indicate as follows: *$p < 0.05$, **$p < 0.01$,

577   ***$p < 0.001$, and ****$p < 0.0001$.

578

Author contributions: T.A., S.A., G.C., and K.I. designed the research. T.A., S.A., G.C., A.S., and K.O. performed the animal experiments, flow cytometry, and analyzed the data. T.N., A.S., and M.M. designed and supervised fate-mapping studies. H.M. and S.K. performed the surgery of parabiosis and cesarean section of mice. J.D. contributed to *in vivo* stimulation experiments using IL-15/IL-15Rα. H.O. supported immunofluorescence experiments. T.A. and K.I. wrote the manuscript. All authors read and approved the final version of the manuscript.

Competing interests

All authors declare no competing interests.

Data availability

All data needed to evaluate the conclusions in the paper are present in the paper. RNA-seq data generated in this study are deposited in Gene Expression Omnibus (GEO) under accession code GSE205894.

805

806   **Figures**
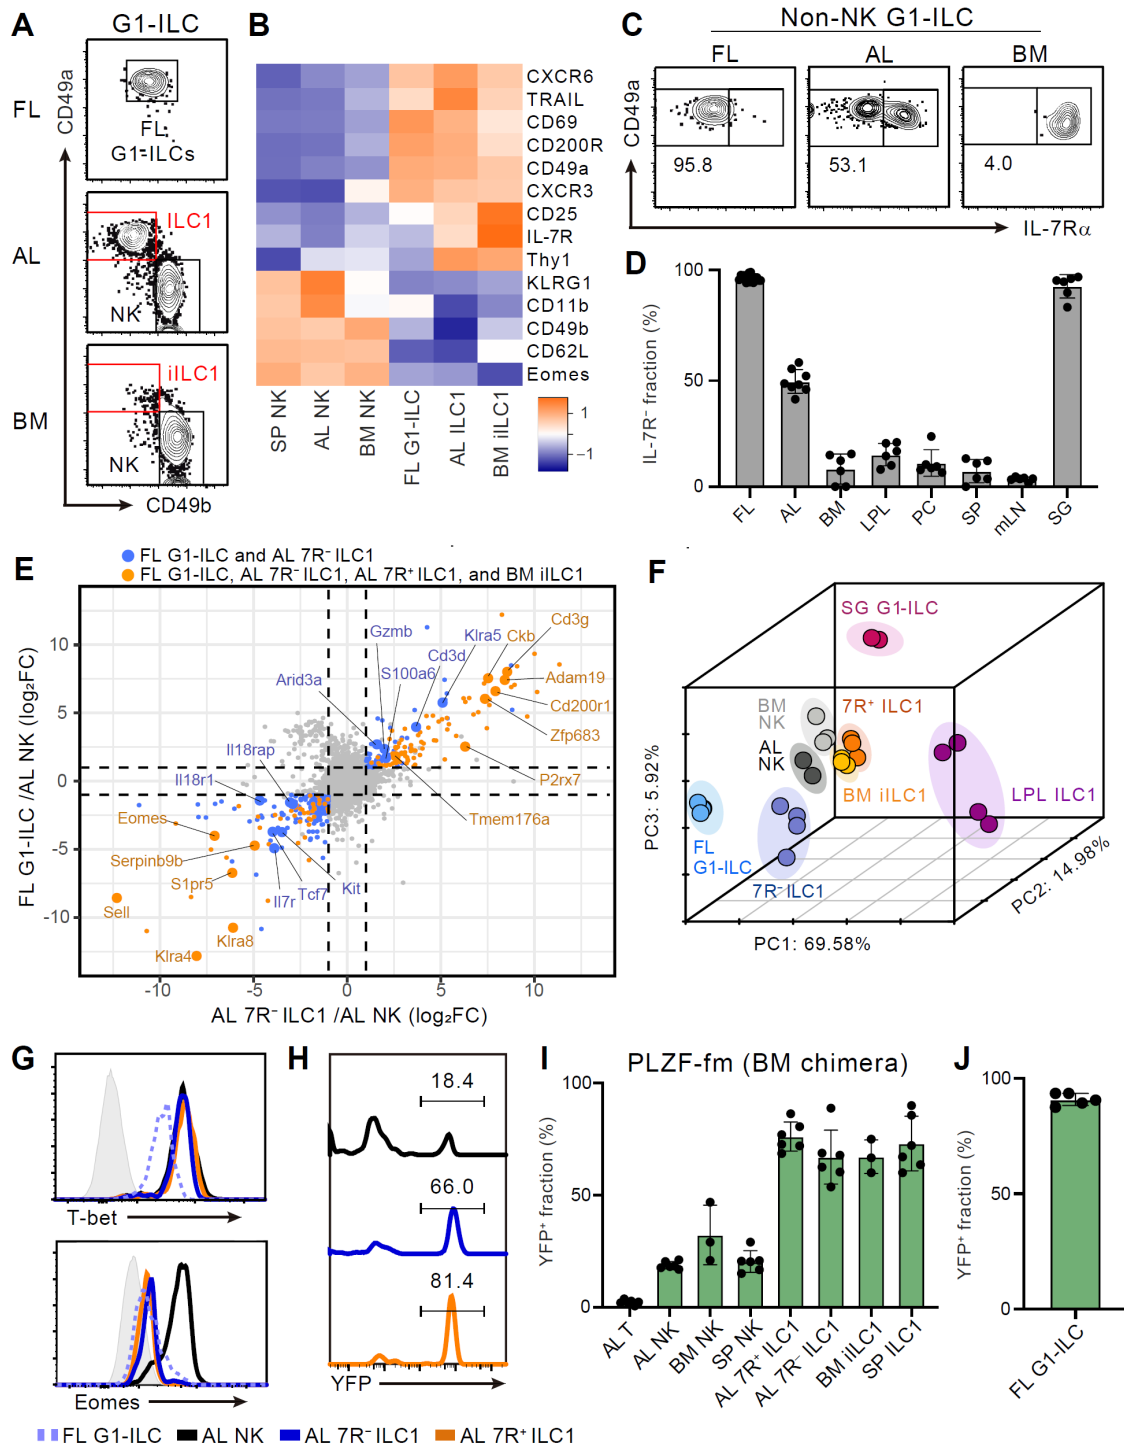

807   **Figure 1. Fetal and adult liver contain *bona fide* ILC1s lacking IL-7R.**

808   (A) Gating strategy of subpopulations of G1-ILCs (CD3⁻NK1.1⁺NKp46⁺) in the E18.5 fetal

809   liver (FL), adult liver (AL), and bone marrow (BM). iILC1, immature ILC1.

810   (B) Heatmap representing log2 transformed mean fluorescence intensity (MFI) of indicated

811   protein expression normalized by z-score transformations. SP, spleen.

28

812 (C) Expression of IL-7Rα on G1-ILCs except for CD49a⁻CD49b⁺ NK cells (non-NK G1-

813 ILCs) in FL, AL, and BM.

814 (D) The percentages of IL-7R⁻ fractions in non-NK G1-ILCs in the indicated tissues ($n = 6$–

815 8). LPL, small intestinal lamina propria lymphocytes; PC, peritoneal cavity; mLN, mesenteric

816 lymph node; SG, salivary gland.

817 (E) Scatter plot showing relative gene expression of FL G1-ILCs and AL 7R⁻ ILC1s

818 compared to AL NK cells in RNA-seq. Genes differentially expressed by FL G1-ILCs, AL

819 7R⁻ ILC1s, AL 7R⁺ ILC1s, and BM iILC1s (orange) or only by FL G1-ILCs and AL 7R⁻

820 ILC1s (blue) compared to AL NK cells are highlighted. FC, fold change.

821 (F) First three principal components in PCA of top 3,000 variant genes.

822 (G) Expression of T-bet (upper) and Eomes (lower) on FL G1-ILCs as well as NK cells, 7R⁻

823 ILC1s, and 7R⁺ ILC1s in AL. Shaded histograms (grey) indicate isotype controls.

824 (H and I) Fate-mapping analysis of adult chimeric mice reconstituted with BM

825 YFP⁻Lin⁻Sca1⁺c-Kit⁺ (LSK) cells from PLZF-GFP-Cre Rosa26-YFP (PLZF-fm) mice.

826 Representative histograms of YFP expression (H) and the percentages of YFP⁺ cells in

827 indicated cell populations (I) are shown ($n = 3$–6).

828 (J) The percentage of YFP⁺ cells in FL G1-ILCs in E18.5 straight PLZF-fm mice ($n = 5$).

829 Data represent at least two independent experiments (A, C, G, and H), are from three to six

830 biological replicates (B), or are pooled from one (J) or multiple (D and I) independent

831 experiments. RNA-seq data are from two (AL NK cells and SG G1-ILCs), three (AL 7R⁺

832 ILC1s, BM iILC1s, and BM NK cells), and four (FL G1-ILCs, AL 7R⁻ ILC1s, and LPL

833 ILC1s) biological replicates (E and F). Data are presented as mean ± SD.

834
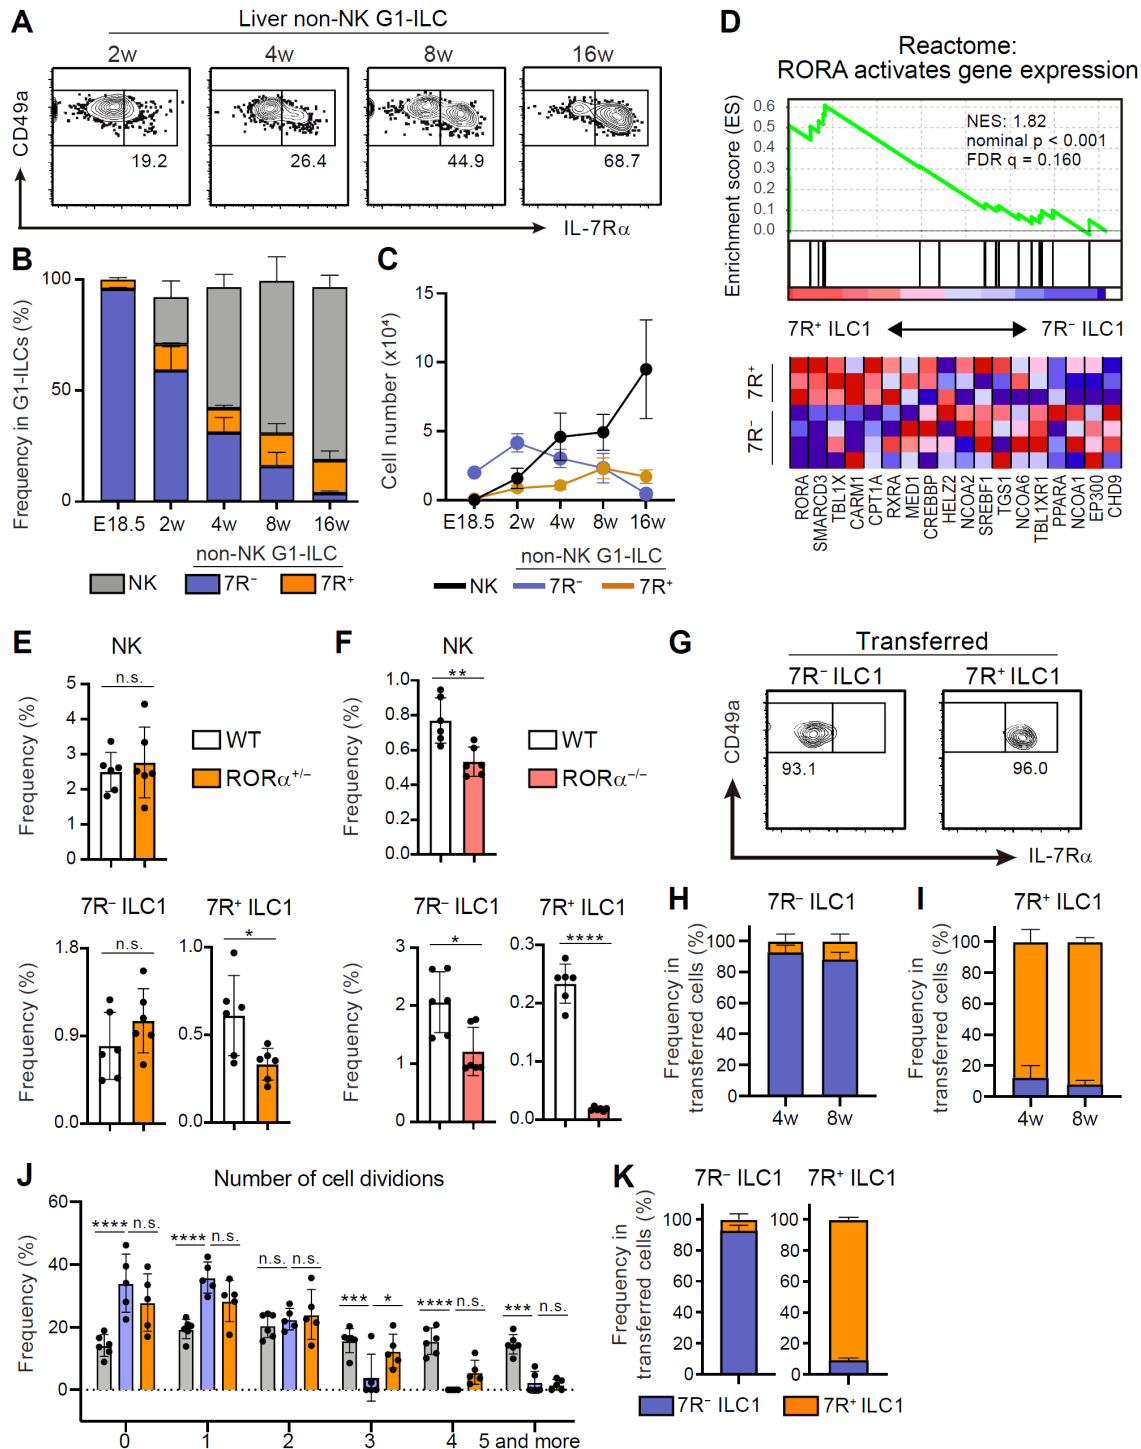

Figure 2. 7R⁺ ILC1s are dispensable for the development of 7R⁻ ILC1s in AL.

(A–C) Kinetics of IL-7Rα expression on liver non-NK G1-ILCs with age. Representative FCM profiles (A), the percentages within G1-ILCs (B), and the cell number (C) are shown (*n* = 5–11 for each timepoint).

(D) GSEA of transcriptomes in 7R⁺ ILC1s compared to 7R⁻ ILC1s. Eighteen genes included in an indicated gene set from Reactome Pathway are shown. The lower heatmap shows

841   relative gene expression levels in AL $7R^-$ and $7R^+$ ILC1s.

842   (E) The percentages of AL G1-ILC populations in control or $ROR\alpha^{+/-}$ mice ($n = 6$).

843   (F) The percentages of AL G1-ILC populations in control or $ROR\alpha^{-/-}$ mice ($n = 6$).

844   (G–I) Flow cytometric (FCM) analysis of transferred AL $7R^-$ and $7R^+$ ILC1s detected in the

845   host liver at 4 weeks and 8 weeks post-transfer. Representative FCM profiles (G) and the

846   percentages of the fate of transferred $7R^-$ ILC1s (H) and $7R^+$ ILC1s (I) are shown ($n = 3$–6).

847   (J) Host mice received with CPD-eFluor 450-labeled $7R^-$ and $7R^+$ ILC1s are repeatedly

848   stimulated with i.p. injection of IL-15/IL-15Rα complex. The number of transferred cell

849   division based on the FCM analysis of CPD-eFluor 450 dye dilution ($n = 5$–6) are shown.

850   (K) The percentages of the fate of transferred AL $7R^-$ ILC1s and $7R^+$ ILC1s detected in the

851   liver of host mice injected with IL-15/IL-15Rα complex ($n = 5$–6).

852   Data are from three (AL $7R^+$ ILC1s) and four (AL $7R^-$ ILC1s) biological replicates (D),

853   represent at least two independent experiments (A and G), or are pooled from one (F) and

854   multiple (B, C, E, H–K) independent experiments. Data are presented as mean ± SD. $*p <$

855   0.05, $**p < 0.01$, $***p < 0.001$, $****p < 0.0001$.

856

31
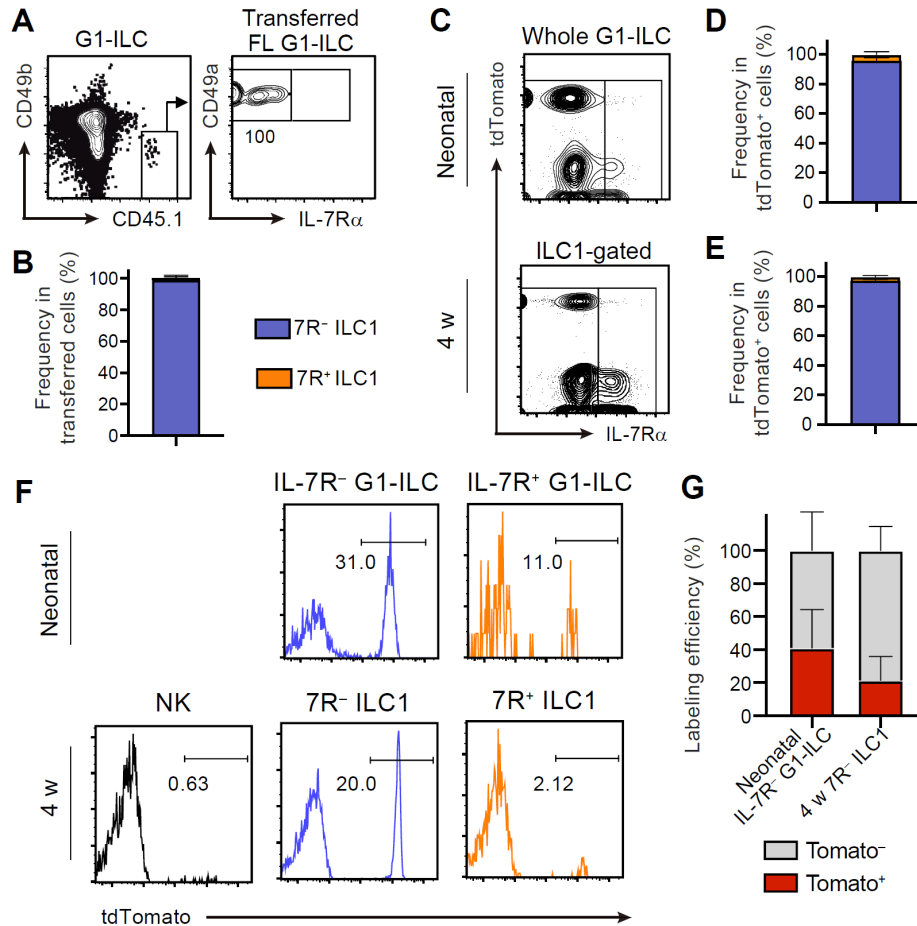

Figure 3. FL G1-ILCs exclusively give rise to 7R⁻ ILC1s.

(A and B) FCM analysis of transferred FL G1-ILCs (CD45.1) detected in the host liver (CD45.2) at 4 weeks post-transfer. Representative FCM profiles (A) and the percentages of transferred cell fate (B) are shown ($n = 4$).

(C–E) FCM analysis of tdTomato$^+$ cells in neonatal and adult NKp46-CreERT2 Rosa26-tdTomato mice treated with tamoxifen at E17.5. Representative FCM plots (C) and the percentage of the fate of tdTomato$^+$ cells in neonates (D; $n = 10$) and 4 weeks old mice (E; $n = 5$) are shown. Blue, IL-7R$^-$ fraction; orange, IL-7R$^+$ fraction.

(F and G) FCM analysis of tdTomato expression on indicated G1-ILC populations in NKp46-Cre Rosa26-tdTomato mice treated with tamoxifen at E17.5. Representative histograms (F) and the percentages of tdTomato$^+$ and tdTomato$^-$ fractions in neonatal IL-7R$^-$ G1-ILCs and 7R$^-$ ILC1s in 4 weeks old mice (G) are shown ($n = 5$–10).

Data represent at least two independent experiments (A, C, and F). Data are pooled from multiple independent experiments (B, D, E, and G) and presented as mean ± SD.
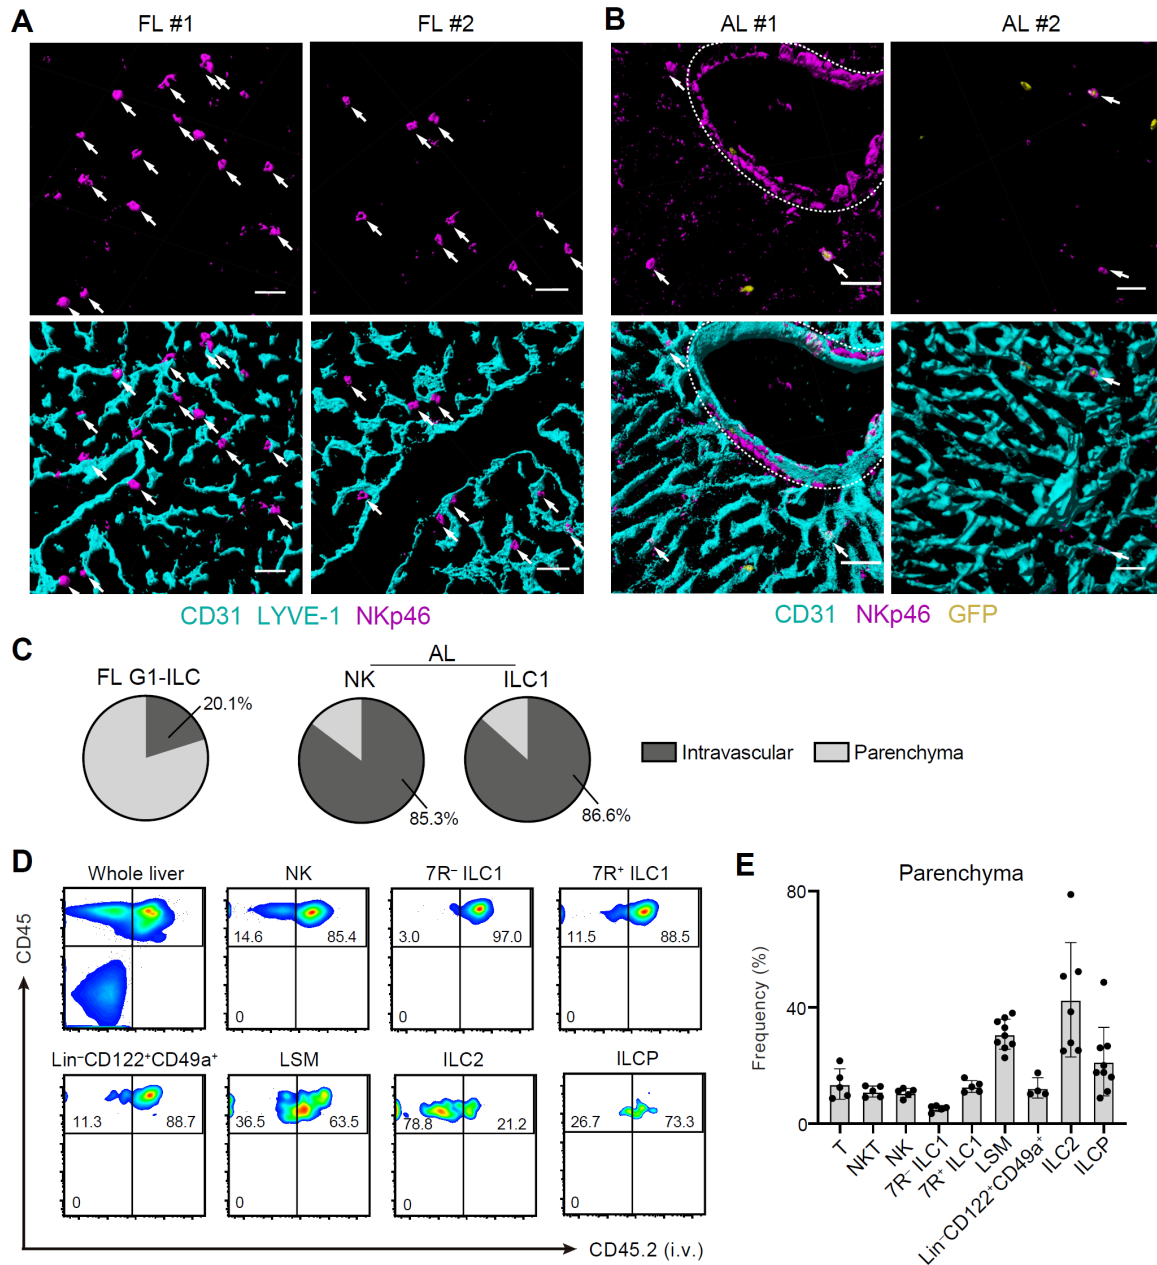

32

Figure 4. Liver G1-ILCs shift distributions from parenchyma to sinusoids during development.

(A and B) 3D-reconstructed immunofluorescence images of frozen sections of FL from WT mice (A) and AL from CXCR6$^{GFP/+}$ mice (B) stained with anti-NKp46 (magenta) and anti-CD31 and/or anti-LYVE-1 (for FL endothelium) (cyan) antibodies. GFP signals are shown in yellow. White arrows indicate G1-ILCs. Hepatic artery is circled by a dotted line. Scale bar, 40 μm.

(C) The percentages of indicated G1-ILC subsets localized inside (intravascular) or outside (parenchyma) of the blood vessels. Data represent randomly counted 169 cells for FL G1-ILCs pooled from four E18.5 WT mice and 232 cells for AL NK cells as well as 136 cells for

33

882   AL ILC1s pooled from four CXCR6$^{GFP/+}$ mice.

883   (D and E) FCM analysis of AL of mice injected i.v. with PE/Cy7 anti-CD45.2 antibody 2 min

884   before the liver perfusion and leukocyte isolation. Representative FCM profiles (D) and the

885   percentages of cells unlabeled by i.v. CD45.2 staining within CD45$^+$ cells (considered as

886   parenchyma-distributed cells) (E) are shown (n = 4–9).

887   Data represent four mice (A and B) or at least two independent experiments (D). Data are

888   pooled from multiple independent experiments (C and E) and presented as mean ± SD.

889
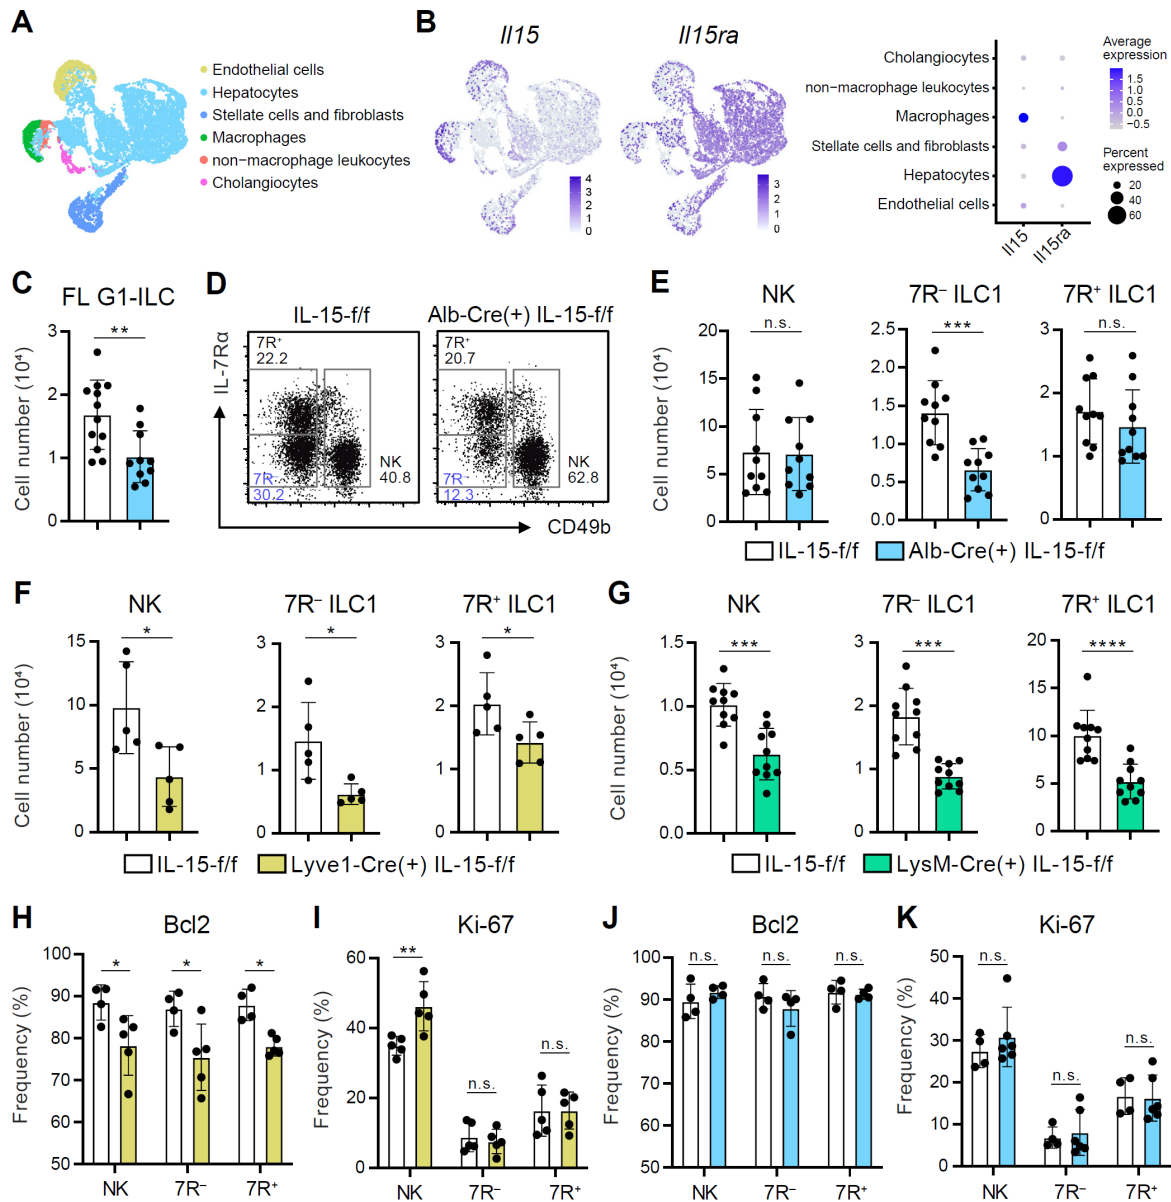

Figure 5. Hepatocytes provide the parenchymal IL-15 niche regulating the local development of 7R⁻ ILC1s.

(A and B) Single nuclei RNA-seq (snRNA-seq) analysis of mouse whole liver cells (Liver Cell Atlas; www.livercellatlas.org). UMAP visualization (A) and expression levels of *Il15* and *Il15ra* (B) in each cell population assigned in Figure 5–figure supplement 1B are shown.

(C) The cell number of FL G1-ILCs in control or IL-15$^{\text{Alb-Cre}}$ mice ($n = 10–12$).

(D and E) FCM analysis of AL G1-ILCs in control or IL-15$^{\text{Alb-Cre}}$ mice. Representative FCM plots (D) and the cell number of each population (E) are shown ($n = 10$).

(F and G) The cell number of indicated G1-ILC populations in IL-15$^{\text{Lyve1-Cre}}$ mice (F; $n = 5$) or IL-15$^{\text{LysM-Cre}}$ mice (G; $n = 10$) compared to controls.

(H and I) The percentages of Bcl-2 (H; $n = 4–5$) and Ki-67 (I; $n = 5$) expressing cells within

35

901   each G1-ILC population in control or IL-15$^{\text{Lyve1-Cre}}$ mice.

902   (J and K) The percentages of Bcl-2 (J; $n = 4$) and Ki-67 (K; $n = 4$–6) expressing cells within

903   each G1-ILC population in control or IL-15$^{\text{Alb-Cre}}$ mice.

904   Data represent three independent experiments (D) or are pooled from multiple independent

905   experiments (C and E–K) and presented as mean ± SD. $*p < 0.05$, $**p < 0.01$, $***p < 0.001$,

906    $****p < 0.0001$.

907
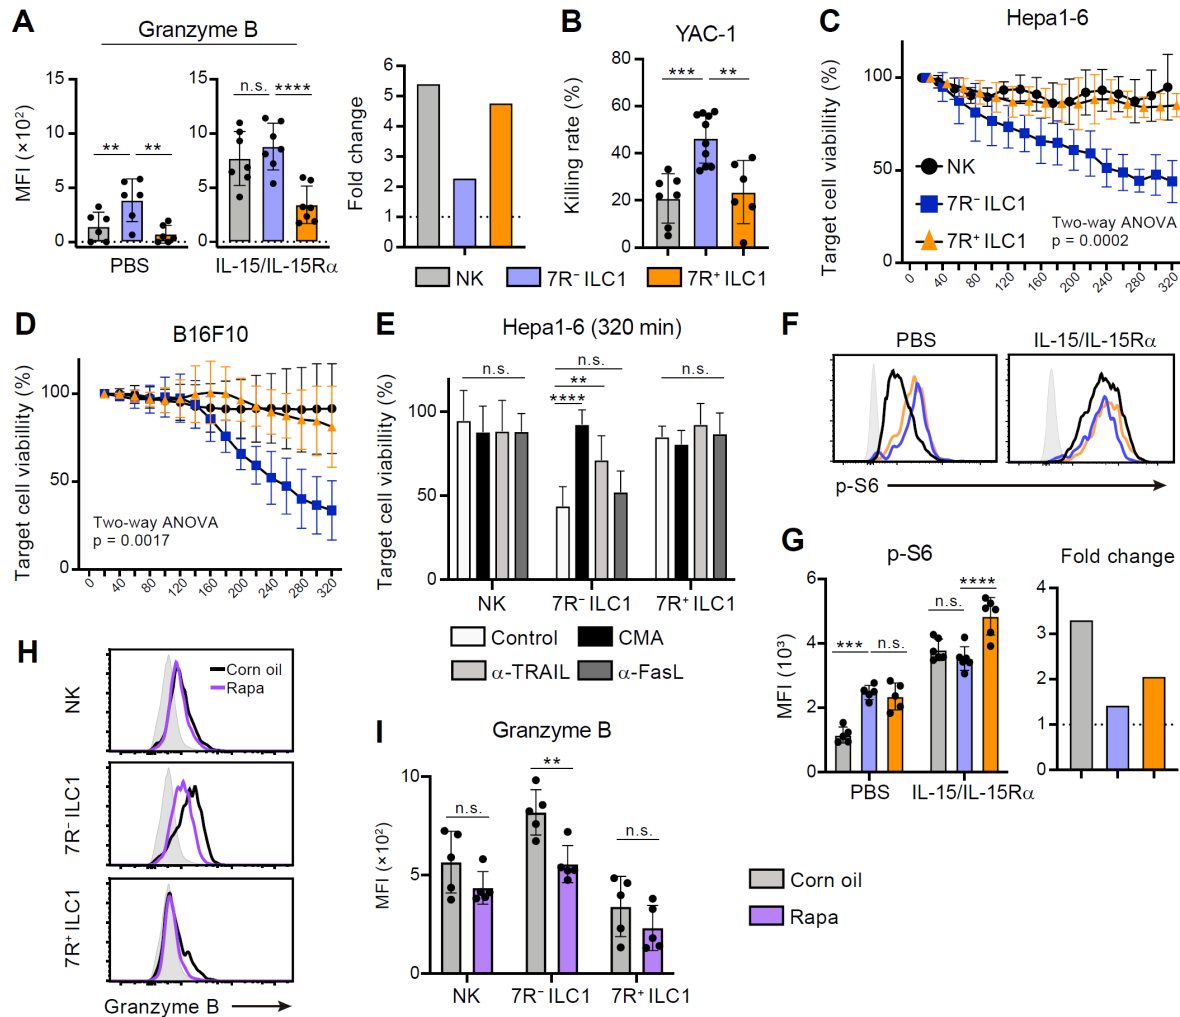

Figure 6. 7R⁻ ILC1s exhibit cytotoxicity via granzyme B expression underpinned by steady-state mTOR activation.

(A) Granzyme B expression on each AL G1-ILC population in control or IL-15/IL-15Rα-treated mice. MFI (left) and its fold change after the IL-15/IL-15Rα treatments (right) are shown (n = 6–7).

(B) The percentages of annexin V⁺PI⁺ YAC-1 cells in flow-based cytotoxicity assays. Freshly isolated effector cells were co-cultured with target cells for 4 hours (E:T ratio = 10:1) (n = 6–10).

(C and D) Target cell viability at each timepoint in time-lapse cytotoxicity assay using Hepa1-6 cells (C; n = 6) and B16F10 cells (D; n = 7–8) as target cells. Freshly isolated effector cells were co-cultured with target cells up to 6 hours (E:T ratio = 10:1).

(E) Hepa1-6 cell viability at 320 min in time-lapse cytotoxicity assays supplemented with concanamycin A (CMA) or neutralizing antibody for TRAIL (α-TRAIL) or FasL (α-FasL) compared to vehicle-supplemented controls (n = 6).

37

922   (F and G) FCM analysis of phosphorylation of S6 in NK cells (black), 7R$^-$ ILC1s (blue), and

923   7R$^+$ ILC1s (orange) in control or IL-15/IL-15Rα-treated mice. Representative histograms (F)

924   and MFI (left) and its fold change after the IL-15/IL-15Rα treatments (right) (G) are shown (n

925   = 5–6). Shaded histograms (grey) indicate isotype controls.

926   (H and I) FCM analysis of granzyme B expressed on each AL G1-ILC population in control

927   or rapamycin-treated mice. Representative histograms (H) and MFI (I) are shown (n = 5).

928   Shaded histograms (grey) indicate isotype controls.

929   Data represent at least two independent experiments (F and H) or are pooled from multiple

930   independent experiments (A–E, G, and I) and are presented as mean ± SD. **$p < 0.01$, ***$p <$

931   0.001, ****$p < 0.0001$.

932

933

934   **Figure Supplements**
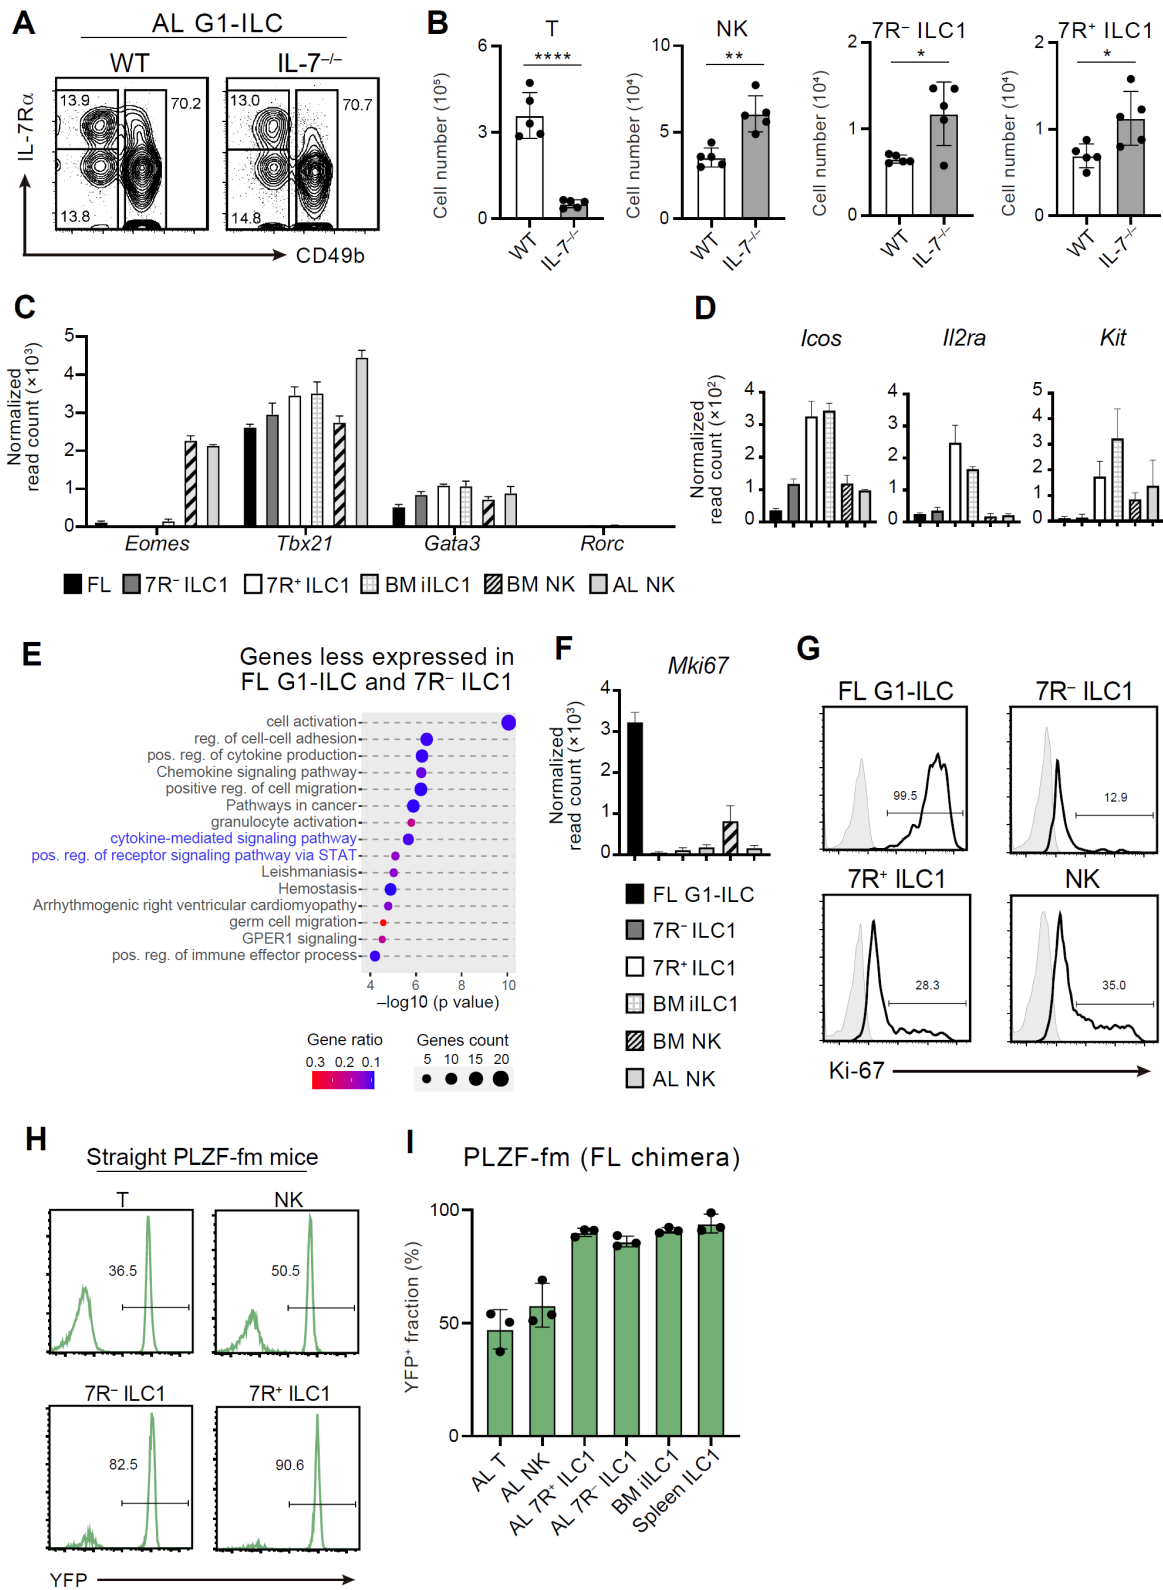

935   **Figure 1–figure supplement 1. Characterization of fetal and adult G1-ILC identities.**

936   (A and B) Flow cytometry (FCM) analysis of AL lymphocytes in control or IL-7$^{-/-}$ mice.

39

937 Representative FCM profiles of G1-ILCs (A) and the cell number of each cell population (B)

938 are shown ($n = 5$).

939 (C) Normalized read counts of *Eomes*, *Tbx21*, *Gata3*, and *Rorc* expressed on each G1-ILC

940 population in FL, AL, and BM obtained from RNA-seq.

941 (D) Normalized read counts of *Icos*, *Il2ra*, and *Kit* expressed on each G1-ILC population.

942 (E) Dot plots showing the significantly enriched pathways on DEGs less expressed in FL G1-

943 ILCs and 7R$^-$ ILC1s but not in 7R$^+$ ILC1s and BM iILC1s compared to AL NK cells,

944 analyzed by Metascape. Gene ratio indicates the ratio of the gene number corresponding to

945 the DEGs in the pathway (gene count) to the total gene number in the pathway. Pathways

946 related to cytokine responses were highlighted (blue).

947 (F) Normalized read counts of *Mki67* expressed on each G1-ILC population obtained from

948 RNA-seq.

949 (G) Expression of Ki-67 protein on FL G1-ILCs as well as NK cells, 7R$^-$ ILC1s, and 7R$^+$

950 ILC1s in AL.

951 (H) Representative histograms of YFP expression in AL lymphocyte populations of straight

952 PLZF-GFP-Cre Rosa26-YFP (PLZF-fm) mice ($n = 2$).

953 (I) Fate-mapping analysis of adult chimeric mice reconstituted with FL YFP$^-$ LSK cells from

954 PLZF-fm mice. The percentages of YFP$^+$ cells in indicated cell populations are shown ($n = 3$).

955 Data are from two (AL NK cells), three (AL 7R$^+$ ILC1s, BM iILC1s, and BM NK cells), and

956 four (FL G1-ILCs and AL 7R$^-$ ILC1s) biological replicates (C–F). Data represent one (H and

957 I) or two (A and G) independent experiments or pooled from multiple independent

958 experiments (B). Data are presented as mean ± SD. *$p < 0.05$, **$p < 0.01$, ****$p < 0.0001$.

959
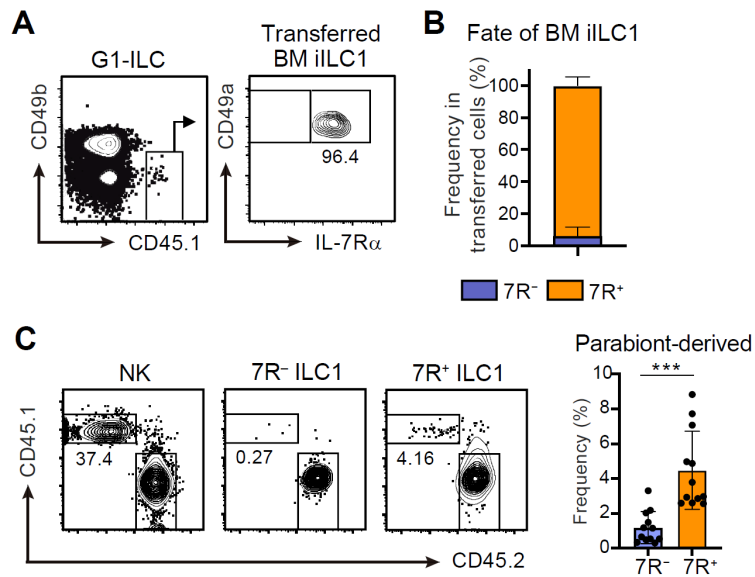

**Figure 2–figure supplement 1. BM iILC1s have ability to give rise to AL 7R$^+$ ILC1s *in vivo*.**

(A and B) FCM analysis of transferred BM iILC1s (CD45.1) detected in the host liver (CD45.2) at 4 weeks post-transfer. Representative FCM profiles (A) and the percentages of transferred cell fate (B) are shown ($n = 6$).

(C) FCM analysis of AL G1-ILCs in CD45.2 WT mice conjoined with CD45.1 WT mice in parabiosis experiments. Representative FCM profiles and the percentages of parabiont-derived cells in AL 7R$^-$ and 7R$^+$ ILC1s are shown ($n = 12$).

Data represent at least two independent experiments (A and C), or are pooled from multiple independent experiments (B and C). Data are presented as mean ± SD. ***$p < 0.001$.

Figure 3–figure supplement 1. FL G1-ILCs contribute to AL 7R⁻ ILC1 pool.

(A) FCM analysis of tdTomato$^+$ cells in AL of NKp46-CreERT2 Rosa26-tdTomato mice treated with tamoxifen at E17.5. Representative FCM plots in neonates (n = 10) and 4 weeks old mice (n = 5) are shown.

(B–D) FCM analysis of Ly-49E/F expression on 7R⁻ ILC1s. Representative histograms (D) and the percentages of Ly-49E/F$^+$ and Ly-49E/F$^-$ fraction in whole 7R⁻ ILC1s (C) or in tdTomato$^+$ 7R⁻ ILC1s (D) are shown (n = 5).

Data represent at least two independent experiments (A and B) or are pooled from multiple independent experiments (C and D). Data are presented as mean ± SD.
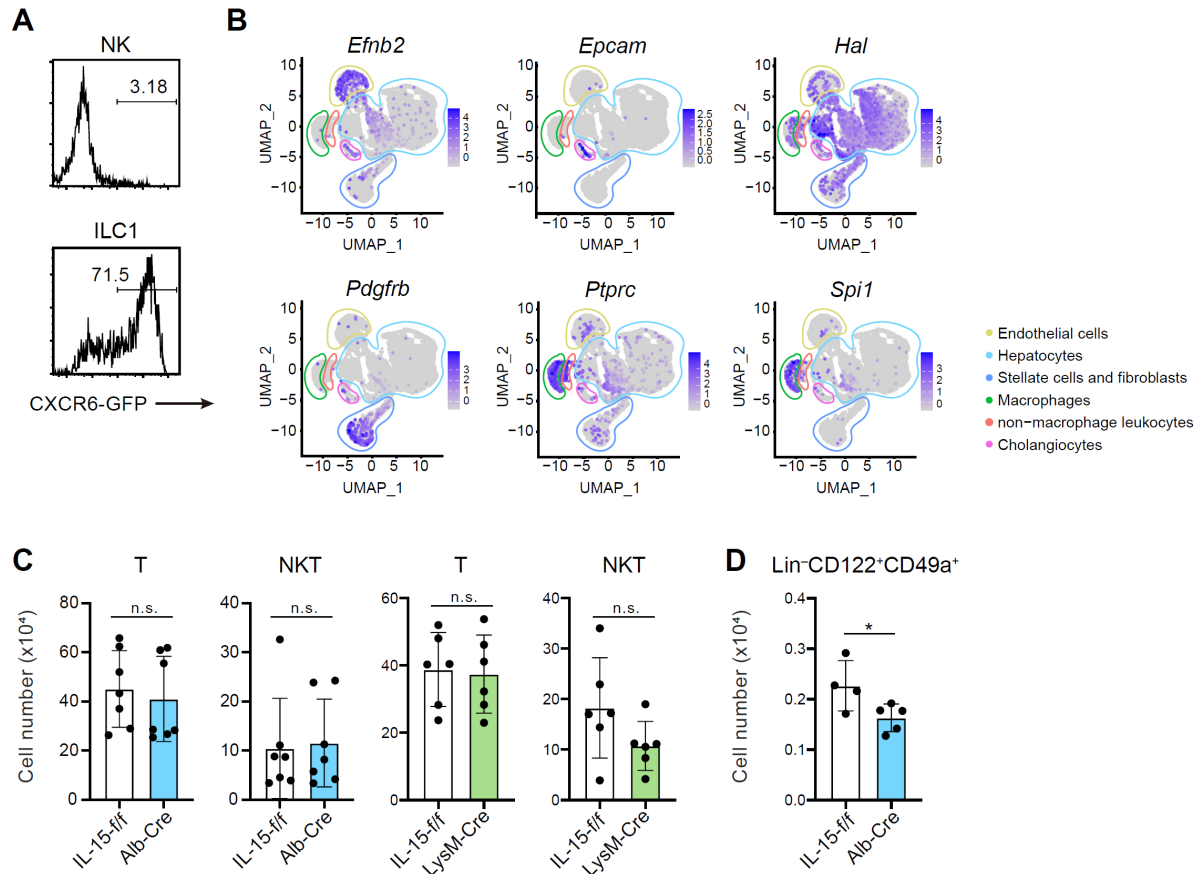

Figure 5–figure supplement 1. Liver IL-15-producing cells supports lymphoid cells in a subset-dependent manner.

(A) Expression of GFP on AL NK cells and ILC1s in CXCR6$^{GFP/+}$ mice.

(B) UMAP visualization of snRNA-seq analysis of mouse whole liver cells (Liver Cell Atlas; www.livercellatlas.org). Cell identity of each cluster was defined based on the expression of *Efnb2*, *Epcam*, *Hal*, *Pdgfb*, *Ptprc*, and *Spi1*.

(C) The cell number of AL T cells and CD3$^+$NK1.1$^+$ (NKT) cells in control, IL-15$^{Alb-Cre}$ mice, or IL-15$^{LysM-Cre}$ mice ($n = 6–7$).

(D) The cell number of Lin$^-$CD122$^+$CD49a$^+$ cells in control or IL-15$^{Alb-Cre}$ mice ($n = 4–5$).

Data represent two independent experiments (A) or are pooled from multiple independent experiments (C and D) and presented as mean ± SD. $^*p < 0.05$.
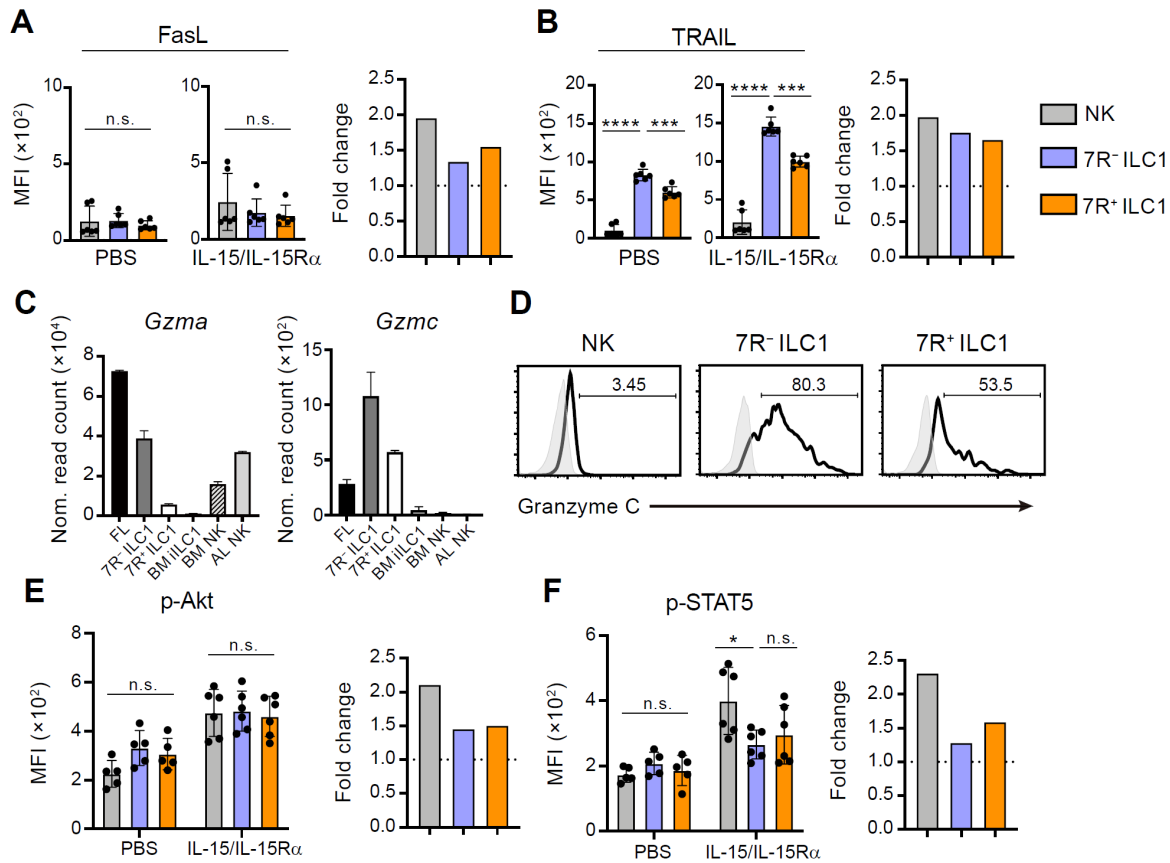

43

Figure 6–figure supplement 1. Differential effector molecule expression and cytokine responsiveness among heterogenous G1-ILC subsets.

(A and B) Expression of FasL (A) and TRAIL (B) on each AL G1-ILC population in control or IL-15/IL-15Rα-treated mice ($n = 6$). MFI (left) and its fold change after the IL-15/IL-15Rα treatments (right) are shown.

(C) Normalized read counts of *Gzma* and *Gzmc* expressed on each G1-ILC population obtained from RNA-seq.

(D) Expression of granzyme C protein on NK cells, 7R⁻ ILC1s, and 7R⁺ ILC1s in AL.

(E and F) Phosphorylation levels of Akt (E) and STAT5 (F) on each AL G1-ILC population in control or IL-15/IL-15Rα-treated mice ($n = 5$–6). MFI (left) and its fold change after the IL-15/IL-15Rα treatments (right) are shown.

Data are from two (AL NK cells), three (AL 7R⁺ ILC1s, BM iILC1s, and BM NK cells), and four (FL G1-ILCs and AL 7R⁻ ILC1s) biological replicates (C). Data represent two independent experiments (D) or are pooled from multiple independent experiments (A, B, E, and F) and presented as mean ± SD. *$p < 0.05$, ***$p < 0.001$, ****$p < 0.0001$.
