Dominici et al.,

Abstract

In skeletal muscle, muscle stem cells (MuSC) are the main cells responsible for regeneration upon injury. In diseased skeletal muscle, it would be therapeutically advantageous to replace defective MuSCs, or rejuvenate them with drugs to enhance their self-renewal and ensure long-term regenerative potential. One limitation of the replacement approach has been the inability to efficiently expand MuSCs *ex vivo,* while maintaining their stemness and engraftment abilities. Herein, we show that inhibition of type I protein arginine methyltransferases (PRMTs) with MS023 increases the proliferative capacity of *ex vivo* cultured MuSCs. Single cell RNA sequencing (scRNAseq) of *ex vivo* cultured MuSCs revealed the emergence of subpopulations in MS023-treated cells which are defined by elevated Pax7 expression and markers of MuSC quiescence, both features of enhanced self-renewal. Furthermore, the scRNAseq identified MS023-specific subpopulations to be metabolically altered with upregulated glycolysis and oxidative phosphorylation (OxPhos). Transplantation of MuSCs treated with MS023 had a better ability to repopulate the MuSC niche and contributed efficiently to muscle regeneration following injury. Interestingly, the preclinical mouse model of Duchenne muscular dystrophy had increased grip strength with MS023 treatment. Our findings show that inhibition of type I PRMTs increased the proliferation capabilities of MuSCs with altered cellular metabolism, while maintaining their stem-like properties such as self-renewal and engraftment potential.

Dominici et al.,

Introduction

Muscle stem cells (MuSCs) reside on the periphery of muscle fibers in skeletal muscle and are activated following injury to drive muscle regeneration (Lepper *et al*, 2011; Relaix & Zammit, 2012). Major challenges arise when attempting to manipulate MuSCs *ex vivo*. Purified MuSCs spontaneously differentiate upon *ex vivo* expansion (Fu *et al*, 2015a; Sacco *et al*, 2008), limiting the potential of CRISPR Cas9-based applications and stem cell engraftment therapy. It is known that *ex vivo* cultured MuSCs are vastly inferior at engrafting and contributing to muscle regeneration compared to freshly isolated MuSCs, indicating the importance of retaining stemness for MuSC engraftment and muscle regeneration (Montarras *et al*, 2005; Sakai *et al*, 2017). Cell-intrinsic defects in patients with Duchenne muscular dystrophy (DMD) prevent MuSCs from maintaining a proper balance between stem cell self-renewal and differentiation, ultimately leading to depletion of regeneration-competent MuSCs (Bentzinger *et al*, 2014; Dumont *et al*, 2015; Wang *et al*, 2013).

MuSCs have metabolic flexibility that allows them to adapt to demands presented by their changing environments (Relaix *et al*, 2021). Indeed, metabolic signatures are strong contributors to the heterogeneity observed in isolated MuSCs (Cho & Doles, 2017). Several findings have indicated that the metabolic state of MuSCs is inextricably tied to their function and fate. Quiescent MuSCs predominantly rely on fatty acid oxidation (FAO) and oxidative phosphorylation (OxPhos) (Machado *et al*, 2017; Ryall *et al*, 2015). While glycolysis remains low in quiescent cells, it is upregulated as MuSCs begin to proliferate following activation, representing a metabolic shift in activated MuSCs (L'Honore *et al*, 2018; Ryall *et al.*, 2015). The dynamic regulation of metabolic state during the transition from MuSC quiescence to proliferation therefore presents a unique avenue to regulate MuSC regenerative capacity.

Dominici et al.,

There is growing evidence to suggest a role for the post-translational modification arginine methylation in muscle cellular metabolism (Blanc & Richard, 2017; Saber & Rudnicki, 2022; vanLieshout & Ljubicic, 2019). Arginine methylation is carried out by 9 protein arginine methyltransferases (PRMTs) (Xu & Richard, 2021). PRMTs are classified according to their catalytic activity: type I enzymes (ex: PRMT1, PRMT2, PRMT3, CARM1, PRMT6 and PRMT8) catalyze arginine asymmetrical dimethylation (ADMA), type II enzymes (ex: PRMT5, PRMT9) catalyze arginine symmetrical dimethylation (SDMA), and the unique type III enzyme PRMT7 catalyzes arginine monomethylation (MMA) (Bedford & Clarke, 2009; Jain & Clarke, 2019). PRMTs methylate many cellular proteins including histones and are known epigenetic regulators (Xu & Richard, 2021).

PRMTs are known regulators of MuSCs. PRMT1-null mouse MuSCs are highly proliferative and can be expanded in culture, but are unable to terminate differentiation, leading to a severe muscle regeneration defect *in vivo* following muscle injury (Blanc *et al*, 2017). CARM1 is a well-known transcriptional coactivator for nuclear receptors and p300/CPB (Bedford & Clarke, 2009) and it is a mediator of skeletal muscle plasticity (Saber & Rudnicki, 2022; vanLieshout & Ljubicic, 2019). CARM1 methylates the myogenic transcription factor, PAX7, to complex with histone methyltransferase complex to allow the expression of myogenic transcription factor Myf5 during asymmetric stem cell divisions (Kawabe *et al*, 2012). CARM1 regulates MuSCs metabolism by methylating AMP-activated protein kinase (AMPK) in MuSCs (Stouth *et al*, 2020). PRMT5 regulates MuSC proliferation by epigenetically downregulating expression of the cell cycle inhibitor p21 and deletion of PRMT5 in MuSCs blocks their expansion *ex vivo* and causes defects in muscle regeneration *in vivo* (Zhang *et al*, 2015). PRMT7 functions in the myogenic process and is required for MuSC self-renewal and muscle

Dominici et al.,

regeneration, as deletion of PRMT7 in MuSCs leads to persistent p21 expression (Blanc *et al*, 2016).

Given the importance in maintaining MuSC stemness and the enhanced MuSC proliferation observed with PRMT1 deficiency (Blanc *et al.*, 2017), we aimed to determine whether the reversible inhibition of type I PRMTs using the MS023 inhibitor (Eram *et al*, 2016) would affect cellular metabolism and fulfil the requirements of generating a stem-like MuSC in culture with subsequent regenerative capabilities. Small molecule inhibitors of epigenetic regulators are a promising avenue to pursue in the treatment of muscle wasting diseases. Indeed, an inhibitor of Setd7-mediated lysine methylation (Judson *et al*, 2018), was shown to have beneficial effects on self-renewal and regeneration.

Herein, we show that MS023, an inhibitor of type I PRMTs, fulfiled the requirements of a reversible inhibitor which maintained the stemness of cultured MuSCs, while allowing for engraftment and regenerative capabilities. Although type I PRMTs have well-known indications as epigenetic modulators, we show that targeting type I PRMTs promoted the proliferation of MuSCs and maintained their self-renewal and ability to engraft.

Results

Type I PRMT inhibitor MS023 enhances self-renewal and *in vitro* expansion of MuSCs

We isolated single muscle fibers from 6- to 8-week-old C57BL/6 mice, cultured them *in vitro* with MS023 or vehicle (DMSO) for 48 h, and stained them for the myogenic transcription factor Pax7 (Seale *et al*, 2000; Soleimani *et al*, 2012), and the proliferation marker ki67. The number of Pax7$^+$/ki67$^+$ cells increased significantly in the presence of MS023 (Eram *et al.*, 2016) for 48 h (Figure 1A, 1B). We observed a significant increase in the number of clusters with 3 or more cells with MS023 treatment (Figure 1B), as observed for PRMT1-deficient MuSCs (Blanc *et al.*, 2017). Treatment with a specific CARM1 inhibitor TP-064 (Nakayama *et al*, 2018) over the course of 6 days did not increase MuSC cell number, ruling out that MS023 increased proliferation was mediated by CARM1 (Figure 1-figure supplements 1A). Moreover, we investigated the expression of other type I PRMTs from publicly available single cell RNAseq datasets (Oprescu *et al*, 2020), which were performed on skeletal muscle at different time points post-cardiotoxin injury (uninjured, and 0.5, 2, 3.5, 5, 10, and 21 days post-injury). Their findings show that PRMT1 is by far the most expressed type I PRMT in MuSCs at every time point tested (Figure 1-figure supplements 1B). CARM1 (PRMT4) is expressed at high level in a small/moderate subset of cells, especially during regeneration. PRMT6 is expressed at low level in a small proportion of cells, while PRMT8 expression was not detected. These findings show that PRMT1 is the predominant type I PRMT1 in MuSCs. Taken together, these data show that type I PRMT inhibition causes *in vitro* MuSC expansion and is likely mediated by the inhibition of PRMT1.

To determine the activation state of these fiber-associated MuSCs, we examined fibers after 48 h in culture for the expression of Pax7 and the myogenic regulator transcription factor,

Dominici et al.,

MyoD (Rudnicki *et al*, 1993; Troy *et al*, 2012). Interestingly, MS023 treatment restricted the proportion of committed Pax7$^-$/MyoD$^+$ cells, while expanding the proportion of activated and cycling cells (Pax7$^+$/MyoD$^+$, Figure 1C, D).

MuSCs spontaneously differentiate into non-cycling myoblasts and lose their stemness *in vitro* (Montarras *et al.*, 2005; Ryall *et al.*, 2015; Sacco *et al.*, 2008). The enhanced proliferation of MuSCs observed with type I PRMT inhibition on muscle fibers prompted us to examine whether similar effects could be achieved with FACS-purified MuSCs cultured *in vitro*. MuSCs incubated with MS023 for 48 h had reduced ADMA containing proteins, as visualized by immunoblotting (Figure 1-figure supplements 1C), and had increased proliferative capacity of MuSCs, as determined by ki67 expression by immunofluorescence and FACS analysis (Figure 1-figure supplements 1D, 1E). These data are consistent with what was observed in muscle fiber-associated MuSCs (Figure 1A-C). Importantly, immunofluorescence analysis of myogenic markers in cultured MuSCs revealed that MS023 treatment prevented initiation of differentiation, as indicated by the significantly reduced sub-population of committed Pax7$^-$/MyoD$^+$ cells compared to control DMSO culture (13% versus 31%, respectively) (Figure 1E, F). Additionally, there was an increase in the proportion of cells that have retained their stemness by delaying expression of MyoD (Pax7$^+$/MyoD$^-$) in the MS023-treated samples compared to DMSO (40% versus 9%, Figure 1E, F). Similar proportions were observed with fiber-associated MuSCs (34% versus 14%, Figure 1C, D). Furthermore, we observed that the impediment of precocious differentiation observed by treatment with MS023 led to enhanced long-term culture capabilities of MuSCs up to the 14th passage (Figure 1-figure supplements 1F). Altogether, these findings indicate that treatment with MS023 maintained cultured MuSCs in a stem-like state.

Dominici et al.,

Transcriptionally distinct MuSC sub-populations emerge under type I PRMT inhibition

To identify subpopulations of MuSCs generated by MS023, we performed single-cell RNA

sequencing (scRNAseq). MuSCs were purified from 8-week-old C57BL/6 mice in biological

duplicates immediately after 1) isolation (termed d0; sample day 0), and 2) culture in growth

medium for 4 days with 0.033% DMSO as control (sample d4) or with 1μM MS023 (sample

d4MS023), and 3) grown in growth media for 6 days with 0.033% DMSO removed at day 4

(sample d6), or 6 days in culture with 1μM MS023 removed at day 4 (sample d6MS023rd4).

Cells were collected at these time points and processed on the 10x Genomics Chromium

platform for scRNAseq. Data filtering and analysis was performed using the Seurat package for

scRNAseq analysis (Butler *et al*, 2018). After filtering out low-quality cells, approximately 4,000

cells (average, 3,887 ± 44 cells) from each sample were retained for subsequent analysis

(Supplementary File 2). A Pearson correlation of >0.98 (Figure 2-figure supplements 1A) was

obtained between replicates and we chose to include a replicate for each time point for analysis.

Dimensionality reduction was performed using uniform manifold approximation and

projection (UMAP) on pooled cells from all samples, resulting in 10 distinct subpopulations of

myogenic cells (labelled 0-9, Figure 2-figure supplements 1B). We then visualized the

distribution of individual samples within the UMAP embedding (Figure 2C, Figure 2-figure

supplements 1C). To determine the identity of the 10 subpopulations, we examined the

expression of *Pax7* and the bHLH transcription factors *Myod1, Myf5* and *Myog* (Figure 2B).

Two populations of *Pax7* and *Myf5* expressing cells were observed that we called

quiescence 1 and 2 (Q1 and Q2), while the two populations that expressed both *Myod1* and *Myog*

were called differentiated myoblasts 1 and 2 (DM1 and DM2, Figure 2A). The remaining *Myod1*

populations we named myoblast clusters 1 to 5 (M1-M5), and the last one C1 for committed 1

Dominici et al.,

(Figure 2A). The freshly isolated MuSCs of day 0 (d0) segregated into Q1 and Q2 (Figure 2-figure supplements 1D, Supplementary File 3), which in addition to *Pax7* and *Myf5*, expressed markers of MuSC quiescence (*Fos, Egr1, Jun*), and early activation markers (*Myod1, Mt1, Mt2,* Supplementary File 1). Our Q1 and Q2 populations are similar to quiescence and early activation populations reported recently from freshly isolated (De Micheli *et al*, 2020; Dell'Orso *et al*, 2019; van Velthoven *et al*, 2017). The two *Myog* expressing clusters expressed other markers of early differentiation (*Acta2*; DM1), and late differentiation (*Tnnt3, Myl1, Acta1*; DM2) (Supplementary File 1). An enrichment for cell cycle and proliferation markers was found throughout the remaining 5 undifferentiated myoblast clusters (*Cdk1*, *Ccnd1*, *Mki67*, *Top2a,* *Birc5,* and *Cenpa*; M1-M5) (Supplementary File 1).

The control DMSO day 4 (d4) sample was distributed among 3 subpopulations of myoblasts (M1, M2, and M4), while two additional days in culture day 6 (d6) contained M1, M2, and M4, but also had differentiated clusters DM1 and DM2 (Figure 2C, 2D; Figure 2-figure supplements 1E, Supplementary File 3). In comparison, day 4 with MS023 (d4MS023) was distributed uniquely among clusters M3 and M5. Day 6 MS023 removed at day 4 (d6MS023rd4) had clusters of day 4 MS023 treatment, as well as DM1 and DM2 (Figure 2C, 2D, Figure 2-figure supplements 2A, 2B, Supplementary File 3). Notably, d6MS023rd4 had nearly twice as many cells in DM1 (20.8%) as d6 (11.5%) (Figure 2D), indicating that the differentiation block induced by MS023 was reversible. In addition, all samples had in common a small subpopulation of cells (<200 cells) in cluster C1 (Supplementary File 3).

Analysis of the top 100 enriched genes in each cluster revealed distinct transcriptional profiles (Supplementary File 1). For example, the d4MS023-occupied cluster M5 was enriched for cell cycle markers (*Cdk1*, *Cdk4*, *Ccnd3*) and other markers of proliferation (*Mki67*, *Birc5*,

Top2a) (Supplementary File 1). The other d4MS023-occupied cluster M3 retained some markers of proliferation (*Ccnd1*), however also expressed the cell cycle inhibitor *Cdkn2a* and the structural muscle gene *Myl6*, in addition to a strong enrichment for ribosomal genes (over 20% of the top 100 markers belonged to the ribosomal protein family, a feature that is unique to cluster M3). Therefore, clusters M3 and M5 are unique to MS023-treated MuSCs and represent proliferation clusters with extensive ribosomal protein expression.

The top 100 enriched genes in each sample were also investigated (Supplementary File 2, Heatmap in Figure 2-figure supplements 3). Interestingly, d4MS023 genes were strongly enriched for the Reactome Pathway of respiratory electron transport, the citric acid cycle, and formation of ATP. In contrast, d4 was enriched for the Reactome Pathways of RNA metabolism, translation, and mRNA splicing (Figure 2-figure supplements 2C, 2D).

The d4 cluster M2 shared many of the same gene enrichments as cluster M5 (*Cdk1*, *Mki67*, *Birc5*, *Top2a)* (Supplementary File 1). Conversely, the other d4 cluster M4 down-regulated these genes while maintaining expression of replication-dependent transcripts such as *Ube2c* and *Dut*, indicating increased heterogeneity in cycling cells compared to d4MS023 (Supplementary File 1). The final d4 cluster M1 resembled the transitional d4MS023 cluster M3 in that it expressed a mix of cell cycle (*Ccnd1*) and differentiation (*Myl6*) markers, however lacked the enrichment of ribosomal genes observed in M3 (Supplementary File 1).

It was important to note is the stark difference in the pathway enrichment signatures of the transitional clusters M1 (d4) and M3 (d4MS023). The genes which were uniquely enriched in cluster M3 were strongly associated with protein synthesis (e.g., *Rps9, Eef1g, Uba52*) (Supplementary File 1, Figure 2-figure supplements 2C, 2D). In contrast, the enriched genes

Dominici et al.,

unique to cluster M1 were associated with cellular response to toxic substance and cellular detoxification (*Anxa1, Txn1, Hmox1, Prdx5*) (Figure 2-figure supplements 2C, 2D).

We further investigated the distribution of expression levels for *Pax7, Myf5, Myod1,* and *Myog* across clusters and samples (Figure 2-figure supplements 2A, 2B). We observed a unique expression pattern for *Pax7* in d4MS023 and d6MS023rd4 samples (Figure 2-figure supplements 2B). In d4 MuSCs, cells were divided into two populations, *Pax7* negative (expression level 0) and *Pax7* positive (standard distribution around expression level 1). In d6 myoblasts, *Pax7* positive cells maintain the same level of *Pax7* expression, but a higher proportion of cells became *Pax7* negative, consistent with canonical *Pax7* expression during MuSC differentiation (Yin *et al*, 2013). Meanwhile, with MS023 treatment, three subpopulations emerged, a *Pax7* negative (expression level 0) and two *Pax7* positive cell (standard distribution around expression level 1) populations. The *Pax7* positive cell populations in d4MS023 and d4MS023rd4 had higher *Pax7* expression levels than their untreated counterparts and were more comparable with day 0 (quiescent) MuSC *Pax7* expression levels (Figure 2-figure supplements 2B).

Trajectory analysis reveals temporally distinct expression patterns in MuSCs treated with MS023 with an enrichment for energy metabolism genes

Using the Monocle v2.16.0 R package (Trapnell *et al*, 2014), we conducted trajectory analysis on 3 groups of samples to obtain hierarchical links between clusters: (1) all samples; (2) d0, d4, d6; (3) d0, d4MS023, d6MS023rd4. Monocle analysis placed each cell from the 9 clusters (Q1/Q2, M1-5, and DM1/2) onto a pseudotime axis based on differential gene expression patterns. The trajectory analysis of all samples pooled produced a pseudotime axis with a single branchpoint

Dominici et al.,

and 3 cell states which we labelled Q for quiescence, M for myoblast, and DM for differentiating myoblast (Figure 3A). Cells from the Q1 and Q2 clusters were found at the beginning of pseudotime, cells from the M1-5 clusters populated the area around the branchpoint, and cells from DM1/2 mainly populated the upward-oriented branch, following an overall trajectory of Q1/2→M1-5→DM1/2 (Figure 3-figure supplements 1A).

Day 0 cells populated the beginning of pseudotime, with d4 and d4MS023 cells appearing shortly after. d6 and d6MS023rd4 cells had a similar distribution as d4 and d4MS023, with the exception of having increased density around the terminus of the upward-oriented branch (Figure 3-figure supplements 1A). Interestingly, d4MS023 and d6MS023rd4 cells emerge later along the pseudotime axis than d4 and d6 cells and appeared closer to the branchpoint (Figure 3-figure supplements 1A).

We examined the genes which were significantly differentially regulated across the branchpoint of the pooled sample trajectory to confirm whether this split is representative of the molecular events which determine whether MuSCs will commit to differentiation or continue to proliferate. As expected, genes involved in the myogenic process were highly upregulated along the branch that diverges upwards along the trajectory (eg. *Tnnt1, Tnnt2, Acta1, Myog*), while genes involved in cell cycle and proliferation were upregulated along the branch that diverges downwards along the trajectory (eg. *Mki67, Cdca8, Top2a, Birc5*) (Figure 3-figure supplements 1B, 1C).

Trajectory analysis was also performed on a subset of samples (d0→d4→d6; DMSO trajectory and d0→d4MS023→d4MS023rd4; MS023 trajectory) to identify treatment-specific alterations in the molecular events which drive fate-determining decisions (Figure 3B, 3C, 3E,

Dominici et al.,

3F). Both the DMSO and MS023 trajectories retained a single branch point indicating that the

overall lineage patterns were conserved.

Closer inspection of genes which were significantly differentially regulated across the

branchpoint in the DMSO and MS023 trajectories revealed a unique signature in the MS023-

trajectory. The list of genes which changed significantly across the branchpoint for both

trajectories (7094 for the DMSO trajectory, 7616 for the MS023 trajectory) were filtered for

genes which were unique to each condition. The DMSO trajectory had 1517 unique genes, while

the MS023 trajectory had 2037 unique genes (Figure 3-figure supplements 1D). Interestingly, the

MS023 trajectory-unique genes revealed an enrichment for oxidative phosphorylation and

mitochondrial ATP synthesis (Figure 3F, 3G), consistent with cluster marker analysis for

MS023-specific clusters ((Figure 2-figure supplements 2C, 2D): *electron transport, ATP*

synthesis). Expression of select genes involved in the mitochondrial electron transport chain

(*Ndua2, Ndufa4, Uqcr10, Cox4I1, Cox5b, Cox8a, Atp5c1, AtpIf1, Atp5j2*) were further examined

for expression level within the scRNAseq UMAP plot, and it was confirmed that they were

elevated in MS023-specific clusters (Figure 4A). Moreover, RT-qPCR analysis of a subset of

these genes confirmed they were upregulated in d4MS023 MuSCs compared to d4 MuSCs

(Figure 4-figure supplements 1A). Therefore, these pathways both define the identity of MS023-

treated MuSCs, and these pathways may serve a role in fate determination.

The transition of MuSC from quiescence to proliferation is accompanied by a sharp

reduction in oxidative metabolism and a shift towards glycolysis (L'Honore *et al.*, 2018; Ryall *et*

al., 2015). Therefore, the retention of a transcriptional signature indicating high levels of

mitochondrial oxidative phosphorylation in MS023-treated cells was unexpected. We sought to

validate these findings in *ex vivo* cultured MuSCs by performing metabolic analysis with

Dominici et al.,

Seahorse Extracellular Flux Analyzer. We isolated MuSCs from C57BL/6 mice and seeded them onto matrigel-coated 96-well plates treated with 1μM MS023 or DMSO for 48 h (n= 3 mice per treatment condition). Oxygen consumption rate (OCR) was first measured to characterize mitochondrial bioenergetics (Figure 4B). As predicted, MS023-treated MuSCs displayed increased OCR measurements at nearly all timepoints (Figure 4B, p= 0.000001 - 0.02), with significantly elevated basal respiration (p= 0.006) and maximal respiration (p= 0.04), and a trend of increased ATP production (approaching statistical significance, p=0.1). To confirm an increase in mitochondrial biogenesis, d4 and d4MS034 MuSCs were stained with MitoTracker CMXRos (ThermoFisher Scientific). The average intensity of the MitoTracker signal was significantly increased in d4MS023 cells (Figure 4C, 4D, p< 0.0001)

We next determined whether markers of glycolysis were also differentially regulated in MS023-treated MuSCs. Indeed, several of the marker genes for MS023-specific clusters were components of glycolysis which displayed increased expression compared to clusters of DMSO-treated cells (*Hk1, Eno1, Pfkm, Gapdh, Pkm, Slc2a1*; Figure 4-figure supplements 1B). We next performed extracellular acidification rate (ECAR) analysis as an indicator of glycolysis again using the Seahorse Extracellular Flux Analyzer. MS023-treated cells were strikingly more glycolytic than DMSO-treated cells (Figure 4-figure supplements 1C). Glycolysis, glycolytic capacity, and glycolytic reserve were all significantly increased (p= 0.02, p= 0.004 and p= 0.001, respectively) (Figure 4-figure supplements 1C). As further indicators of glycolysis, the growth media supernatant of d4 and d4MS023 cultured cells was analyzed using a Nova Biomedical Bioprofile 400 analyzer. As expected, d4MS023 cells had significantly higher levels of glucose uptake (measured as grams/liter per 10,000 cells, p= 0.004). Additionally, the glycolytic byproduct lactate was present in higher concentrations d4MS023 media and was undetectable in

Dominici et al.,

the d4 media (Figure 4-figure supplements 1D). Collectively, these findings indicate that MS023-treated MuSCs utilize both OxPhos and glycolysis at elevated levels compared to untreated control cells to boost cellular metabolism, suggesting a possible mechanism through which enhanced proliferation is supported.

In vitro expanded MS023-treated MuSCs retain the potential to become mature myoblasts

We next wanted to validate that removal of MS023 created conditions which are permissive to terminal differentiation. Primary MuSCs were cultured under four conditions before switching to differentiation media: (1) for four days with DMSO, (2) washout for additional two days without DMSO (DMSOwo), (3) for four days with MS023, and (4) washout for additional two days without MS023 (MS023wo). Cells treated for four days were switched to differentiation media with the continued presence of DMSO or MS023. Washout cells were switched to differentiation media without DMSO or MS023. Expectedly, cells differentiated in the presence of MS023 had an impaired ability to form multinucleated myotubes and had a poor fusion index of 19% compared to the 77% fusion index observed with DMSO treated MuSCs (Figure 5A, 5B). Interestingly, MS023wo cells had completely restored their ability to terminate differentiation, with their fusion index of 76% being comparable to that of DMSOwo cells (78%) (Figure 5C, 5D). Together, these experiments define MS023 as a reversible inhibitor of type I PRMT activity which enhances MuSC proliferation and self-renewal while still allowing for full differentiation capabilities upon removal of the compound.

Type I PRMT inhibitor MS023 enhances MuSC engraftment

Dominici et al.,

We next sought to confirm that MS023 washout conditions create a pool of MuSCs that are regeneration-competent upon engraftment into an injured muscle *in vivo*. Primary green fluorescent protein (GFP) expressing MuSCs were purified from a β-actin-GFP reporter mouse (C57BL/6-Tg(CAG-EGFP)10sb/J) using an FACSAriaIII cell sorter (Figure 5-figure supplements 1B, 1C), and treated with MS023 or DMSO *in vitro* for 6 days to allow for their expansion. Following culturing, 15,000 GFP$^+$ myoblasts from each group were injected into the tibialis anterior (TA) muscle of wild type mice. One day after stem cell injection, the TA was injured with cardiotoxin (CTX). After 3 weeks, the mice were sacrificed and GFP$^+$ differentiated muscle fibers were quantified following cross-sectional staining of the injured TA muscle (n=3 mice per condition) (Figure 5-figure supplements 1A). Interestingly, the mice that received MS023-treated MuSCs had more GFP$^+$ mature muscle fibers than the mice that received DMSO-treated MuSCs (88 fibers/section ± 32 for MS023 versus 31 fibers/section ± 14 for DMSO, *p*= 0.02) (Figure 5E, 5F). These data indicate that MS023-treated MuSCs were able to differentiate *in vivo* following type I PRMT withdrawal and contribute efficiently to muscle regeneration following injury.

We next wanted to determine whether MS023-treated engrafted cells were able to repopulate the niche. Therefore, we repeated the engraftment experiment with MS023 and DMSO-treated GFP$^+$ MuSCs, and this time re-isolated MuSCs 3 weeks after CTX injection. Strikingly, MS023-treated MuSC engraftment yielded an ~7-fold increase in the number of GFP$^+$ following muscle regeneration (*p*=0.004) (Figure 5G, 5H).

Dominici et al.,

MS023 injection increases muscle strength in *mdx* mice

Patients with DMD lack functional dystrophin, a structural protein required to connect mature

myofibers to the extracellular matrix. The resulting muscle tissue is vulnerable to injury and is

caught in constant cycles of muscle degeneration and regeneration (Serrano *et al*, 2011). The

Dmd^mdx^ (mdx) mice harbor a spontaneous mutation in the *dystrophin* gene and are therefore

commonly used as a model for DMD (Bulfield *et al*, 1984; Ryder-Cook *et al*, 1988).

To determine whether MS023 could provide any therapeutic benefits in a dystrophic

context, we delivered 80 mg/kg of MS023 or vehicle via intraperitoneal injection to *mdx* mice

once a day for 3 days. Tail pieces were collected 48 h after the final injection and whole tissue

lysate was analyzed for ADMA- and SDMA-containing proteins using immunoblotting. We

observed reduced ADMA proteins and a subsequent increase in SDMA proteins in MS023-

treated *mdx* mice compared to vehicle-treated *mdx* mice (Figure 6-figure supplements 1A). The

average ADMA relative expression was 0.95 for vehicle treated mice and 0.83 for MS023 treated

mice (p < 0.00041). The average SDMA relative expression was 0.92 for vehicle treated mice

and 0.94 for MS023 treated mice ($p < 0.17$). These whole-body measurements as measured by

tail biopsies show MS023 promotes the decrease of proteins with ADMA and a slight increase in

proteins with SDMA. It is known that inhibition of type I PRMTs or PRMT1 deletion diminishes

ADMA and increases SDMA due to substrate scavenging (Dhar et al, 2013). At 10 days

following the final injection, 2-paw and 4-paw grip strength measurements were taken.

Additionally, endurance was tested by placing mice on a wire grid and inverting them so that the

amount of time spent hanging could be recorded (see Figure 6A for schematic). We observed a

50% increase in 2-paw grip strength ($p= 0.0113$) and a 45% increase ($p= 0.0089$) in 4-paw grip

Dominici et al.,

strength in the MS023-treated mice versus those that received vehicle at the 10-day time point

(Figure 6B). The hanging test to measure endurance showed a positive trend towards increased

endurance at the 10-day time point in MS023 versus vehicle-treated mice, however this was not

statistically significant (p= 0.1) (Figure 6-figure supplements 1B). A final measurement was

performed at the 32-day endpoint, during which mice were placed under terminal anesthesia and

the extensor digitorum longus (EDL) hindlimb muscle was isolated, incubated *ex vivo*, and used

to generate a force/frequency curve. Interestingly, this experiment revealed that MS023-treated

mice responded with a ~30% increase in force compared to their vehicle-treated counterparts (p=

0.00727) (Figure 6C). Moreover, we observed a reduction in the variation of the minimum Feret

diameter measurements of fibers from TA cross sections of MS023-treated mice (p= 0.04)

(Figure 6D, 6E). These findings show that injection of type I PRMT inhibitor MS023 in *mdx*

mice improved muscle strength.

Dominici et al.,

Discussion

In the present manuscript, we show that inhibition of type I PRMTs promoted the *in vitro* proliferation of Pax7$^+$ MuSCs, as visualized by ki67 staining. scRNAseq analysis of MS023 treated MuSCs identified new transitional clusters. MS023-specific subpopulations harboured unique transcriptional signatures of stemness and energy metabolism. The MS023 treated MuSCs exhibited elevation of both glycolysis and OxPhos. Engrafted MuSCs treated with MS023 were efficient at regenerating injured muscle and at repopulating the niche. Treatment of the *mdx* mouse model of DMD with MS023 resulted in enhanced grip strength and force generation. Repression of type I PRMTs altered the metabolic state of cultured MuSCs while maintaining their capacity for self-renewal and to effectively participate in muscle regeneration. These findings suggest that type I PRMT inhibitors may have therapeutic potential for treating certain skeletal muscle diseases.

The ability to tailor energy metabolism to the specific demands of cell proliferation and differentiation is known as metabolic plasticity, and is required for maintaining tissue homeostasis (Folmes *et al*, 2012). The transition from quiescence to proliferation is regulated by a shift from OxPhos to glycolysis (Pala *et al*, 2018; Ryall *et al.*, 2015). During MuSC quiescence, high levels of NAD+ are generated by oxidative metabolism which in turn activates Sirtuin 1 (SIRT1) to deacetylate and repress expression of differentiation genes required for the myogenic program (Ryall *et al.*, 2015). The shift from OxPhos to glycolysis upon exit from quiescence results in reduced NAD+ levels and subsequent activation of differentiation genes. Furthermore, it has been shown that entry to the process of terminal differentiation is mediated by the activation of pyruvate dehydrogenase (PDH), marking a switch from glycolysis to OxPhos (Hori *et al*, 2019). Another key player in metabolic plasticity in MuSCs is AMP kinase, a major

Dominici et al.,

energy sensor in the cell, regulating energy balance and metabolic state (Hardie *et al*, 2016; Herzig & Shaw, 2018). Null alleles of AMPK have contributed to the understanding of its role in MuSCs (Fu *et al*, 2015b; Theret *et al*, 2017). Activated AMPK stimulates autophagy, mitophagy, and mitochondrial biogenesis, thus maintaining mitochondrial homeostasis (Herzig & Shaw, 2018). Our data showed that inhibition of type I PRMTs in MuSCs stimulated the expression of autophagic markers (*Atg5, Lamp1, Lamp2, Sqstm1*) downstream targets of AMPK, however it remains to be determined whether AMPK is involved in MS023-treated cells.

PRMT1 has been shown to interact with AMPK in skeletal muscle during the early stages of muscle atrophy (Stouth *et al*, 2018). Moreover, CARM1 directly methylates AMPK to regulate its activity during muscle response to denervation (Stouth *et al.*, 2020). PRMT1 has also been shown to play a signaling role to regulate thermogenesis. PRMT1 acts through the transcriptional co-activator PGC-1α in human and mouse adipocytes to regulate thermogenic fat activation, and PRMT1-deficient mice were unable to induce the thermogenic program following cold exposure (Qiao *et al*, 2019). Methylation of PGC-1α by PRMT1 was also shown to stimulate mitochondrial biogenesis and may regulate nuclear-encoded mitochondrial genes (Teyssier *et al*, 2005). Additionally, PRMT1-mediated methylation positively regulates the insulin receptor (IR)-phosphatidylinositol 3-kinase (PI3-K) pathway which is required for glucose transport in skeletal muscle (Iwasaki & Yada, 2007). Overexpression of PRMT1 in the liver under hypoxic conditions causes hypermethylation of FoxO1 and increased translocation to the nucleus, resulting in reduced glucose uptake (Bayen *et al*, 2018). Therefore, these findings indicate that PRMT1 methylates key regulators of cellular metabolism and highlight a crosstalk between metabolic effectors and type I PRMTs.

Dominici et al.,

Treatment of MuSCs with MS023 resulted in metabolic reprogramming of MuSCs, supporting a role for type I PRMTs as metabolic regulators. *In vitro*, MS023 has been shown to inhibit several type I PRMTs at nanomolar (nM) concentrations (Eram et al., 2016). It is well-documented that PRMT1 is the major cellular type I enzyme (Pawlak et al, 2000) and this is why PRMT1, but not the other type I PRMTs are embryonic lethal in mice (Guccione & Richard, 2019). The numerous published data *in cellulo* with MS023 are thus far only reproduced by PRMT1-deficiency by siRNA or knockout, suggesting that MS023 actions *in vivo* are predominantly mediated by inhibiting PRMT1 (Gao et al, 2019; Plotnikov et al, 2020; Wu et al, 2022; Zhu et al, 2019). In addition, PRMT1 is by far the most expressed type I PRMT in MuSCs at every time point tested in skeletal muscle post-cardiotoxin injury (uninjured, and 0.5, 2, 3.5, 5, 10, 21 days post-injury) by single cell RNAseq (Oprescu *et al.*, 2020). Thus, the effects of MS023 on MuSCs are most likely mediated by inhibition of PRMT1.

scRNAseq analysis of MS023-treated MuSCs identified new transitional clusters which harboured transcriptional signatures of stemness and energy metabolism. DMSO clusters M1/M2/M4 and MS023 clusters M3/M5 were both enriched for proliferation markers (*Cdk1, Mki67*), and M3/M5 also uniquely harboured elevated metabolic genes including components of the electron transport chain (*Atp5k, Cox5a, Ndufa2*) and components of glycolysis (*Eno1, Gapdh*). The simultaneous elevation of both glycolytic and OxPhos components in MS023 subpopulations likely contributes to the enhanced proliferation phenotype. MuSC subpopulations have been characterized at the single-cell level during muscle regeneration, revealing regulatory mechanisms that guide the transition from quiescence to activation, proliferation, and differentiation. A general progressive elevation of metabolic enzyme expression has been noted from low levels in MuSCs isolated from uninjured muscle, to slightly elevated levels in MuSCs

Dominici et al.,

isolated from acutely injured muscle (60 h after injury), to the highest levels in cultured

proliferating MuSCs (Dell'Orso *et al.*, 2019). A more in-depth analysis of MuSC subpopulations

throughout muscle regeneration investigated additional time points after injury (2, 5, and 7 days)

and generated a hierarchical continuum model of MuSCs throughout the regeneration process,

with a focus on ligand-receptor cell communication networks (De Micheli *et al.*, 2020).

Additionally, analysis of young and aged MuSCs revealed that, while they have similar

transcriptional signatures, aged MuSCs display delayed activation state dynamics when exiting

quiescence, thus preventing them from entering the differentiation program as efficiently as

young MuSCs (Kimmel *et al*, 2020). It has been previously reported that the quiescent MuSCs

captured by scRNAseq exist in two groups, one 'quiescent' and one 'early activation', wherein the

early activation group highly expresses *Fos* and *Jun* while down-regulating *Hox* genes (van den

Brink *et al*, 2017). Our Q1 and Q2 clusters are in alignment with these two states (Q1 -

quiescence; Q2 - early activation), and bare transcriptional similarities to our MS023-specific

clusters M3 and M5, such as upregulated *Fos* and *Jun*, as well as high levels of *Pax7*. Notably,

capture of rare transient MuSC states remains difficult due to poor sampling or limited cell

number. To overcome these issues, one study evaluated 365,000 single cells/nuclei from over

100 combined datasets, allowing for the characterization of short-lived MuSC subpopulations

that emerge throughout the myogenic process (McKellar *et al*, 2021). We show that MS023

treatment generates subpopulations of self-renewing MuSCs that have not been previously

identified, suggesting that transient cell states may be also amplified through treatment with

epigenetic inhibitors, thus facilitating a more in-depth understanding of their function and

contributions to muscle regeneration.

Dominici et al.,

PRMTs are known as epigenetic regulators by methylating histones directly and by serving as coactivators/repressors (Xu & Richard, 2021). We now show MuSC cells treated with type I PRMT inhibitors have altered metabolism favouring proliferation and self-renewal, however, the mechanism whether epigenetic, regulating of mRNA splicing or a signaling cascade remains to be defined. It has been shown that inhibition of the epigenetic modulator *Setd7* enhances the proliferation of cultured MuSCs, while retaining their stemness by preventing transport of β-catenin into the nucleus, thereby failing to activate the differentiation program (Judson *et al.*, 2018). Taken together, these findings suggest that inhibiting methyltransferases can affect MuSC fate and perhaps both lysine (Setd7) and arginine (MS023) inhibitors might provide a more favorable combination to promote the expansion of MuSCs, while maintaining their stem cell-like properties.

We report heightened engraftment capabilities of MS023-treated MuSCs accompanied by high Pax7 expression levels. It has been shown that freshly isolated MuSCs retain high Pax7 expression levels and are superior at engrafting compared to cultured MuSCs (Montarras *et al.*, 2005; Sacco *et al.*, 2008). Generating stable Pax7 expression in myogenic precursor cells with lentiviral delivery of transgenes is a strategy for enhancing engraftment potential following *ex vivo* expansion of MuSCs (Kim *et al*, 2021), although this approach may be hampered by safety concerns. Therefore, we have identified an additional strategy for increasing Pax7 expression and improving engraftment efficiency and self-renewal of *ex vivo* expanded MuSCs through inhibition of type I PRMTs. Furthermore, our findings show that injection of MS023 in the dystrophic mouse *mdx* model led to enhanced muscle strength with effects lasting up to 30 days. We cannot exclude if the effect of MS023 was mediated by an expansion of the MuSC pool or by an effect on other cell types, such as a direct impact on the myofibers. The goal of this

Dominici et al.,

experiment was to provide a therapeutic perspective for the possible use of type I PRMT

inhibitor for the treatment of DMD. Our findings suggest that type I PRMT inhibitors may have

therapeutic potential for treating certain skeletal muscle diseases. For instance, to improve the

efficacy of autologous cell therapy, the dystrophin-deficient MuSCs collected from DMD patient

and corrected by CRISPR prime editing (Happi Mbakam *et al*, 2022) could be treated with

MS023 to maintain their stemness and enhance their cell engraftment capacity.

    In sum, our findings show that inhibition of type I PRMTs increased the proliferation

capabilities of MuSCs with altered cellular metabolism, while maintaining their stem-like

properties such as self-renewal and engraftment potential.

Dominici et al.,

Materials and Methods

Mice

C57BL/6J (Jackson Laboratory 000664) were the wild type mice used for MuSC FACS

purification for scRNAseq, muscle fiber isolation, and for all other *in vitro* experiments.

β-Actin GFP mice (C57BL/6-Tg(CAG-EGFP)10sb/J, Jackson Laboratory 003291) were used to

obtain GFP$^+$ MuSCs for further implantation experiments. Mice lacking dystrophin expression

(C57BL/10ScSn-*Dmd^{mdx}*/J, Jackson Laboratory 001801) were used for intraperitoneal MS023

injection and muscle physiology assessment. The experiments with the *Dmd^{mdx}* mice were

performed at Sainte-Justine and were approved by the CHU Sainte-Justine Research Ethics

Committee and performed in compliance with the Comité Institutionnel des Bonnes Pratiques

Animales en Recherche (CIBPAR; approval number 2020-2668) in accordance with the

Canadian Council on Animal Care guidelines. All other mouse husbandry and experiments were

conducted in accordance with the Institutional Animal Care and Use Committee (IACUC) of

McGill University. All animal procedures conducted at McGill were approved by the Animal

Welfare Committee of McGill University (protocol #3506).

Primary MuSC isolation

Skeletal muscle tissue was isolated from the abdominal and diaphragm muscles of wild type

mice and muscle stem cells were isolated as previously described using fluorescence activated

cell sorting (FACS) (Pasut *et al*, 2012). Briefly, dissected muscles were minced with dissection

scissors and digested with collagenase/dispase solution (2.4U/ml collagenase D, 2.4U/ml

Dispase II in Ham's F10 media) at 37°C for 1h. Digested tissue was triturated and filtered

through a 40 μM cell strainer. Cells were pelleted for 18 min at 1800 rpm and resuspended in 2%

Dominici et al.,

BSA/PBS. Cells were stained for 15 min at room temperature with ITGA7-Alexa647 (R&D systems) for positive selection, and PE-CD45 (Invitrogen), PE-CD11b (Invitrogen, PE-CD31 (BD Pharmigen), and PE-ScaI (BD Pharmigen) for negative selection. Hoescht was used to gate the living cells. Cells were washed once with 2% BSA/PBS and pelleted prior to final resuspension and one last filter through a 40 μM cell strainer. ITGA7+/CD45-/CDCD11b-/Sca1-/Hoechst+ cells were sorted into full myoblast growth media using the FACSAriaIII cell sorter (BD Biosciences).

Myoblast growth and differentiation culture

Purified MuSCs were seeded onto collagen-coated plates and expanded in growth media (Ham's F10 media with 20% FBS, 2.5 ng/mL human recombinant bFGF, and 1% Penicillin/Streptomycin) at 37°C and 5% CO_2. Media was replenished every two days. To differentiate myoblasts into myotubes, myoblasts were grown to 90% confluency in growth media, washed twice with 1X PBS, and switched to differentiation media (DMEM, 1% FBS, and 1% Penicillin/Streptomycin). For inhibitor treatment, cells were incubated with 0.033% DMSO or 1 μM MS023 (Sigma) in 0.033% DMSO and media was replenished every second day for the duration of the indicated treatment time.

Western blot

Proteins from total cell or tissue lysate (50 mM HEPES [pH 7.4], 150 mM NaCl, and 1% Triton X-100) were resolved on SDS 8-15% polyacrylamide gels and transferred onto nitrocellulose membranes using the Trans-Blot turbo transfer system (BioRad). Membranes were blotted with

Dominici et al.,

the primary antibodies against ADMA (Epicypher, SKU: 13-0011), SDMA (Millipore Cat# 07-413, RRID:AB_310595), and β-Actin (Sigma-Aldrich Cat# A2228, RRID:AB_476697) overnight at 4°C. Following 3 washes in TBST, membranes were incubated with HRP-conjugated secondary antibodies (Sigma) for 45 min and visualised on X-ray films with Western Lightning Plus ECL (Perkin Elmer).

Cultured myoblast immunofluorescence

Myoblasts expanded in growth media were seeded onto collagen-coated glass coverslips (VWR) in 6-well plates. Coverslips were transferred to a 12-well plate containing 4% paraformaldehyde (PFA) and cells were fixed for 15 min at room temperature. Cells were then permeabilized with 0.2% Triton X-100, 0.125M glycine in PBS for 12 min at room temperature (RT). Incubation with blocking buffer (2% BSA, 5% horse serum and 0.1% Triton X-100) proceeded for 1 h at RT. Primary antibodies were diluted in blocking buffer to detect Pax7 (Developmental Studies Hybridoma Bank, 1:100), MyoD (Santa Cruz Biotechnology, 1:200), or ki67 (abcam, 1:1000). After 16h incubation at 4°C, cells were washed 3 times with 1X PBS for 10 min. Secondary antibody (AlexaFluor anti-mouse or anti-rabbit 488nm or 568nm) was used at a dilution of 1:400 in blocking buffer for 45 min in the dark at RT. Cells were washed 3 times for 10 min with 1X PBS. Finally, the cover slips were transferred to a microscope slide and mounted with ProLong Gold Antifade Mountant with DAPI (ThermoFisher Scientific). For MitoTracker staining, primary MuSCs were seeded onto 8-well Lumox chamber slides (Sarstedt) and cultured for the indicated time points. Cells were then incubated for 30 min with a final concentration of 100 nM MitoTracker Red CMXRos (ThermoFisher Scientific) at 37°C and 5% CO_2. Cells were fixed with ice-cold 100% methanol at -20°C for 15 min and washed 3 times for 10 min with 1X PBS

Dominici et al.,

prior to mounting with ProLong Gold Antifade Mountant with DAPI. All cells were visualized

on a Zeiss Axio Imager M1 microscope (Carl Zeiss, Thornwood NY), and resulting images were

analyzed using Zeiss' ZEN Digital imaging suite software.

Muscle fiber isolation and culture

Wild type mice were sacrificed and their extensor digitorum longus (EDL) muscles were

dissected using standard dissection techniques. Isolated muscles were incubated with 0.4%

collagenase (Sigma) in DMEM for 30 min at 37°C and 5% CO_2. Whole muscle was then

triturated with a plastic disposable Bohr pipette to dissociate individual fibers from the whole

muscle as described previously(Gallot *et al*, 2016). To mimic activating conditions, fibers were

cultured in fiber growth media (DMEM plus 20% FBS, 1% chick embryo extract, 2.5 ng/mL

bFGF, 1% penicillin/streptomycin) at 37°C and 5% CO_2. For quiescent satellite cell analysis,

fibers were fixed immediately following dissociation using 4% PFA prepared fresh in 1X PBS.

Muscle fiber immunofluorescence

Cultured muscle fibers from wild type mice were fixed in 4% paraformaldehyde PFA and

washed twice with 1X PBS. Fibers were then permeabilized with 0.2% Triton X-100, 0.125M

glycine in PBS for 15 min at RT. Blocking followed for 1 h at room temperature with 2% BSA,

5% horse serum and 0.1% Triton X-100. Primary antibodies were diluted in blocking buffer to

detect Pax7 (Developmental Studies Hybridoma Bank, 1:100), MyoD (Santa Cruz

Biotechnology, 1:200), ki67 (Abcam, 1:1000). After 16 h incubation at 4°C, fibers were washed

3 times with 1X PBS for 10 min. Secondary antibody (AlexaFluor anti-mouse or anti-rabbit

488nm or 568nm) was used at a dilution of of 1:400 in blocking buffer for 45 min in the dark at

Dominici et al.,

RT. Fibers were washed 3 times for 10 min with 1X PBS. Finally, the fibers were transferred to a microscope slide outlined using an ImmEdge hydrophic barrier pen and mounted with ProLong Gold Antifade Mountant with DAPI (ThermoFisher Scientific). Fiber-associated satellite cells were then visualized on a Zeiss Axio Imager M1 microscope (Carl Zeiss, Thornwood NY), and resulting images were analyzed using Zeiss' ZEN Digital imaging suite software.

scRNAseq sample preparation and computational analysis

Each biological replicate for the scRNAseq corresponded to one C57BL/6 mouse. The purified MuSCs were cultured in Ham's F10 (Gibco) with 20% FBS (HyClone), 2.5 ng/mL human recombinant bFGF (Gibco), 1% Penicillin/Streptomycin (Wisent Inc.) with 0.033% DMSO or 1 µM MS023 in 0.033% DMSO. The medium was changed on day 2 and day 4 of culturing. The purified MuSCs from each replicate were stained for viability with calcein-AM and ethidium-homodimer1 (P/ N L3224 Thermo Fisher Scientific). scRNA libraries were generated using the GemCode Single- Cell Instrument (10x Genomics, Pleasanton, CA, USA) and Single Cell 3' Library & Gel Bead Kit v2 and ChIP Kit (P/N 120236 P/N 120237 10x Genomics). The sequencing ready libraries were purified with SPRIselect, quality controlled for sized distribution and yield (LabChip GX Perkin Elmer), and quantified using qPCR (KAPA Biosystems Library Quantification Kit for Illumina platforms P/N KK4824) as previously described (Couturier *et al*, 2020). Libraries were subsequently shipped and sequenced using Illumina NovaSeq6000 at IGM Genomics Center, UCSD, San Diego, CA. Cell barcodes and UMI (unique molecular identifiers) barcodes were demultiplexed and paired-end reads were first aligned to the mouse genome (mm10) using the Cell Ranger software v3.1.0 (10X Genomics, https://support.10xgenomics.com/single-cell-gene-expression/software/pipelines/latest/what-is-

Dominici et al.,

cell-ranger). Pre-processing was then carried out with the Seurat v3.2.0 R package (Butler et al.,

2018). Genes detected in less than 3 cells as well as cells containing less than 200 genes detected

were removed. Cells were further filtered out for each sample based on the distribution of genes

detected as well as the percentage of mitochondrial counts to balance the number of cells per

sample to ~4000, and the raw count matrices of all samples were merged. Read counts for each

cell were then normalized by the cell total, multiplied by 10000 and natural-log transformed. The

expression of the 2000 genes with highest cell-to-cell variation was standardized and the

heterogeneity associated with mitochondrial contamination was regressed out. Principal

component analysis was performed on the scaled data and the top 10 principal components were

used to construct a K-nearest neighbor cell graph. Clustering of cells was carried out through the

Louvain algorithm with the granularity parameter set to 0.4 and visualized with the Uniform

Manifold Approximation and Projection (UMAP) (Becht et al., 2019) dimensional reduction

technique using the Scanpy v1.5.2 python module (Wolf et al., 2018). Cluster biomarkers were

identified using the Wilcoxon Rank Sum test. Cell trajectories across pseudotime were analyzed

by the Monocle v2.16.0 R package (Trapnell et al., 2014). Cell progress was defined by

differentially expressed genes based on the clusters identified by Seurat. The dimensionality of

the data was reduced through the Discriminative Dimensionality Reduction with Trees

(DDRTree) algorithm to two dimensions and the cells were ordered along the trajectory

according to pseudotime. Genes with branch-dependent expression were identified through the

branched expression analysis modeling (BEAM) test. RNA velocity analysis was performed by

the scVelo v0.2.2 python module (Bergen et al., 2020). Spliced and unspliced mRNAs were first

distinguished through the velocyto v0.17.17 python module (La Manno et al., 2018). Velocities

Dominici et al.,

representing the direction and speed of cell motion were then computed and projected onto the
UMAP embedding.

Oxygen consumption rate and extracellular acidification measurements

Oxygen consumption rates (OCR) and extracellular acidification rate (ECAR) were measured
using a Seahorse XFe96 Flux Analyzer and analyzed with Wave 2.6.0 software (Agilent
Technologies). FACS sorted muscle stem cells were seeded in a matrigel-coated 96-well plate
and cultured with MS023 or DMSO for 48 h. Cells were incubated in MitoStress test assay
media (DMEM 5030 media, 10mM glucose, 1mM sodium pyruvate, 2mM glutamine, PH7.4) or
GlycoStress test assay media (DMEM 5030 media, 2mM glutamine, pH 7.4) 1 h prior to OCR
and ECAR measurements, respectively. Oligomycin (3mM, Sigma-Aldrich), carbonyl cyanide-p-
trifluoromethoxy-phenylhydrazone (FCCP; 1mM, Abcam) and rotenone-antimycin A (RAA;
2.5mM, Sigma-Aldrich) were added to cells to measure OCR parameters while glucose (10mM,
Sigma-Aldrich), Oligomycin (1mM, Sigma-Aldrich) and 2-DG (100mM) were used to measure
ECAR parameters. Following the assay, cells were stained with crystal violet and nuclei were
counted in each well for normalization.

MuSC engraftment and muscle histology

Primary MuSCs were FACS-purified from donor GFP mice and cultured with MS023 or DMSO
for 5 days. Cells were then trypsinized, resuspended in 1X PBS, and pelleted for 10 min at 1,800
RPM. Cell pellets were resuspended in 1ml of 1X PBS and counted using a haemocytometer.
15,000 cells from each condition were then injected into the TA muscle of wild type mice.
Recipient mice were also injected with 50 μl of 10 μM cardiotoxin (CTX) 24 h prior to MuSC

Dominici et al.,

engraftment to induce muscle regeneration. Recipient mice were sacrificed 3 weeks after CTX injection, and the TA muscles were dissected and fixed in 2% PFA at 4°C for 16 h. Fixed TA muscles were then embedded in OCT and frozen prior to cryosectioning onto a glass microscope slide. Resulting tissue sections were permeabilized for 12 min with 0.2% Triton X-100, 0.125M glycine in PBS at RT. Blocking followed with M.O.M blocking reagent (Vector Laboratories) for 1 h at RT. Primary antibodies were diluted in blocking reagent to detect Pax7 (Developmental Studies Hybridoma Bank, 1:10) and laminin (Sigma, 1:50). After 16h incubation at 4°C, sections were washed 3 times with 1X PBS for 10 min. Secondary antibody (AlexaFluor anti-mouse or anti-rabbit 488nm or 568nm) was used at a dilution of 1:400 in blocking reagent for 45 min in the dark at RT. Sections were then washed 3 times for 10 min with 1X PBS. Tissue sections were mounted with ProLong Gold Antifade Mountant with DAPI (ThermoFisher Scientific) and covered with a coverslip. Visualization was performed on a Zeiss Axio Imager M1 microscope (Carl Zeiss, Thornwood NY), and resulting images were analyzed using Zeiss' ZEN Digital imaging suite software.

MS023 injection in mdx mice

12-week-old *mdx* mice received an intraperitoneal injection of 80 mg/kg MS023 (Sigma) dissolved in 50 μl N-methyl-2-pyrrolidone, 200 μl Captisol, 200 μl polyethylene glycol 400 and 550 μl PBS once per day for three consecutive days. As control, 12-week-old mice received vehicle (50 μl N-methyl-2-pyrrolidone, 200 μl Captisol, 200 μl polyethylene glycol 400 in 550 μl PBS) alone. Tail pieces were collected 48h after the last injection and lysed for western blot analysis with anti-ADMA and anti-SDMA and β-actin antibodies. Grip strength and hanging test

measurements were taken at 10 days after the final injection. 29 days after the final injection, mice were anesthetized and sacrificed for endpoint *ex vivo* force measurements.

Grip strength measurements and hanging test

Grip strength was measured for the front two paws and for all four limbs using a Bioseb Grip Strength Test instrument. Each mouse was placed on the rod (2 paws) or mesh (4 paws) and pulled from the tail three times with 1 min rest between trials. The highest measurement was retained for subsequent analysis. To assess endurance, mice were placed on a plastic mesh taped to a hollow cylinder. The cylinder was slowly inverted over soft bedding to allow mice to grip the mesh, and the amount of time each mouse remined suspended before falling onto the bedding was recorded 3 times with 2 min rest between trials. The longest time measurement was retained for analysis.

Ex vivo force measurements of mdx mice

Mice were anesthetized with pentobarbital sodium (50 mg/kg). Proximal and distal tendons of the EDL were attached with silk suture (3.0) and the muscle was carefully isolated and placed in a buffered physiological solution (Krebs-Ringer supplemented with glucose and bubbling carbogen gas) maintained at 25°C (Dort *et al*, 2021). The distal tendon of the EDL muscle was attached to the electrode, and the proximal tendon was attached to the force lever arm (300C-LR dual-mode lever; Aurora Scientific, Canada). Muscle length was adjusted to find the optimal muscle length (L_0) at which it generates the maximum isometric twitch tension. The EDL muscle was allowed to equilibrate in the contractile bath for 10 min equilibration prior the contractile measurement. Muscle was stimulated at different frequencies (10, 25, 50, 80, 100, 150 Hz), with

Dominici et al.,

2 min rest between each stimulation, to obtain a force-frequency curve. Thereafter, muscle length

and weight were measured. Specific muscle force (N/cm^2) was determined using the following

formula: (force (N) x fiber length (0.44 x L_0 for the EDL muscle) x muscle density (1.06

g/cm^3))/muscle mass (g).

Figure Legends

Figure 1. Enhanced self-renewal of MS023-treated MuSCs.

(A) Muscle fibers cultured for 48 h with MS023 or DMSO. Pax7 identifies MuSCs, and ki67 identifies proliferating cells. Scale bar represents 50 μM. (B) Quantification of total MuSCs per fiber. 30 fibers were counted per condition, horizontal bar represents average number of MuSCs per fiber (n=3 mice per condition). (C) Muscle fibers cultured for 48 h with MS023 or DMSO. 30 fibers counted per condition (n=3 mice per condition). Scale bar represents 50 μM. (D) Quantification of Pax7/MyoD expressing MuSCs from (C). (E) Pax7/MyoD immunofluorescence staining of cultured myoblasts treated with MS023 or DMSO for 48 h. Scale bar represents 50 μM. (F) Quantification of Pax7/MyoD expressing cells from (E).

Figure 2. Single-cell graph-based clustering analysis.

(A) UMAP embedding representation for all cells. (B) Gene expression density on the UMAP embedding plot of myogenic markers Pax7, Myf5, MyoD, and Myogenin. (C) Distribution of cells from each sample within the UMAP embedding representation. (D) Proportion of cells from each sample belonging to each of the 10 identified clusters.

Figure 3. Pseudotime trajectory of pooled DMSO- and MS023-treated MuSCs.

(A) Trajectory of all cells depicting three cell states. Pseudotime starts at the left endpoint of the plot. Q: Quiescence. M: Proliferating myoblast. DM: Differentiating myoblast. (B-D) Monocle trajectory of day-0 and DMSO-treated samples (B), heatmap of top differentially regulated genes across pseudotime (C) and GO enrichment analyses of DMSO-unique branchpoint genes (D). (E-G) Monocle trajectory of day-0 and MS023-treated samples (E), heatmap of top differentially

Dominici et al.,

regulated genes across pseudotime (F) and GO enrichment analyses of MS023-unique branchpoint genes (G).

Figure 4. MS023-treated proliferating MuSCs display elevated oxidative phosphorylation.

(A) UMAP plots showing expression of components of the electron transport chain localized to MS023 clusters. (B) Seahorse XF96 analysis of oxygen consumption rate (OCR) in DMSO and MS023-treated freshly isolated primary MuSCs and quantification of basal respiration, maximal respiration, and ATP-linked production. Error bars represent mean ± SEM from 7 individual wells per condition. (C) MitoTracker staining (red) of freshly isolated MuSCs treated with DMSO (upper panel) or MS023 (lower panel) and counterstained with DAPI to visualize nuclei. Minimum 100 cells quantified per condition from 3 independent experiments. Scale bar represents 20 µM. (D) Quantification of MitoTracker signal intensity of cells from (C), error bars represent mean ± SEM from 3 individual replicates, > 100 nuclei quantified per condition ($p < 0.0001$).

Figure 5. MS023 treatment is reversible and allows expanded MuSCs to differentiate *ex vivo* and *in vivo*.

(A) Immunofluorescence of MyHC counterstained with DAPI in primary myotubes that were differentiated in the presence of DMSO or MS023 following 4 days of treatment with DMSO or MS023. (B) Fusion index calculated as the ratio of nuclei within multinucleated myotubes to total nuclei from >200 nuclei per condition, error bars represent mean ± SEM from 3 individual replicates. (C) Immunofluorescence of MyHC counterstained with DAPI in primary myotubes that were differentiated in the absence of DMSO or MS023 following 4 days of treatment with

Dominici et al.,

DMSO or MS023 and 2 days of washout. Scale bar represents 50 μM (D) Fusion index

calculated the same as 6B. (E) Immunofluorescence of GFP⁺ myofibers following transplantation

of 15,000 DMSO or MS023-treated MuSCs. Scale bar represents 50 μM. (F) Quantification of

GFP⁺ myofibers. Error bars represent mean ± SEM from 3 individual biological replicates. (G)

Representative FACS plots of re-isolated MuSCs following engraftment and muscle

regeneration. P3 represents the population of purified GFP⁺ MuSCs. (H) Fold enrichment of

MS023-treated MuSC re-isolation compared to DMSO. Error bars represent mean ± SEM from 3

individual biological replicates.

Figure 6. *In vivo* **administration of MS023 to dystrophic mice improves muscle strength.**

(A) Experimental schema. (B) Normalized grip strength measurements taken from two forelimbs

and all 4 limbs of mice treated with vehicle or MS023 10 days after the last injection. Error bars

represent mean ± SEM from 6 biological replicates. (C) Force/frequency curve generated for

mice treated with vehicle or MS023. (D) Representative cross-sectional area of TA muscles

isolated from mice treated with vehicle or MS023 and immunostained with anti-laminin

antibodies to visualize myofibers. Scale bar represents 50 μM. (E) Quantification of the variance

coefficient of TA muscle minimum fiber Feret measurement from mice treated with vehicle or

MS023. Error bars represent mean ± SEM from 3 biological replicates, >200 fibers measured per

mouse)

Dominici et al.,

Figure 1-figure supplements 1

Type I PRMT inhibitor MS023 increases proliferation of MuSCs most by inhibition of PRMT1.

(A) Primary MuSCs were isolated from WT mice and seeded on collagen-coated 6 well plates. Upon seeding, cells were treated with 1μM MS023, 1 μM TP064, or DMSO for 6 days. Cells were trypsinized and counted at days 2, 4 and 6 using a haemocytometer.

(B) We investigated their expression from publicly available single cell RNAseq dataset (Oprescu *et al.*, 2020), which performed analysis on skeletal muscle at different time points post-cardiotoxin injury (uninjured, and 0.5, 2, 3.5, 5, 10, 21 days post-injury).

(C) Western blot of total asymmetric dimethyl arginine (ADMA) from whole cell lysate of primary myoblasts treated with MS023 (1μM) or DMSO.

(D) Ki67 immunofluorescence of MS023-treated primary myoblasts. Error bars represent mean ± SEM from 3 individual experiments, minimum of 200 cells per condition counted. Scale bar represents 50 μM.

(E) Ki67-PE immunostained MS023-treated primary myoblasts analyzed with FACS, foldchange of mean intensity calculated compared to DMSO-treated cells. Error bars represent mean ± SEM from 3 individual replicates.

(F) (left) Immunofluorescence of 14th passage MuSCs with DMSO or MS023 treatment, Pax7 (green), MyoD (purple), counterstained with DAPI. Scale bar represents 50 μM. (right) Pie chart representing quantification of Pax7 and MyoD expression from cells in left panel.

Figure 2-figure supplements 1

scRNAseq analysis of DMSO- and MS023-treated MuSCs.

Dominici et al.,

(A) Reproducibility of average gene expression across biological replicates represented as Pearson correlation coefficients.

(B) UMAP plot labelled with clusters 0-9.

(C) Distribution of individual samples mapped onto the UMAP embedding representation for all cells.

(D) Distribution of cells from d0 across the clusters represented in a pie chart. Cluster colour legend indicated on the right.

(E) Distribution of individual clusters mapped onto the UMAP embedding representation for all cells.

Figure 2-figure supplements 2

scRNAseq analysis of DMSO- and MS023-treated MuSCs.

(A) Expression RidgePlots of key myogenic markers Pax7, Myf5, MyoD (Myod1) and Myog separated by cluster.

(B) Expression RidgePlots of key myogenic markers Pax7, Myf5, MyoD (Myod1) and Myog separated by sample.

(C) GO enrichment terms of top 100 marker genes unique to cluster M1 (DMSO specific, top panel), M3 (MS023 specific, middle panel), and genes that are common between clusters M1 (DMSO) and M3 (MS023) (lower panel).

(D) GO enrichment terms of top 100 marker genes unique to d4 cells (top panel) and d4MS023 cells (lower panel).

Figure 2-figure supplements 3

scRNAseq analysis of DMSO- and MS023-treated MuSCs.

Heatmap of the top 100 enriched genes in each cluster.

Figure 3-figure supplements 1

Monocle trajectory analysis of DMSO- and MS023-treated MuSCs.

(A) Cell trajectories for each sample and cluster, with the pseudotime starting at the left endpoint of the plot.

(B) Heatmap of significantly differentially expressed genes across the branchpoint of the pooled sample trajectory.

(C) Distributions in the kinetic trends of each lineage for the expression for selected genes.

(D) Venn diagram of overlapping differentially regulated genes across the branchpoint of the DMSO and MS023 trajectories with a *q* value <0.1.

Figure 4-figure supplements 1

Glycolysis is increased MS023-treated MuSCs.

(A) Fold change of selected OxPhos genes in response to treatment with MS023. Bulk RNA was isolated from freshly purified primary myoblasts. Error bars represent mean ± SEM from 3 biological replicates.

(B) UMAP plots showing expression of components of glycolysis localized to MS023 clusters.

(C) Seahorse XF96 analysis of extracellular acidification rate (ECAR) in DMSO and MS023-treated freshly isolated primary MuSCs and quantification of glycolysis, glycolytic capacity, and glycolytic reserve. Error bars represent mean ± SEM from 7 individual wells per condition.

Dominici et al.,

(D) Measurement of glucose uptake (left) and lactate production (right) as quantified from the media of d4 (DMSO) and d4MS023 (MS023) MuSCs. Error bars represent mean ± SEM from 3 independent experiments.

Figure 5-figure supplements 1

Type I PRMT inhibitor MS023 enhances MuSC engraftment

(A) Experimental outline for MuSC engraftment.

(B) FACS plot of primary purified MuSCs represented as P4 (0.6% of the total population).

(C) The purity of sorted cells is 99%.

Figure 6-figure supplements 1

MS023 decreases ADMA containing proteins globally and increases strength in *mdx* mice.

(A) Whole tissue lysate from homogenized tail pieces of mice treated with Vehicle or MS023 probed with antibodies against total asymmetric dimethyl arginine (ADMA), symmetric dimethyl arginine (SDMA), and actin for loading control. The ADMA levels normalized to β–actin from left to right are: (0.94, 0.95, 1.03, 0.99, 0.91, 0.89), (0.86, 0.83, 0.83, 0.85, 0.78, 0.82). The SDMA levels normalized to β-actin from left to right are: (0.95, 0.89, 0.94, 0.90, 0.94, 0.91), (0.93, 0.95, 0.96, 0.93, 0.93, 0.94).

(B) Hanging test measurements taken from *mdx* mice treated with vehicle or MS023 at 10d post-injection. Error bars represent mean ± SEM from 6 biological replicates.

Supplementary file 1. Expressed genes per cluster. Quiescence 1 and 2 (Q1 and Q2), myoblast clusters 1 to 5 (M1-M5), and differentiated myoblasts 1 and 2 (DM1 and DM2) clusters.

Dominici et al.,

Supplementary file 2. Top 100 genes enriched per cluster of MuSCs purified from 8-week-old

C57BL/6 mice immediately after 1) isolation (termed d0; sample day 0), and 2) culture in growth

medium for 4 days with 0.033% DMSO as control (sample d4) or with 1μM MS023 (sample

d4MS023), and 3) grown in growth media for 6 days with 0.033% DMSO removed at day 4

(sample d6), or 6 days in culture with 1μM MS023 removed at day 4 (sample d6MS023rd4)**.**

Supplementary file 3. Sample distribution across clusters. The number of cells and the

percentage distributed within clusters Q1, Q2, C1, M1, M2, M3, M4, M5, DM1 and DM2 is

indicated.

Dominici et al.,
