1 Abstract

2 Plastics pose an increasing and significant threat to both human and environmental health.
3 While many fungi can degrade a variety of organic polymers, investigations into which fungi
4 possess the potential to remediate environmental plastics contamination have only recently
5 become a priority. To help address this need, we tested the null hypothesis that chronic plastics
6 contamination has no impact on the fungal communities across a plastics/no plastics transition in
7 a beach sand in northern Oregon. We used sieving and binocular microscopy of microplastics
8 (particle size, $12.6\mu\text{m} \pm 5.5\mu\text{m}$, detection range 1-5000 μm) to confirm the plastics/no plastics
9 transition. We used paired plot design to collect samples across this transition and analyzed the
10 fungal communities using high-throughput DNA sequencing methods for fungal ITS-2. Results
11 indicated that the beach sand contaminated with plastics held an extensive fungal community,
12 while un-contaminated sand held no fungal community at all. System dominants included
13 *Acremonium* and *Penicillium*, both free-living ascomycete fungi that have shown plastics-
14 degrading capabilities in lab studies, and the ectomycorrhizal genus, *Russula* a symbiotic fungus
15 that has known plastics-degrading enzyme capabilities. Also amongst dominant genera was a
16 human fungal pathogen (genus *Malassezia*) that causes chronic skin disease. These results
17 provide new fungal models for further studies of fungal and ectomycorrhizal remediation of
18 plastics contaminated contaminated beach sand.
19

1 Introduction

2 Plastics and microplastics represent a persistent and growing global environmental health
3 problem (Reviewed by 1) Hence, managing this problem is of paramount importance. To date,
4 landfilling remains the most often used method of disposal and though methods such as
5 incineration and recycling are both expensive and environmentally hazardous, and hence lack the
6 scale to provide a sufficient solution. In light of this, focus has been shifting to the use of
7 microbes, including fungi, as vehicles for plastics degradation and elimination.

8 Fungi are widespread and resilient, inhabiting both terrestrial and aquatic habitats, and
9 function as the Earth's recyclers able to break down some of the most recalcitrant polymers,
10 including plastics (1). Research is showing that some fungi may possess the capability in the lab,
11 not all fungi are adapted to conditions necessary to perform the functions in nature or under
12 conditions created by industrial processes (e.g. 2). Thus, using metagenomic methods to identify
13 fungi in the "plastisphere" that could be effective either as free-living degraders in plastics-
14 polluted areas and/or as sources of enzymes for use in engineered recycling methods is of
15 paramount importance (1). In this study we performed a preliminary survey of the fungal
16 communities across a plastics/no plastics transition in a beach sand habitat in Oregon in order to
17 ascertain impacts of plastics contamination on fungal communities in this habitat. The overall
18 goal of our work is to not only study impacts of plastics contamination on beach sands, but also
19 to locate fungal candidates for use in plastics degradation and remediation.

20 Methods

21 **Collections:** Samples were taken at a beach in Oregon (45.722568, -123.941561) across a
22 transition of sand containing no plastics to sand chronically contaminated by plastics. To
23 confirm the state of contamination in the two habitat types, three samples from each of three

1 plots in each sand type were collected into sterile 50ML Falcon tubes and sent to EMSL
2 Analytical, Inc in Cinnaminson NJ for analysis by sieve separation and stereoscopic
3 microscopic analysis, particle size range 1 μ m - 5000 μ m diameter.

4 **Molecular Methods:** Three samples from each of three plots on each side of the transition
5 were collected into sterile 50ML Falcon tubes and sent to Novogene Corp for analysis. The
6 fungal microbiomes of the three beach sand types were determined via Internal Transcribed
7 Spacer (ITS-2) amplicon sequencing (itags) using fungal-specific primers (ITS3F;
8 [GCATCGATGAAGAACGCAGC-ITS4R](#); [TCCTCCGCTTATTGATATGC](#)). PCR reactions
9 were undertaken using sand extractions using the PHusion High-Fidelity PCR Master Mix (New
10 England Biolabs). Libraries were generated using the TruSeq DNA PCR-Free Prep Kit
11 (Illumina) and quality was assessed using Qubit 2.0 on a Thermo Scientific Fluorometer and
12 Agilent Bioanalyzer 2100 system. The library was sequenced using an IlluminHiSeq2500
13 platform. ITS-2 itags were generated by Novogene Corporation. Sequences were assembled
14 using FLASH V1.2.7 (3) and data were quality filtered using QIIME V2 using the default
15 parameters (4). Chimeras were removed using UCHIME (5). Sequences were analyzed using
16 UPARSE v7.0.1001 (6) and sequences with >97% similarity were clustered as OTUs. Multiple
17 sequence alignments were performed using MUSCLE V3.8.31 (7). Taxonomic annotation was
18 accomplished using the GreenGene Database version 13_8 (included in the QIIME software
19 package mentioned above), based on the RDP Classifier v2.2, and also by using QIIME-
20 compatible SILVA (8) and BLAST (9). Results indicated that there were no fungi in the beach
21 sand without plastics no alpha and beta diversity statistics were performed. Good's Coverage
22 was used to estimate the percent of total species represented in the sampling.

23

Results

1 Results of plastics measurements confirmed the transition between contaminated and
2 uncontaminated beach sands (See Table). High throughput DNA sequencing resulted in 80,000-
3 200,000 unique tags, and with >99.9% Good's Coverage. Analysis indicated that no fungi were
4 present in the beach sand without plastics, thus no alpha or beta diversity analyses could be
5 performed on this dataset. In contrast, the plastic-contaminated beach sand had a fungal
6 community comprised of both free-living and ostensibly plant-associated fungi, dominated by
7 only a few taxa (Figure). Of particular interest are *Acremonium*, *Penicillium*, *Malassezia* and
8 *Russula*.

9 Discussion

10
11 We have indications of at least two free-living fungi that show promise for plastics
12 degradation in beach sands, namely *Acremonium* and *Penicillium*. *Acremonium* is known to
13 degrade petrochemical contaminants in the lab (e.g., 10). The species of *Acremonium* present
14 here, *A tubakii* is a marine fungus that is known to produce high levels of laccase, an enzyme that
15 is known to degrade plastics (e.g., 11). Similarly, our data support earlier indications that
16 *Penicillium* (e.g., 12) could be a good candidate for plastics breakdown in a wide range of
17 habitats. Both fungi will therefore be put forward for future study by our lab as both free-living
18 solutions to plastics contamination and as enzyme sources. *Malassezia* is a yeast-like pathogenic
19 fungus that causes peritonitis, blood infections and an assortment of chronic and recurrent skin
20 diseases (e.g., 13, 14). While this fungus may be utility as an enzyme source, the human health
21 implications most likely preclude its use in field settings and this result has interesting
22 implications for the impacts of marine plastics on human health.

23 Interestingly two ectomycorrhizal fungi *Russula* and *Inocybe*, were found in the Top 10 most
24 abundant fungi in plastics-contaminated beach sand. Ectomycorrhizal fungi are endosymbionts

1 of most flowering plants and conifers and provide these plant hosts with the nitrogen necessary
2 for survival (15). Some ectomycorrhizal fungi appear to be capable of enzymatic breakdown of
3 at least small polymers in soils as a replacement for host plant carbon in times of need (16, 17).
4 These results imply that some ectomycorrhizal fungi might also be attracted to microplastics as a
5 nutrient source. The anatomy and physiology of *Russula* in particular suggests that species in
6 this genus could prove useful in addressing plastics contamination, particularly when used in
7 combination with host plants. These fungi form a contact exploration type of hyphal network
8 that is known to interact closely with nutrient substrates and to produce enzymes that could be
9 useful in plastics degradation (18). When used in combination with host plants they could be
10 used not only for plastics remediation, but also in combined plastics degradation-reforestation
11 efforts.

12 To summarize, this preliminary survey provides models for at least two free-living fungi
13 (*Acremonium* and *Penicillium*) that could be useful in plastics remediation efforts and at least
14 one ectomycorrhizal fungal genus (*Russula*) that could be used in combination with native plants
15 for phytoremediation strategies. In addition, a severe human pathogen was apparently attracted
16 to the conditions created by plastics in beach sand, a finding that has interesting health
17 implications for beach goers. This survey was only preliminary and we plan a broader survey
18 across plastics no-plastics transitions in beach habitats at this site comparing sand with and
19 without native pines and willows to further our pool of potential fungal remediation agents.
