41 **Abstract**:

42 Mucosal associated invariant T (MAIT) cells recognize conserved microbial metabolites
43 from riboflavin synthesis. Striking evolutionary conservation and pulmonary abundance
44 implicate them in antibacterial host defense, yet their roles in protection against clinically
45 significant pathogens are unknown. Murine *Legionella* infection induced MR1-dependent
46 MAIT cell activation and rapid pulmonary accumulation of MAIT cells associated with
47 immune protection detectable in fully immunocompetent host animals. MAIT cell
48 protection was more evident in mice lacking CD4+ cells, whilst profoundly
49 immunodeficient RAG2$^{-/-}\gamma$C$^{-/-}$ mice were substantially rescued from uniformly lethal
50 *Legionella* infection by adoptively-transferred MAIT cells. This protection was
51 dependent on MR1, IFN-γ and GM-CSF, but not IL-17, TNF-α or perforin. Protection
52 was enhanced and observed earlier post-infection in mice that were Ag-primed to boost
53 MAIT cells before infection. Our findings define a significant role for MAIT cells in
54 protection against a major human pathogen and indicate a potential role for vaccination to
55 enhance MAIT cell immunity.

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

60 Mucosal-associated invariant T (MAIT) cells are innate-like lymphocytes with the
61 potential to recognize a broad range of microbial pathogens. MAIT cells express a 'semi-
62 invariant' αβ T cell receptor (TCR) and recognize small molecules presented by the
63 major histocompatibility complex (MHC) class I-related molecule (MR1)[1,2]. These
64 molecules comprise derivatives of the riboflavin biosynthetic pathway[3-5], which is
65 conserved between a wide variety of bacteria, mycobacteria and yeasts[3,6], but is absent
66 from mammals, and therefore provides an elegant mechanism to discriminate host and
67 pathogen. Indeed the enzymatic pathway required for riboflavin synthesis has been
68 identified in all microbes shown to activate MAIT cells, and is absent in those that do
69 not[3].

70

71 A striking feature of MAIT cell immunity is the high level of conservation of MR1 across
72 150 million years of mammalian evolution[7-9], implying a strong evolutionary pressure to
73 maintain the MAIT cell compartment. Furthermore, MAIT cells have a strong pro-
74 inflammatory phenotype[10] and are abundant in humans in blood and lung tissue[11], whilst
75 in C57BL/6 mice are found in greater abundance in the lungs than any other organs[12].
76 Together these features implicate MAIT cells in a critical role in respiratory host defense.
77 However, very few pathogens have been demonstrated *in vivo* to cause activation and
78 proliferation of MAIT cells[13,14]. In studies implicating a role for MAIT cells in protective
79 immunity against pathogens, the definition of these cells was limited by the lack of MR1-
80 Ag tetramers[14]. To date no studies have clearly defined a functional role for MAIT cells
81 in protection against a clinically important human pathogen.

82

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

83 Using a model of bacterial lung infection with the intracellular bacteria *Salmonella*
84 *enterica* serovar Typhimurium we have previously shown that riboflavin gene-competent
85 bacteria can cause rapid activation and proliferation of MAIT cells[13]. We therefore
86 hypothesized that this response could also be elicited with an authentic human lung
87 pathogen and would contribute to protection against disease.

88 *Legionella spp* are facultative intracellular pathogens, gram-negative, flagellated bacteria
89 which, when inhaled, cause a spectrum of disease from self-limiting Pontiac fever to
90 severe, necrotic pneumonia: Legionnaire's disease[15]. Incidence of Legionnaire's has
91 nearly trebled since 2000, with >5000 cases/year in the USA, inflicting a 10% mortality
92 despite best treatment[16]. In North America and Europe[16] the predominant pathogen is *L.*
93 *pneumophila* whilst in Australasia and Thailand over 50% of cases are caused by *L.*
94 *longbeachae*[17].

95 Here we have used MR1 tetramers loaded with the potent MAIT cell ligand 5-(2-
96 oxopropylideneamino)-6-D-ribitylaminouracil (5-OP-RU)[18] to specifically identify[4] and
97 characterize MAIT cells in human *in vitro* and murine *in vivo* models of lung infection
98 with the two most clinically significant *Legionella* species: *L. pneumophila* and *L.*
99 *longbeachae*. Our data reveal that MAIT cells contribute to protection against fatal
100 infection with *Legionella*, by a mechanism that is dependent on MR1 and interferon
101 (IFN)-γ / granulocyte macrophage-colony stimulating factor (GM-CSF). Protection is
102 partial in immunocompetent hosts but becomes increasingly evident as other arms of
103 immunity are disabled such as in CD4 T cell-deficient animals. Protection ultimately
104 becomes "all or nothing" in profoundly immunodeficient mice $RAG2^{-/-}\gamma C^{-/-}$ mice. These

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

105 studies dissect the mechanisms by which MAIT cells contribute to protection against an
106 important human disease and a model intracellular pathogen.

107 ## Results

108 ### Human MAIT cells are activated by *Legionella* infection *in vitro* via MR1

109 We[3,13] have previously shown that MAIT cells are activated by microbial species that
110 express the riboflavin biosynthetic pathway; a finding which has been confirmed by
111 others[6]. We therefore investigated whether *Legionella* species known to cause serious
112 pulmonary infections in humans – *L. pneumophila*[15,19] and *L. longbeachae*[17] – and to
113 express the necessary *rib* enzymes[20], could activate human MAIT cells. First, bacterial
114 lysates of *L. pneumophila* and *L. longbeachae* stimulated a reporter cell line expressing a
115 MAIT TCR (Jurkat.MAIT-A-F7)[3] in the presence of an MR1-expressing lymphoid cell
116 line (C1R.MR1)(Figure 1A). Stimulation was dose-dependent, and could be specifically
117 blocked by anti-MR1 antibody[21]. Next we used a well-characterized human monocytic
118 cell line (THP-1)[22] as an antigen presenting cell co-cultured with flow-sorted human
119 peripheral blood CD3+Vα7.2+CD161+ cells. We observed activation of MAIT cells
120 when co-cultured with THP1 cells infected for 27 hours with live *L. longbeachae* (Figure
121 1B,C). Intracellular infection of wild type THP1 and THP-1:MR1+ cell lines induced
122 expression of TNF-α by human MR1-5-OP-RU tetramer+ MAIT cells. Activation was
123 related to the infective dose, and was specific to MAIT cells and not non-MAIT CD3+ T
124 cells. Activation was MR1-dependent, as it did not occur in the presence of cells in which
125 we had disrupted the MR1 gene using a CRISPR/Cas9 lentiviral system (THP1:MR1-).
126 MAIT cells also expressed IFN-γ in the presence of MR1-over-expressing cells

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

127 (THP1:MR1+), but expression was minimal using the parental cell line (THP1), which
128 has very low constitutive surface expression of MR1.

129 To visualize MAIT cells *in situ* we infected healthy human lung tissue *ex vivo* with *L.*
130 *longbeachae* and observed CD3+TCRVα7.2+IL-18Rα+ MAIT cells within the lung
131 parenchyma in the proximity of *Legionella* bacilli 24 hours post-infection using
132 immunofluorescence microscopy (Figure 1D).

133 These findings indicate that *Legionella* induces potent MAIT cell immune responses *in*
134 *vitro* suggesting that MAIT cells are likely to play a role in protection against *Legionella*
135 pneumonia.

136

137 **MAIT accumulate in the lungs during *Legionella* infection *in vivo***

138 Next we examined the impact of *Legionella* infection on MAIT cells *in vivo* in a murine
139 model using intranasal infection with live *L. longbeachae.* TCRβ+ MR1-5-OP-RU
140 tetramer+ cells were visible in the lung parenchyma using immunofluorescence
141 microscopy within three days post-infection (Figure 2A). There was striking enrichment
142 of pulmonary MAIT cells (from here on defined as CD45+TCRβ+ MR1-5-OP-RU
143 tetramer+ cells), which comprised up to 30% of all pulmonary αβ-T cells after 7 days
144 (Figure 2B, C). MAIT cell accumulation was dependent on size of initial inoculum and
145 was proportionately much larger for MAIT cells – 580-fold absolute increase at 10^5
146 colony-forming units (CFU) (P<0.0001) – than conventional αβ-T cells (maximum 9.4-
147 fold, P<0.0001) (Figure 2C,D). Accumulation occurred rapidly over 7 days post infection
148 (DPI), with absolute numbers peaking at day 10 (Figure 2E). Furthermore, despite a

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

149 subsequent 20-fold contraction from peak frequencies (P=0.005), overall expansion of the
150 MAIT cell population was long-lived, persisting >280 DPI (Figure 2E,F). Interestingly,
151 although MAIT cells have been implicated in recruitment of non MAIT T cells [14], we did
152 not observe any significant difference in pulmonary recruitment of αβ-T cells in MR1-/-
153 mice, which have an absolute deficiency of MAIT cells[12,13]. Likewise, i.n. infection with
154 $2x10^7$ CFU *L. pneumophila* similarly induced a rapid expansion of MAIT cells
155 (Supplementary Figure S1), although more modest than *L. longbeachae.* As C57BL/6
156 mice are susceptible to *L. longbeachae*[17], *L. longbeachae* was selected as the most
157 appropriate model for more detailed investigation.
158

159 Histology of lungs from mice infected with $2x10^4$ CFU of *L. longbeachae* at 7DPI
160 demonstrated pronounced alveolar infiltration of neutrophils and macrophages,
161 leukocytoclasia, aggregates of fibrin and accumulation of edema fluid and epithelial
162 shedding, consistent with the typical features of human *L. pneumophila*
163 pneumonia[15](Supplementary Figure S2A,B). Blinded analysis of these sections using a
164 qualitative histological score at multiple time-points post infection revealed inflammation
165 peaked at day 7, but there were no gross histological differences in the severity of
166 pneumonia between C57BL/6 and MR1-/- mice (Supplementary Figure S2C). To
167 determine the cellular localization of *L. longbeachae* we measured bacterial burden in
168 flow-sorted cells from collagenase-dispersed murine lungs 3 days post infection. Most
169 viable bacilli localized within neutrophils, but evidence of infection of macrophages and
170 dendritic cells was also observed (Supplementary Figure S2D).
171

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

172 To explore MAIT cell function we investigated the dynamics of their cytokine profile
173 throughout infection. During acute *L. longbeachae* infection MAIT cells secreted
174 interleukin (IL)-17A, IFN-γ, GM-CSF (Figure 3A, Supplementary Figure S3) and TNF-α
175 (data similar to INF-γ, not shown). Expression of IL-17A was abundant throughout the
176 course of the infection, whilst IFN-γ secretion was significantly higher during the acute
177 infection than in naïve cells or after resolution (each $P<0.005$, Figure 3B). Conversely,
178 expression of GM-CSF was lowest during acute infection and peaked after disease
179 resolution ($P=0.0006$ acute v resolution). This correlated with a shift in expression of
180 nuclear transcription factors associated with Th1 or Th17 differentiation. In naïve mice
181 most (81±4%, mean ±SD) MAIT cells expressed the orphan nuclear receptor, retinoic
182 acid–related orphan receptor γt (RORγt) alone: a master regulator of Th17 cell
183 differentiation (Figure 3C, 3D). A minority (13±4%) of cells expressed both RORγt and
184 the Th1 regulator T-bet, and very few expressed T-bet alone. However, during acute
185 infection and long-term post infection there was a marked shift in phenotype towards
186 predominant co-expression of RORγt and T-bet in 64±5% and 69±3% of MAIT cells
187 respectively. MAIT cells expressing T-bet alone were only observed at significant
188 frequencies (14±3%) in acute infection. Thus the consistent secretion of IL-17A in all
189 stages of infection and the transient increase of IFN-γ secretion during acute infection
190 reflect the changes in transcription factor profile we observed, suggesting the formation
191 of an authentic memory pool of MAIT cells and pointing to a specific role for IFN-γ in
192 the acute response to infection.

193

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

194 **MAIT cell protection against life-threatening *Legionella* infection is enhanced and**
195 **accelerated by prior boosting**

196

197 To determine whether MAIT cells contribute to immune protection against *Legionella* we
198 compared bacterial burden in lungs of C57BL/6 and MR1-/- mice throughout infection.
199 Bacterial load increased by 2.5 log over the initial inoculum, peaking at 3 days post-
200 infection (3DPI). In normal C57BL/6 mice we observed a significant difference in
201 bacterial load but not until days 10 and 14 post infection. This was of the order of one log
202 in CFU, consistent with relatively impaired bacterial clearance in MAIT cell deficient,
203 MR1-/- mice (Figure 4A,B).

204

205 In specific pathogen-free C57BL/6 mice baseline frequencies of MAIT cells are very
206 low[12,13], potentially due to lack of natural exposure to diverse environmental pathogens.
207 We have previously shown that MAIT cells can be expanded *in vivo* by intranasal
208 exposure to the MAIT cell ligand 5-OP-RU with a Toll-like receptor (TLR) agonist such
209 as the TLR9 agonist CpG or TLR2 agonist S-[2,3-bis(palmitoyloxy)propyl] cysteine
210 (Pam2Cys) to furnish a MAIT cell costimulus[13]. To understand whether MAIT cell
211 vaccination might impact on protection observed against *Legionella* infection of the lung,
212 we used this approach to specifically expand pulmonary MAIT cells one month prior to
213 *Legionella* infection, without affecting conventional T cell frequencies (Figure 4C,D).
214 Prior exposure to 5-OP-RU and CpG enhanced MAIT cell numbers in the lungs and was
215 associated with protection against infection as reflected in a reduction in bacterial load in

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

216 C57BL/6 versus MR1-/- mice (compare Figures 4A, B to Supplementary Figure S4). This
217 protective effect became apparent earlier than observed in wild type C57BL/6 mice with
218 reduced CFU seen on days 5 and 7 post-infection and comparable on d10 post-infection
219 (compare Figures 4A, B to Supplementary Figure S4), as MAIT cell numbers became
220 indistinguishable in boosted and non-boosted mice (not shown). When a direct
221 comparison was made between MR1-/- mice, C57BL/6 mice and C57BL/6 mice that had
222 been boosted by 5-OP-RU and Pam2Cys, bacterial burden was significantly lower on
223 days 5 ,7 and 10 post-infection in wild-type mice that had received this prior MAIT cell
224 boosting (Figure 4E). This demonstrates the potential to augment MAIT cell-mediated
225 protection by the prior administration of synthetic ligands as a 'vaccine'.

226 These data demonstrate that MAIT cells contribute actively to *Legionella* protection in
227 the context of an intact immune system and that this protection is more rapid and of
228 greater magnitude when mice are first vaccinated to expand MAIT cells before infectious
229 challenge.

230

231 **MAIT cell-mediated protection is more apparent in immune deficient mice**

232 Studies of other intracellular pathogens have demonstrated high levels of functional
233 redundancy in the ability of different lymphocytes subsets to control bacterial growth *in*
234 *vivo*[23]. We hypothesized that by removing partially-redundant effects of other
235 lymphocyte subsets, the protective effects of MAIT cells would become more apparent.
236 CD4+ T cell-derived IFN-γ has been shown to play an essential role in achieving
237 bacterial clearance of *Salmonella* Typhimurium[23]. We therefore used GK1.5 transgenic

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

238 mice, which express the anti-GK1.5 antibody and are CD4+ T cell deficient[24], and
239 compared these with GK1.5.MR1-/- mice which lack both CD4+ cells and MAIT cells.
240 As expected, we observed a protective effect of MAIT cells through reduced bacterial
241 burden apparent even earlier in the course of infection than with wild type mice
242 (statistically significant by day 7 p.i) (Figure 4F).

243

244 To further unmask the potential of MAIT cells in protection, we removed additional
245 layers of immunity by studying the impact of adoptively transferred MAIT cells into
246 profoundly immunodeficient Rag2$^{-/-}$γC$^{-/-}$ mice. We first expanded pulmonary MAIT cells
247 by i.n. inoculation of donor mice with *S.* Typhimurium BRD509, as previously
248 described[13]. Flow-sorted pulmonary MAIT cells from these mice were then adoptively
249 transferred into recipient Rag2$^{-/-}$γC$^{-/-}$ mice in which Rag2 and the common γ chain are
250 deleted, leading to absence of T, B and NK cells. After transfer, administration of anti-
251 CD4 and anti-CD8 mAbs was used to further deplete any residual contaminating
252 conventional T cells (Figure 5A). After adoptive transfer, MAIT cells expanded
253 spontaneously to generate a stable population by two weeks (Figure 5B, Supplementary
254 Figure S5A) which expressed the nuclear transcription factor and master regulator of
255 innate-like T cell development promyelocytic leukemia zinc finger(PLZF) (Figure S5B)
256 [25].

257

258 Strikingly, the presence of adoptively-transferred MAIT cells was sufficient to rescue
259 completely Rag2-/-γC-/- mice from fatal infection with 10^3 CFU *L. longbeachae* (Figure

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

260 5C, X_2 P<0.0001) in the absence of other components of adaptive immunity. Using a
261 higher inoculum (10^4 CFU) we observed this protection was reduced by blockade with
262 anti-MR1 mAb, which was associated with significantly reduced survival (X_2 P=0.005)
263 and with increased bacterial load amongst surviving mice (P=0.0004), consistent with an
264 MR1-dependent mechanism (Figure 5D,E).

265 **MAIT cell-protection is dependent on IFN-γ**

266 To determine the mechanism by which MAIT cells provide this protection we used
267 adoptive transfer of MAIT cells from mice with deficiencies in cytotoxic capability or in
268 pro-inflammatory cytokines. The protective effect of MAIT cells on both survival of
269 $Rag2^{-/-}\gamma C^{-/-}$ mice or on bacterial burden was not impaired in MAIT cells lacking the
270 cytolytic proteins perforin or granzymes A and B, nor in MAIT cells unable to express
271 IL-17A or TNF-α (Figure 6A,B). We observed a small increase in bacterial burden when
272 transferred MAIT cells were deficient in GM-CSF (0.49 log-fold difference in CFU,
273 P=0.026), but this was not associated with significant differences in survival. By contrast
274 protection was critically dependent on MAIT cell derived IFN-γ, with decreased survival
275 (P<0.0001) and a 2.8 log-fold increased bacterial burden (P<0.001) when MAIT cells
276 were deficient in IFN-γ. Furthermore these mice all succumbed to *Legionella* infection by
277 day 37 p.i. .

278 The use of adoptive transfer of *in vivo* expanded MAIT cells provides compelling
279 evidence that MAIT cells can confer protection against important human pathogens and
280 demonstrates this protection depends upon their capacity to produce IFN-γ and to a lesser
281 extent GM-CSF.

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

282

283 ## Discussion

284 Our findings show that MAIT cells are activated and proliferate in response to *Legionella*
285 infection, leading to enhanced immune protection *in vivo* that is dependent on IFN-γ and
286 GM-CSF. This protection is evident earlier and of greater magnitude if mice are first
287 vaccinated to expand and prime MAIT cells which are otherwise present in small
288 numbers in normal mice. Protection by MAIT cells is characterized by more rapid
289 reduction in bacterial loads and is MR1-dependent suggesting mediation via antigen-
290 specific activation. Remarkably, MAIT cell protection against *Legionella* was non-
291 redundant and even evident in fully immune competent mice. The protective effect of
292 MAIT cell immunity became more evident as layers of immunity were removed in host
293 mice, firstly in GK1.5 mice lacking only CD4+ T cells and then in more profoundly
294 immundeficient $Rag^{2-/-}\gamma C^{-/-}$ mice, lacking conventional T cells, B cells and NK cells. This
295 observation is important given that studies of primary immunodeficiencies[26] imply
296 redundancy of different lymphocyte subsets is a typical feature of pathogen immunity
297 especially for innate mechanisms such as NK cells and innate lymphoid cells. Indeed, in
298 the absence of B, T and NK cells MAIT cells were absolutely critical for survival in
299 *Legionella*-infected mice revealing their important potential in compromised hosts. As
300 this mechanism was dependent on MR1, which presents small molecules derived from
301 riboflavin biosynthesis[3-5], this demonstrates *in vivo* the potential for control of *Legionella*
302 by detection of riboflavin metabolites.

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

303 These observations suggest how the contribution of MAIT cells to immune protection
304 may be critical to survival in clinical, naturally-occurring severe infection. The mortality
305 we observe from *Legionella* does not coincide with the time of peak bacterial load – on
306 day 3 post-infection – but later, between days 6 and 14 post-infection, at which point
307 MR1-/- mice had 0.78 to 1.1-log fold higher bacterial load than wild-type mice. In
308 essence, MAIT cells may be the difference between life and death in knife-edge
309 infections where host immunity is partially compromised by comorbidities or
310 predisposing factors, or where patients are exposed to large bacterial doses.

311

312 Although MAIT cells have both cytotoxic activity[27] and the ability to rapidly produce
313 pro-inflammatory cytokines including interleukin IL-17A, TNF-α and IFN-γ[10], the
314 protective effect of MAIT cells against *Legionella* infection was not dependent on TNF-α
315 or IL-17A, but instead relied upon the capacity of MAIT cells to secrete IFN-γ and GM-
316 CSF. This is consistent with a study of *Francisella* infection[28] where GM-CSF reduces
317 bacterial burden late in the course of infection, although this did not translate into a
318 significant survival difference. Nor did the protective effect depend on the key cytotoxic
319 effector molecules: perforin and granzymes A/B. This is in contrast to work suggesting
320 MAIT cell cytotoxicity is important for control of *Shigella*-infected HeLa cell lines *in*
321 *vitro*[27].

322

323 As *Legionella* infects inflammatory cells, particularly neutrophils and macrophages,
324 rather than epithelia, the essential immune function required of MAIT cells in our system

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

325 is likely the IFN-γ-stimulated enhancement of bactericidal activity within these cells in
326 which phagosome function has been subverted. Our findings of IFN-γ production upon
327 MAIT cell activation are consistent with other reports[6,10,14,27], and accord with reports of
328 a role for MAIT cell-derived IFN-γ in limiting growth of *Francisella tularensis* in bone
329 marrow-derived macrophages *in vitro*[14]. IFN-γ has also been shown to enhance
330 bactericidal activity of neutrophils via multiple mechanisms including enhancement of
331 oxidative burst, nitric oxide production, antigen presentation, phagocytosis, and
332 upregulation of CD80/86 co-stimulation and T cell-recruiting cytokines and
333 chemokines[29]. Moreover, given that IFN-γ is critical also for protection against
334 mycobacterial disease including *M. tuberculosis (M.tb)*, it is likely that this early
335 production of MAIT cell-derived IFN-γ may be an important and non-redundant
336 component of protection against mycobacteria. Indeed *in vitro* MAIT cell-derived IFN-γ
337 inhibits growth of *Bacillus Calmette-Guerin* (BCG) in macrophages[30], and the MR1-
338 MAIT cell axis has been linked to susceptibility to BCG in mice[30] and to *M.tb* in
339 humans[31] and mice[32].

340

341 A striking feature of MAIT cell biology is the very low frequencies of MAIT cells we
342 observe in blood or lungs in naïve mice[12,13], in contrast to the marked and long-lived
343 expansion induced by a single infection in our model. Although antigen-naïve MAIT
344 cells have some intrinsic effector capacity[33], the delay between initial microbial exposure
345 and peak MAIT cell frequency may be critical in providing a window of opportunity for a
346 pathogen to exploit[14]. This notion is consistent with our observation that MAIT cell
347 protection can be accelerated by prior expansion of the pulmonary MAIT cell population

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

348 using intranasal synthetic 5-OP-RU and an appropriate TLR agonist. Notably, MAIT cell
349 frequencies are low in early childhood[34], suggesting the potential to enhance the
350 immunogenicity of vaccines given in early life by incorporating such MAIT cell ligands
351 in combination with TLR stimulation, which might for instance promote the recruitment
352 of inflammatory monocyte differentiation via MAIT cell-derived GM-CSF[28]. A
353 protective effect of expanding MAIT cells could contribute to heterologous protection
354 afforded by neonatal BCG vaccination against other, unrelated classes of pathogens[35].
355 Vaccination with MAIT cell ligands might help resolve chronic infections where MAIT
356 cell frequencies may be reduced due to other therapies[11], comorbidities or activation
357 induced cell death[36].

358

359 Our findings define a significant role for MAIT cells in pulmonary host defense against a
360 major human pathogen. We reveal layers of immunological redundancy likely to mask
361 the contribution of MAIT cells in many situations of infectious challenge, but suggest a
362 critical role for MAIT cells becomes apparent in a crisis situation – as reflected here in a
363 high infecting inoculum, or in the face of compromised specific immunity – in which the
364 gulf between survival and death is finely balanced. Moreover, we demonstrate the
365 mechanism of this MAIT cell protection is IFN-γ dependent and enhanced by GM-CSF.
366 Due to the pleiotropic roles of IFN-γ and the conservation of the riboflavin pathway
367 across many species, this mechanism is likely broadly effective against other major
368 human intracellular pathogens, and may prove as relevant to the later stages of infection
369 as to the initial, acute phase characterized by innate immune responses countering rapid
370 pathogen replication. We have shown this immunity can be augmented by exposure to

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

371 MR1 ligands suggesting this mechanism might have potential for preventive or
372 therapeutic benefit.
373

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

374 **Materials and Methods**

375 *In vitro* activation assays

376 Jurkat cells expressing a MAIT TCR comprising the TRAV1-2-TRAJ33 α-chain
377 and TRBV6-4 β-chain (Jurkat.MAIT) were co-incubated at 10^5 cells per well in 96-well
378 U-bottom plates with an equal number of class I reduced (C1R) antigen presenting cells
379 (APCs) expressing MR1 (C1R.MR1)[3] for 16 h in RPMI-1640 media (Gibco) in
380 supplement and 10% foetal calf serum (FCS)) (RF10) media at 37°C, 5%CO_2. Cells were
381 stimulated for 16 h with bacterial lystates prepared using repeated ultrasonication of
382 bacteria in log-phase growth. Cells were stained with anti-CD3-APC and anti-CD69-PE
383 Abs and 7AAD before flow cytometric analysis. Activation of Jurkat.MAIT cells was
384 measured by an increase in surface CD69 expression.
385
386 For human MAIT cell assays, peripheral blood mononuclear cells (PBMCs) were
387 stained with anti-CD3-PEAF594, CD161-PECy7, TCR Vα7.2 (TRAV1-2)-APC. Vα7.2+
388 cells were enriched with anti-APC magnetic beads and the CD3+Vα7.2+CD161+
389 population were isolated by flow cytometry and cultured at 10^4 cells/well for 16 or 36
390 hours in penicillin-free media containing streptomycin and gentamicin with 5x10^4 THP1
391 cells which had been first infected for 3 hours (CD69 assays) or 27 hours (intracellular
392 cytokine staining) with different multiplicities of infection (MOI) of live *L. longbeachae*
393 NSW150. Control wells contained 5-OP-RU 10nM or *L. longbeachae* NSW150 at MOI
394 100 which had been heat killed for 10 minutes at 67°C. CD69 upregulation was measured
395 by surface staining for CD69-APCCy7 and 5-OP-RU loaded human MR1 tetramer-PE.
396 For intracellular cytokine expression cells brefeldin A was added for the last 16 hours,

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

397 cells fixed, permeabilized (using BD Fixation/Permeabilization Kit (BD, Franklin Lakes,
398 NJ) and stained with MR1 tetramer, CD3-PEAF594, Zombie yellow, IFNγ-FITC, and
399 TNFα-Pacific blue.

400

401 Generation of THP1:MR1- cell line

402 THP1:MR1- cell lines were generated by targeted deletion of MR1 using
403 LentiviralCRISPRv2 which was a gift from Feng Zhang (Addgene plasmid # 52961)[37].
404 The plasmid was digested with *BsmB1* (Fermentas), dephosphorylated and purified using
405 gel electrophoresis and the Ultraclean DNA isolation kit (MO Bio laboratories, Carlsbad
406 CA). Short guide RNAs (ACCTCTCATCATTGTGTTAA) were ligated and the reaction
407 product used to transform Stbl3 *E.Coli.* DNA was purified from transformed colonies
408 (QIAprep spin miniprep) and used to transfect HEK293T cells with LentiviralCRISPRv2
409 vector and packaging vectors. Supernatants were used to transduce parent THP1 cells and
410 cells were selected using puromycin resistance and single cell sorting using anti-MR1
411 antibody (8F2.F9) after upregulation of MR1 using acetyl-6FP. MR1 knockouts were
412 then verified using surface staining and western blotting.

413

414 Immunofluorescence microscopy

415 8 μm sections of cryopreserved, unfixed lung tissue were submerged into ice-cold
416 acetone for 10 min, air dried and then re-hydrated in PBS for 10 min. Endogenous biotin
417 block was performed using Biotin/Avidin blocking kit (Thermo Fisher, Waltham MA)
418 according to the manufacturer's instructions. Serum-free protein block (DAKO,
419 Carpinteria, CA) was applied for 15 min, followed by 30 min blocking with 10% normal

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

420 donkey serum. Sections were subsequently blocked with Murine MR1-6FP tetramer (Nil
421 PE) for 1 hour at room temperature. Murine MR1-5-OP-RU tetramer-PE (25 μg/ml in 2%
422 bovine serum albumin/PBS) was applied for 1 h at room temperature in the dark, sections
423 washed with PBS, fixed with 1% paraformaldehyde for 10 min, washed again and stained
424 with a cocktail containing polyclonal rabbit anti-Legionella antibody (gift from Dr
425 Hayley Newton, Department of Microbiology and Immunology, University of
426 Melbourne) and Goat anti PE (KPL). After 1 hr, sections were washed and stained with
427 Donkey anti Goat-AlexaFluor 568 (Life Technologies), Donkey-anti-Rabbit-DyLight 680
428 (Life Technologies) and Alexa Fluor 647-conjugated Rat anti mouse TCR-β (Biolegend).
429 Nuclei were counterstained with Hoechst 33342 (Life Technologies). Sections were
430 mounted with Prolong Gold mounting medium (Life Technologies). Image acquisition
431 was performed on Zeiss LSM 710 confocal microscope using Zen software (Zeiss,
432 Oberkochen, Germany) The resultant images were further analysed using FIJI Image J
433 software[38] (UW-Madison).

434

435 Animal models

436 Mice were bred and housed in the Biological Research Facility of the Peter Doherty
437 Institute (Melbourne, Victoria, Australia). MR1-/- mice were generated by breeding
438 Va19iCa-/-MR1-/- mice[39] (from Susan Gilfillan, Washington University, St Louis School
439 of Medicine, St Louis, MO) with C57BL/6 mice and inter-crossing of F1 mice. The
440 genotype was determined by tail DNA PCR at the MR1 locus as previously described[13].
441 Granzyme A/B-/- and Perforin-/- mice were purchased from Joe Trapani (Victorian
442 Comprehensive Cancer Centre, Melbourne). GK1.5 mice were crossed onto the MR1-/-

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

443 background to generate GK1.5.MR1-/- mice which lack CD4+ cells and MAIT cells.
444 Male mice aged 6–12 weeks were used in experiments, after approval by the University
445 of Melbourne Animal Ethics Committee (1513661).

446

447 Intranasal infection

448 Intranasal (i.n.) inoculation with *L. longbeachae* or antigens (76 pmol 5-OP-RU) and
449 TLR agonist (either 20 mg CpG or 20nmol Pam2Cys) in 50 µl per nares was performed
450 on isofluorane-anesthetized mice. For blocking experiments, mice were given 250 µg
451 anti-MR1 (26.5 or 8F2.F9)[21,40] or isotype control mAbs in 200 µl PBS, once (i.v or
452 intraperitoneally) 1 day prior to inoculation and three times (d1, d3, d5) post inoculation.
453 Mice were killed by CO_2 asphyxia, the heart perfused with 10ml cold RPMI and lungs
454 were taken.

455

456 To prepare single-cell suspensions lungs were finely chopped with a scalpel blade
457 and treated with 3mg/ml-1collagenase III (Worthington, Lakewood, NJ), 5 µg/ml
458 DNAse, and 2% fetal calf serum in RPMI for 90 min at 37°C with gentle shaking. Cells
459 were then filtered (70µm) and washed with PBS/2% foetal calf serum. Red blood cells
460 were lysed with hypotonic buffer TAC (Tris-based amino chloride) for 5 min at 37°C.
461 Approximately $1.5x10^6$ cells were filtered (40µm) and used for flow cytometric analysis.

462

463 Determination of bacterial counts in infected lungs.

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

464 Bacterial colonization was determined by counting colony-forming units (CFU)
465 obtained from plating homogenized lungs in duplicate from infected mice (x5 per group)
466 on buffered charcoal yeast extract agar containing 30μg/ml streptomycin and colonies
467 counted after 4 days at 37°C under aerobic conditions.

468

469 Adoptive transfer

470 As MAIT cell frequencies are low in naïve C57BL/6 mice, prior to adoptive transfer
471 experiments MAIT cell populations were expanded by intranasal infection with 10^6 CFU
472 *S.* Typhimurium BRD509 in 50μl PBS for 7 days as previously described[13]. After 7 days,
473 mice were sacrificed, single cell suspensions prepared and live CD3+CD45+MR1-5-OP-
474 RU tetramer+ cells sorted using a BD FACS Aria III. 10^5 MAIT cells were injected into
475 the tail veins of recipient mice which then received 0.1 mg each of anti-CD4 (Gk1.5) and
476 anti-CD8 (53.762) mAb i.p on days 2 and 5 or 6 to control residual conventional T cells.
477 Mice were rested for 2 weeks post transfer to allow full expansion of the MAIT cell
478 population prior to subsequent infectious challenge. Mice were weighed daily and
479 assessed for visual signs of clinical disease, including inactivity, ruffled fur, labored
480 breathing, and huddling behavior. Animals that had lost ≥20% of their original body
481 weight and/or displayed evidence of pneumonia were euthanized.

482

483 Statistical analysis

484 Statistical tests were performed using the Prism GraphPad software (version 7.0 La
485 Jolla, CA). Comparisons between groups were performed using Student's t-tests or
486 Mann-Whitney tests as appropriate unless otherwise stated. Survival curves were

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

487 compared using the Gehan-Breslow-Wilcoxon method for multiple groups. Flow
488 cytometric data analysis was performed with FlowJo10 software (Ashland, OR).

489 Reagents

490 Human peripheral blood mononuclear cells (PBMC) were obtained from the
491 Australian Red Cross Blood Service (ARCBS) (University of Melbourne Human
492 Research Ethics Committee 1239046.2). Healthy human lung explant tissue was obtained
493 via the Alfred Lung Biobank program and ARCBS from organs not suitable for donation
494 (Blood Service HREC 2014#14 and University of Melbourne Human Research Ethics
495 Committee 1545566.1).

496

497 Compounds, immunogens and tetramers

498 5-OP-RU was prepared as described previously[18]. CpG1688 (Sequence:
499 T*C*C*A*T*G*A*C*G*T*T*C*C*T*G*A*T*G*C*T (*phosphorothioate linkage)
500 nonmethylated cytosine-guanosine oligonucleotides was purchased from Geneworks
501 (Thebarton, Australia). Murine and human MR1 and β2-Microglobulin genes were
502 expressed in *Escherichia coli* inclusion bodies, refolded, and purified as described
503 previously[41]. MR1-5-OP-RU tetramers were generated as described previously[4].

504

505 Bacterial strains

506 Cultures of *Legionella pneumophila* JR32 and *Legionella longbeachae* NSW150
507 were grown at 37°C in buffered yeast extract (BYE) broth supplemented with 30-
508 50μg/ml streptomycin for 16 hour to log-phase (OD600 0.2-0.6) with shaking at 180 rpm.

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

509 For the infecting inoculum, bacteria were re-inoculated in prewarmed medium for a
510 further 2–4 h culture (OD_{600} 0.2–0.6) with the estimation that 1 OD_{600}=5x10^8/ml,
511 sufficient bacteria were washed and diluted in phosphate buffered saline (PBS) with 2%
512 BYE for i.n. delivery to mice. A sample of inoculum was plated onto BYCE with
513 streptomycin for verification of bacterial concentration by counting colony-forming units.
514
515 For infection of adoptive transfer donor-mice with *Salmonella* Typhimurium
516 BRD509 cultures were prepared as previously described[13].
517
518 Antibodies and flow cytometry
519 Antibodies against murine CD4 (GK1.5, APC-Cy7), CD19 (1D3, PerCP-Cy 5.5),
520 CD45.2 (104, FITC), IFNγ (XMG1.2, PE-Cy7), Ly6G (IA8, PECy7), TCRβ (H57-597,
521 APC or PE), TNF-α (MP6-XT22, PE), GM-CSF (MP1-22E9, PE) and IL-17A (TC11-
522 18H10, PE) were purchased from BD (Franklin Lakes, NJ). Antibodies against CD8a
523 (53-6.7, PE), PLZF (Mags.21F7, PE), RORγt (B2D, APC), T-bet (4B10, PE-Cy7) and
524 MHCII (M5/114.15.2, AF700) were purchased from eBioscience (San Diego, CA). Abs
525 against CD19 (6D5, BV510), F4/80 (BM8, APC), CD11b (M1/70, FITC), CD11c (N418,
526 BV786), CD31 (PCAM, MEC13.3, PerCPCy5.5), CD62L (Mel-14, FITC), CD64 (X54-
527 5/71, BV711), CD146 (ME-9F1, PerCPCy5.5), CD326 (G8.8, EpCAM, APC-Cy7) were
528 purchased from Biolegend (San Diego, CA). Blocking Ab (26.5, 8F2.F9) and isotype
529 controls (3E12, 8A5) were prepared in house. To block non-specific staining, cells were
530 incubated with MR1-6FP tetramer and anti-Fc receptor (2.4G2) for 15 min at room
531 temperature and then incubated at room temperature with Ab/tetramer cocktails in

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

532 PBS/2% fetal calf serum. 7-aminoactinomycin D (5 μl per sample) was added for the last
533 10 min.
534
535
536 Antibodies against human CD3 (UCHT1, PE-AlexaFluor594), TCR-Vα7.2 (3C10,
537 APC), CD161 (HP-3G10, PE-Cy7), TNF-α (Mab11, Pacific Blue), and viability dye
538 (Zombie Yellow) were purchased from Biolegend. Antibodies against IFNγ (25725.11,
539 FITC) and CD69 (FN50, PE) were purchased from BD, and anti-CD3 (UCHT1, APC)
540 from eBioscience.
541
542 Cells were fixed with 1% paraformaldehyde prior to analysis on LSRII or LSR
543 Fortessa or Canto II (BD Biosciences) flow cytometers. For intracellular cytokine
544 staining Golgi plug (BD Biosciences) was used during all processing steps. Cells
545 stimulated with PMA (phorbol 12-myristate 13-acetate;)/ionomycin (20 ng/ml, 1μg/ml,
546 respectively) for 3 h at 37°C were included as positive controls. Surface staining was
547 performed at 37°C, and cells were stained for intracellular cytokines using the BD
548 Fixation/Permeabilization Kit (BD, Franklin Lakes, NJ) or transcription factors using the
549 transcription buffer staining set (eBioscience) according to the manufacturers'
550 instructions.
551

661 ## Acknowledgments

662 This research was supported by National Health and Medical Research Council of
663 Australia (NHMRC) Program Grants 1113293, 1016629 and 606788, a Project Grant
664 1120467 as well as a Merieux Research Grant. T.S.C.H. was supported by a Wellcome
665 Trust Postdoctoral Research Fellowship (104553/z/14/z). A.J.C. was supported by an
666 ARC Future Fellowship. S.B.G.E. was supported by an ARC DECRA Fellowship. J.R.
667 was supported by an NHMRC Australia Fellowship, D.P.F. was supported by an
668 NHMRC Senior Principal Research Fellowship. H.W. is supported by a Melbourne
669 International Engagement Award (University of Melbourne). C.D'S. is supported by a
670 Melbourne International Research Scholarship and a Melbourne International Fee
671 Remission Scholarship (University of Melbourne). We thank Dr Wei-Jen Chua and Prof
672 Ted Hansen for their kind provision of 8F2.F9 and 26.5 mAbs, and Prof David Jackson
673 for Pam2Cys. We are grateful to Prof Francis Carbone for critical review of the
674 manuscript.

675 ## Author contributions

676 HW, CDS, TSCH, XYL, LK, TLP, SBG, BSM, ZC, AWS performed the experiments
677 and analyzed the data. ZC, TSCH, HW, JM, AC, RS designed the experiments and
678 managed the study. NW, DPF, YI, JG, GW, LK-N, JR, LL, JYWM provided essential
679 reagents and intellectual input. TSCH, AC, ZC, JM conceived the work and wrote the
680 manuscript which was revised and approved by all authors.

681 **Competing Financial Interests**

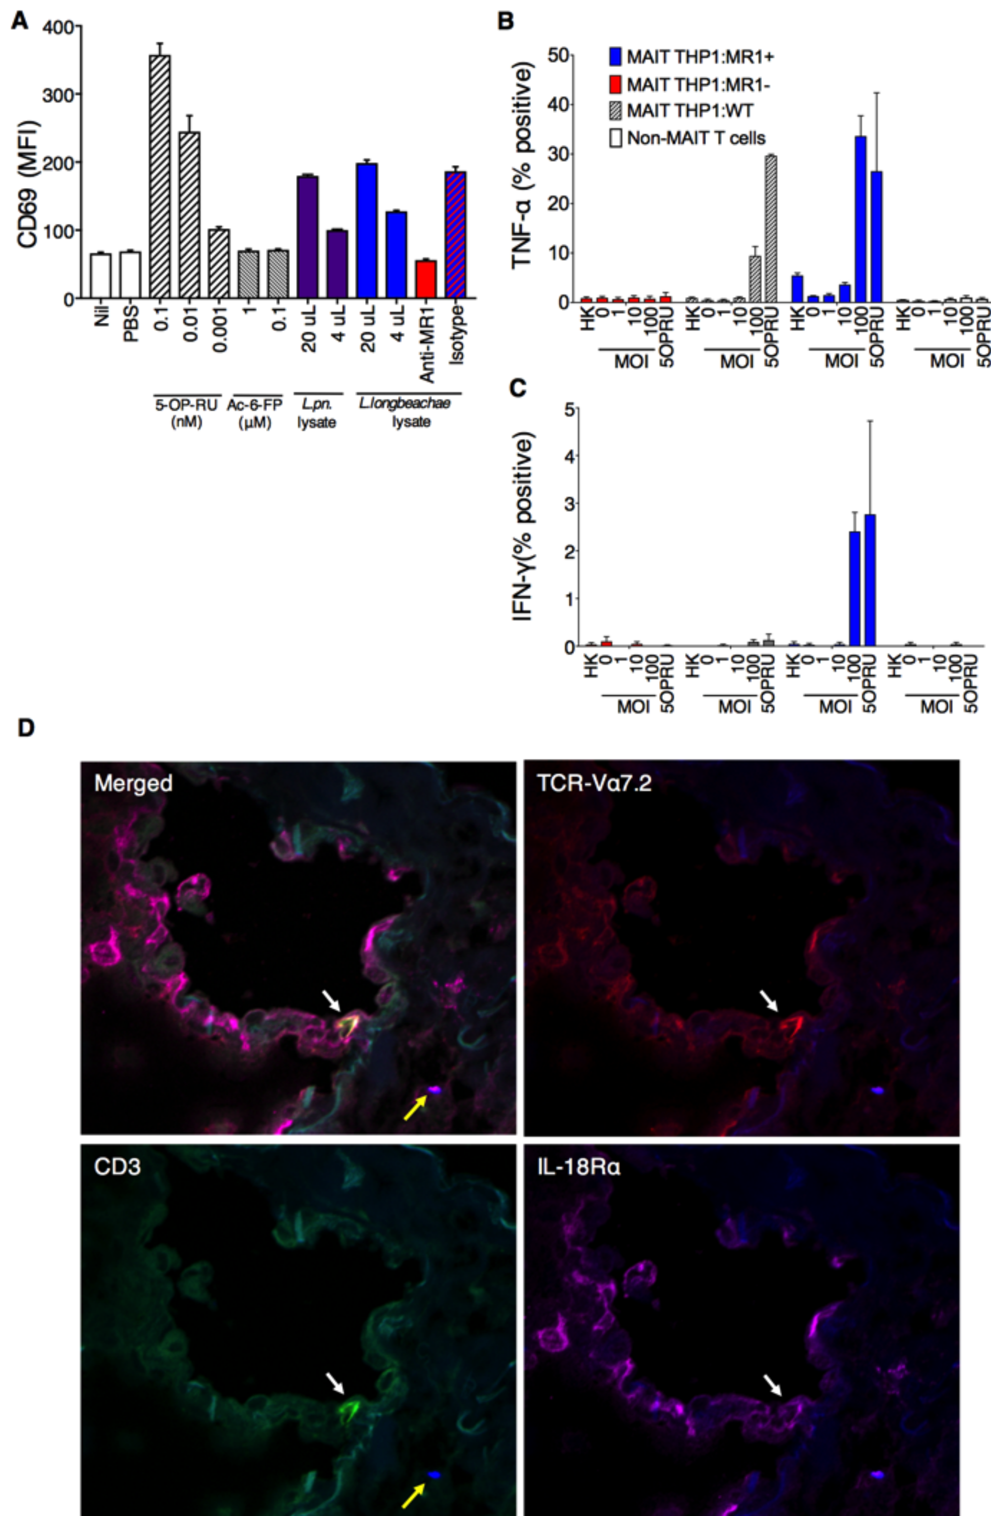
689 # Figures



690

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

691 **Figure 1. Human MAIT cells are activated by *Legionella* infection via MR1 *in vitro***

692 (**A**) Jurkat.MAIT and C1R.MR1 cells were co-incubated for 16h with lysates of *L.*
693 *pneumophila (L. pn.) or L. longbeachae,* or 5-OP-RU, acetyl-6-FP or PBS. Activation,
694 detected by staining with anti-CD69, is enhanced by bacterial lysate or by the activating
695 ligand 5-OP-RU, but not by acetyl-6-FP. Activation was blocked by anti-MR1 antibody
696 (26.5) but not by isotype control (W6/32) 2h prior to co-incubation. (**B-C**) THP1 cells
697 (WT) or THP1 cells overexpressing MR1 (THP1:MR1+, blue) or deficient in expression
698 of MR1 (THP1:MR1-, red) were infected for 27h with *L. longbeachae*, heat killed (HK)
699 *L. longbeachae* (MOI100) or 10nM 5-OP-RU, then co-cultured for 16h with
700 $CD3^{+}V\alpha7.2^{+}CD161^{+}$ human peripheral blood MAIT cells, or MAIT-depleted
701 conventional T cells. MR1-5-OP-RU-tetramer+ MAIT cell activation was measured by
702 intracellular cytokine staining for (**B**) TNF-α or (**C**) IFN-γ. (**D**) Immunofluorescence
703 micrographs showing CD3+TCRVα7.2+IL-18Rα+ MAIT cell (white arrow) within
704 healthy human lung tissue 24h post infection *ex vivo* with *L. longbeachae* (yellow arrow).
705 Red, TCR-Vα7.2; green, CD3; magenta, IL-18Rα; blue, legionella. Data show MFI or
706 percentage cytokine-positive cells with SEM.

709

710 **Figure 2. Murine pulmonary infection with *Legionella* induces long-lasting**

711 **expansion of MAIT cells *in vivo***

bioRxiv preprint doi: https://doi.org/10.1101/231472; this version posted December 9, 2017. The copyright holder for this preprint (which was not certified by peer review) is the author/funder. All rights reserved. No reuse allowed without permission.

712 (**A**) Immunofluorescence micrographs of murine lungs showing TCRβ+MR1-5-OP-RU-
713 tetramer+ MAIT cells (white arrows) adjacent to infected cells (yellow arrows) within
714 parenchyma four days after intranasal infection with $2x10^4$ CFU *L. longbeachae* in
715 C57BL/6 mice which had been challenged with the same inoculum 5 months previously.
716 (**B**) Flow-cytometry plots showing MAIT cell percentage among TCRβ+ lymphocytes in
717 the lungs of C57BL/6 mice either uninfected or infected with 10^3, 10^4 or 10^5 CFU *L.*
718 *longbeachae* for 7 days. Relative (**C**) and absolute (**D**) numbers of MAIT cells and
719 conventional αβ T cells 7 days post infection. Absolute numbers (**E**), and relative
720 percentages (**F**) of MR1-tetramer+ MAIT cells or conventional αβ T cells in C57BL/6
721 and MR1-/- mice after intranasal infection with $2x10^4$ CFU *L. longbeachae.* Experiments
722 used 4-6 mice per group (mean±SEM) and were performed twice with similar results. B6,
723 C57BL/6 mice; CFU, colony forming units; DAPI, 4',6-diamidino-2-phenylindole.
724 Statistical tests C: ** Dunnett's P<0.01, **** P<0.0001; C all comparisons with the
725 respective naïve groups P<0.0001 for Dunnett's on log transformed data. See also
726 Figures S1, S2.

729 **Figure 3. Profiles of MAIT cell cytokine expression and nuclear transcription**
730 **factors vary over the course of pulmonary *Legionella* infection**

731 (**A**) Flow cytometry plots showing intracellular staining for IL-17A, IFN-γ and GM-CSF
732 by pulmonary TCRβ lymphocytes (non-MAIT conventional and MAIT cells) after 4h
733 culture with or without PMA/ionomycin with bredeldin A. TCRβ+ lymphocytes were
734 harvested from lungs of C57BL/6 mice infected with $2x10^4$ CFU *L. longbeachae* for 7
735 days. Percentages in brackets represent the proportion of MR1-tetramer positive MAIT
736 cells expressing cytokine. (**B**) Percentages of pulmonary MAIT cells producing IL-17A,
737 IFN-γ or GM-CSF by intracellular staining, directly *ex-vivo* from C57BL/6 mice infected
738 for 0, 7 or >100 days with $2x10^4$ CFU *L. longbeachae*. Experiments using 4-7 mice per
739 group (mean±SEM) were performed twice with similar results. (**C**) Expression of T-bet
740 and RORγt in MAIT cells from uninfected or infected C57BL/6 mice 7 or >100 days post
741 infection (DPI). (**D**) Average proportion of T-bet+, double positive (DP), RORγt+ and
742 double negative (DN) MAIT cells from uninfected or infected C57BL/6 mice at indicated
743 date. Mean values are representative of 5-8 mice in each group. See also Figure S3.
