30 **Abstract**

31 Androgen signaling plays a pivotal role in spermatogenesis, but the molecular
 32 mechanisms underlying androgen action in this process are unclear. Specifically, it is
 33 unknown if the androgen receptor (AR) is expressed in germ cells. Thus it's interesting
 34 to reveal how androgen induces differentiation of spermatogonial progenitor cells (SPCs)
 35 in the niche. Here we observed the AR is primarily expressed in pre-spermatogonia of
 36 mice 2 days post partum (dpp), absent before spermatogenesis onset, and then
 37 expressed in surrounding Sertoli cells. Then we examined a regulatory role of the AR in
 38 spermatogenesis using a SPCs-Sertoli cells co-culture system, and demonstrated that
 39 androgen negatively regulated *Plzf* (the gene for stemness maintenance of SPCs).
 40 Additionally, we identified Gata2 as a target of AR in Sertoli cells, and demonstrated that
 41 Wilms tumor 1 (WT1) and β 1-integrin as two putative intermediate molecules to transfer
 42 differentiation signals to SPCs, which was further verified using androgen
 43 pharmacological-deprivation mice model. These results demonstrate a regulatory
 44 pattern of androgen in SPCs niche in an indirect way via multiple steps of signal

transduction.

Introduction

Spermatogonial stem cells are the original source for developing functional sperms in male testis, which reside in the basement membrane and being under the control of their microenvironment. Androgens are produced by testicular Leydig cells and functions via binding and activation of its receptor AR in cytoplasm. Activated AR is subsequently imported into nucleus after release of heat shock protein and functions as a transcription factor^{1,2}. Numerous target genes of AR have been identified, involving in many biological processes such as gonad development³ and tumorigenesis⁴. However, the exact biological mechanism of AR in spermatogenesis is not fully understood, and if AR is expressed in testicular germ cells is still unclear. Some earlier studies have detected AR expression in germ cells of mouse testis^{5,6}. Other studies suggested that AR was presented only in the somatic cells in rodent testes⁷. It has been shown that germ cell specific AR knockout mice still had normal sperm⁸ but conditional deletion of AR in Leydig and Sertoli cells caused spermatogenesis defects^{9,10}. These results suggests that AR expression in Sertoli cells, Leydig cells and perivascular myoid cells may participate in spermatogenesis via interacting with Sertoli cells surrounding spermatogonia¹¹. However, Sycp1-driven Cre for AR deletion in germ cells was used in the study mentioned above⁸, which only indicates AR is not required in germ cells since meiosis onset. The exact mechanism between androgen and spermatogenesis still needs to be further investigated.

Promyelocytic Leukemia Zinc Finger (*Plzf*) is an important transcription suppressor gene for SSCs maintenance. It was first discovered by its association with acute promyelocytic leukemia¹², and was subsequently characterized as an undifferentiated marker for SSCs in rodents¹³, primates¹⁴ and livestock¹⁵. Loss of *Plzf* did not impact spermatogonia formation in embryonic and neonatal stages, but led to progressive and significant deficiency of SSCs after neonatal life and finally caused infertility^{13, 16}, indicating its critical role in SSCs maintenance. Moreover, PLZF expression was detected in spermatogonia A_s , A_{pr} and A_{al} , not restricted in SSCs¹⁷. Thus, PLZF⁺ population represents undifferentiated spermatogonia pool in testis, and PLZF is an important factor for maintenance of this pool^{18, 19}. Although the interaction of androgen and PLZF has not been reported in germ cells, many evidence from prostate tumorigenesis studies suggest interaction between AR and PLZF. For example, *Plzf* has been shown to repress prostate tumorigenesis and its expression can be inhibited by androgen antagonist, bicalutamide²⁰. In prostate cancer cell line PCa cells, PLZF was identified as a repressor of AR as well as an activator of regulated in development and DNA damage responses 1 (REDD1), which suppressed mTORC1²¹. AR was characterized as a critical transcriptional factor in prostate tumorigenesis⁴, and mTORC1 has been found to participate in EMT (Eepithelial mesenchymal transition) in prostate cancer²². Thus, PLZF functions as tumor suppressor and interacts with AR in prostate cancer system, but it's uncertain whether similar links exist in germ line. In rodent testis, Sertoli cells in base membrane form niches to protect SSCs and to regulate their fates²³, and many surface proteins, such as cadherins and integrins, have

been identified as functional components in this microenvironment²⁴. Many of these molecules have been reported to be AR responsive and thus regulate the fate of SSCs²⁵, but the mechanism is still largely unknown.

To understand androgen's role in Sertoli cells, it's necessary to focus on the Wilms' tumor 1 gene (*Wt1*), which is specifically expressed in mouse Sertoli cells and is required for Sertoli cell lineage maintenance^{26, 27}. Moreover, WT1 functions as a suppressor of *Ar*²⁸. Thus, we wonder whether WT1 participates in the regulation of spermatogenesis mediated by androgen signal.

To elaborate androgen's regulatory mechanism in spermatogenesis, we studied AR expression pattern during postnatal testis development using a monoclonal antibody. Weak AR signal was detected in pre-spermatogonia of 2 dpp testes but not in surrounding somatic cells, however, from 3 dpp all signals were detected exclusively in somatic cells. Spermatogenesis starts from about 5 dpp²⁹, so the possibility that germ cells need AR for spermatogenesis is eliminated. In vitro experiments further confirmed this conclusion, thus we investigated the indirect regulation pattern of androgen on SSCs differentiation via Sertoli cells using a SSCs-Sertoli cells co-culture system. Two transcription factors Gata2 and WT1 were identified as AR's downstream targets in Sertoli cells. Moreover, a surface protein β 1-integrin was subsequently regulated by WT1 and may function as an intermediate molecule to transfer androgen signal from Sertoli cells to SSCs to regulate spermatogenesis. In all, this study demonstrates the complicated regulation pattern of androgen in spermatogenesis in SSCs niche, which

requires the cooperation of Sertoli cells and many intermediate molecules to regulate *Plzf* expression in undifferentiated spermatogonia population.

Results

PLZF⁺ spermatogonia pool keeps steady during testis development

Due to PLZF is a specific marker for undifferentiated spermatogonia, population size of PLZF⁺ cells in mouse testis determines the capacity of self-renewal and spermatogenesis in seminiferous tubules. Our immunohistochemistry results demonstrated that from neonatal to adult testes, all PLZF⁺ cells exclusively located at basement membrane with strong nucleus staining [Fig.1A-D], or a few oblate pairs of cells in adult testes, which are A_{pr} spermatogonia [Fig.1D inset]. These PLZF⁺ cells were surrounded by Sertoli cells, which formed the niches for SSCs. Strong PLZF intensity in 5 dpp testis indicated high expression level of PLZF at this stage. In testes from 5 to 42 dpp, the percentage of PLZF⁺ cells in seminiferous tubules was declined [Fig.1Q] due to continuous production of differentiated germ cells. However, the total number of PLZF⁺ cells was approximately consistent [Fig.1R], indicating a stable pool of undifferentiated spermatogonia during testicular development.

AR expression in testis indicates an indirect regulation pattern in promoting spermatogenesis

To investigate the function of androgen during spermatogenesis, we examined AR expression pattern in neonatal (5 dpp), juvenile (10 dpp), puberty (20 dpp) and adult (42

dpp) testes using immunohistochemistry. Intensive AR signals were detected in Sertoli cells, Leydig cells and myoid cells but not in germ cells [Fig.1 E-H], consistent with previous report that postnatal testicular germ cells lacked endogenous AR⁷. In 5 dpp testes, moderate AR staining was detected in Sertoli cells localized at basement membrane [Fig.1 E]. Both AR⁺ Sertoli cells number and AR signal intensity were obviously increased in 10 dpp testes, and some AR⁺ Sertoli cells moved to the second layers [Fig.1 F], and then formed AR⁺ layers in 20 dpp testes [Fig.1 G]. In 42 dpp testis, those AR⁺ second layers disappeared and AR⁺ cells distributed in different layers of seminiferous tubules [Fig.1 H]. In rodent Sertoli cells, AR expression was reported to start from 3-5 dpp^{30, 31}, thereupon we examined AR expression in 2, 3 and 4 dpp testes, and detected AR signal in Sertoli cells only from 3 dpp testis and signal intensity grew stronger from 5 dpp [Fig.1I-K]. We also noticed Sertoli cells did not express AR in 2 dpp testis as literature reported³¹, but we unexpectedly observed weak AR signal in pre-spermatogonia localized in the cord of testes [Fig.1I]. Interestingly, AR signal was absent in the pre-spermatogonia of 3 dpp testes, at which time point some of these pre-spermatogonia had already migrated from cord to basal membrane [Fig. 1J]. Meanwhile, Sertoli cells began to express AR and two AR⁺ Sertoli cells embraced one pre-spermatogonium to form a special structure nominated as 'niche' [Fig.1J-L], implying AR in Sertoli cells commenced to function in microenvironment. It's known that spermatogenesis starts from 3-5 dpp and differentiated spermatogonia can be observed at 6 dpp²⁹. Dual immunofluorescent staining also exhibited no overlap of AR and PLZF signals in 4 days testes [Fig.1 M-P]. Collectively, AR expression pattern in Sertoli cells

demonstrates their close connection with PLZF⁺ cells, but PLZF⁺ population is unable to be directly stimulated by androgen since they lack of endogenous AR when spermatogenesis starts.

Blocking of androgen by antagonist inhibits SSCs differentiation

To investigate the role of androgen in spermatogenesis, a co-culture system of testicular cells was established. Testes from 5 dpp mice (this time spermatogenesis just begins) were harvested and digested to single cells (composed of SSCs, differentiating spermatogonia and testicular somatic cells) and cultured on dishes. Somatic cells attached to gelatin and formed flat layers within 12 hours' culture, and undifferentiated spermatogonia population including SSCs attached on these layers [Fig.2A]. This total testicular cells co-culture system can be maintained in vitro for 4 passages (16 days) at least [Fig.2B]. Moreover, this co-culture system stably expressed germ line markers and somatic markers [Fig.S1A-V], and was sensitive to dihydrotestosterone (DHT) or bicalutamide (an efficient AR antagonist) stimulation [Fig.S1W], indicating spermatogonia (including SSCs) and Sertoli cells were well maintained in this system and can be used to mimic spermatogenesis in vitro. To study androgen's function in spermatogenesis in vitro, total testicular cells from 5dpp testes were plated on dishes, and 16 hours later DHT was supplied to culture medium, and 2 hours later bicalutamide was supplied to corresponding samples. After 48-hour incubation, more A_{al} stage spermatogonia were observed in DHT treated group while more SSCs clusters remained in bicalutamide treated group [Fig.2C-E]. RT-PCR

revealed DHT stimulation caused decreased expression levels of *Id4*, *Gfra1* and *Plzf* [Fig. 2F], indicating reduced size of undifferentiated spermatogonia populations including A_s , A_{pr} and A_{al} , while expression level of c-kit was significantly increased [Fig. 2F]. Notably, expression of *Tex14*, a marker of intercellular bridge existing in both mitotic and meiotic divisions, namely from A_{pr} , A_{al} spermatogonia, to spermatocytes³², was up-regulated after DHT treatment [Fig. 2F]. Combined with observations above, we concluded that DHT caused a reduced size of undifferentiated spermatogonia populations, and accordingly proposed that androgen promoted differentiation of spermatogonia in this in vitro system. Results from western blot revealed expression levels of AR displayed opposite responses to those of PLZF after DHT/bicalutamide treatment [Fig. 2G]. Additionally, we observed that DHT aggravated down-regulation of PLZF expression induced by siRNA [Fig. 2H], which further confirmed that DHT promoted SSCs differentiation. On the contrary, Thy1-MACS purified SSCs cultured on gelatin or mitotically inactivated STO feeder layer (negative of AR expression) showed no obvious phenotype change after either DHT or bicalutamide treatment (data is not shown), suggesting Sertoli cells were necessary for SSCs differentiation during androgen stimulation.

AR indirectly regulates *Wt1* in Sertoli cells

To reveal regulatory mechanism of AR on spermatogenesis, we used ChIP-seq to screen the target genes of AR in purified Sertoli cells from 5 dpp mouse testis. In the candidates of targets, we noticed that *Gata2* promoter was a binding region of AR (p-value <0.01 by MACS³³) [Fig.3A]. This result provided an important cue, since

Gata2 has been identified as a factor to promote WT1 expression by binding the enhancer of *Wt1*³⁴, and WT1 is a pivotal transcription factor for spermatogenesis in Sertoli cells³⁵. Then we did ChIP-qPCR to validate the binding of AR on *Gata2* [Fig. 3 B], and observed that AR negatively regulated expression of Gata2 and WT1 after DHT stimulation or AR overexpression in Sertoli cells [Fig.3C]. Consistently, knockdown of Gata2 caused down-regulated WT1 expression [Fig.3D]. Taken together, these results implied that AR indirectly regulated WT1 expression via Gata2.

The $\beta 1$ -integrin gene is a direct target of WT1 in Sertoli cells

As a pivotal transcription factor for spermatogenesis, WT1 involves multiple functions in Sertoli cells. Thus, we used ChIP-seq again to screen the potential target genes of WT1 in Sertoli cells. Notably, $\beta 1$ -integrin gene was identified as a direct binding target of WT1 [Fig. 4A]. Besides as a subunit of laminin receptor, $\beta 1$ -integrin is essential for SSCs homing since deletion of $\beta 1$ -integrin in SSCs or in Sertoli cells impaired SSCs homing²⁴, indicating its signal function in SSCs niche. After validated the binding of WT1 on $\beta 1$ -integrin gene by ChIP-qPCR [Fig. 4B], we further examined whether WT1 regulates $\beta 1$ -integrin expression at protein level. Knockdown of WT1 expression in testis somatic cells (SSCs removed) caused down-regulated $\beta 1$ -integrin expression [Fig. 4C], and WT1 overexpression strengthened $\beta 1$ -integrin's signal [Fig. 4D], suggesting $\beta 1$ -integrin expression was regulated by WT1. Moreover, we observed that androgen signal negatively regulated expression of $\beta 1$ -integrin in Sertoli cells [Fig. 4E], and disturbance of Gata2 expression displayed the same impact on $\beta 1$ -integrin expression [Fig. 3C],

which were consistent with aforementioned results that AR negatively regulated Gata2 by binding on its promoter region, and consequently interfered in WT1 expression. Then we interfered in β 1-integrin expression in co-culture system using siRNA and observed decreased expression level of PLZF [Fig.4F], implying the indispensable role of β 1-integrin in SSCs maintenance. Collectively, we preliminarily found a cue from androgen signal to surface protein β 1-integrin, via intermediate factor Gata2 and WT1 [Fig. 4G].

β 1-integrin on Sertoli cells may function as an intermediate molecule to regulate SSCs differentiation

The important role of β 1-integrin in vivo has been proven in Sertoli cells specific β 1-integrin conditional knockout mice²⁴. Here we used in vitro co-culture system to preliminarily investigate the role of β 1-integrin on Sertoli cells for SSCs maintenance. Because primary Sertoli cells have limited passage capacity in vitro, and knockout of β 1-integrin in Sertoli cells caused severe damage, we infected primary Sertoli cells with β 1-integrin shRNA or control shRNA lentivirus for 72 hours to attenuate β 1-integrin expression and used them as feeder layers for Thy1⁺ SSCs (Knockdown efficiency of β 1-integrin shRNA was evaluated in Fig. S2J-L). After co-culture for 48 hours, number of SSCs on Sertoli cells infected with β 1-integrin shRNA lentivirus was significantly less than that on control shRNA infected Sertoli cells [Fig. 5A], and western blot confirmed SSCs on β 1-integrin interfered feeder expressed reduced levels of SSCs markers [Fig. 5B], indicating that β 1-integrin on Sertoli cells affects maintenance of SSCs in this

co-culture system..Then we hypothesize that $\beta 1$ -integrin on Sertoli cells must interact with some molecules on SSCs to regulate their fates. To screen the molecules interacted with $\beta 1$ -integrin, expression of integrins and cadherins in SSCs were examined by RT-PCR [Fig. 5C]. We focused on E-cadherin as a candidate since SSCs highly and specifically express E-cadherin. Subsequently, the binding of $\beta 1$ -integrin and E-cadherin was validated in adult mouse testis lysates using immunoprecipitation. E-cadherin was pulled down by the antibody against- $\beta 1$ -integrin, and vice versa [Fig. 5D], implying that E-cadherin on SSCs binds with $\beta 1$ -integrin in physiological condition. However, different from E-cadherin as a specific undifferentiated spermatogonia marker, $\beta 1$ -integrin is expressed on both spermatogonia and Sertoli cells ^{36, 37}, which is consistent with our results from IF [Fig.5E,G and Fig. S3]. Thus, it's not clear that E-cadherin on SSCs binds with $\beta 1$ -integrin on Sertoli cells or on SSCs themselves. Therefore, thy1⁺ SSCs were used for IP [Fig. 5H], and the result eliminates the possibility that E-cadherin and ITGB1 on SSCs binds on themselves. These results suggest that $\beta 1$ -integrin on Sertoli cell is essential for SSCs maintenance, and probably binds with E-cadherin on SSCs as a putative interaction partner.

Pharmacologically androgen deprived mice are lack of differentiated germ cells but enriched with hyper-proliferated PLZF⁺ and $\beta 1$ -integrin⁺ spermatogonia

To further study the role of androgen on spermatogenesis, 33 6-week old male mice were intraperitoneally injected with bicalutamide, since mice in this age had mature

Sertoli cells, stable AR expression and continuous spermatogenesis. Bicalutamide recipient mice exhibited retarded body weight growth and smaller testis size compared to control group [Fig. 6A-B]. Histological results revealed the severe deficiency of differentiated germ cells (spermatocytes, spermatids and sperms) in seminiferous tubules [Fig. 6E-F]. Moreover, we observed reduced number of AR⁺ cells [Fig. 6D] and decreased expression level of AR [Fig.6G, H and R], but obvious increased number of PLZF⁺ cells [Fig.6C] and expression level of PLZF [Fig.6I, J and R] in bicalutamide recipient testes, indicating that deprivation of androgen did not impair undifferentiated spermatogonia population, but resulted in blockage of germ cell differentiation and expansion of undifferentiated spermatogonia population. Notably, in many seminiferous tubules of bicalutamide recipients, accumulated spermatogonia formed a second layer [Fig.6K], which were identified as PLZF negative [Fig.6M], β 1-integrin and c-kit positive [Fig.6N-O], and mitotically active [Fig.6P-Q] spermatogonia. These results indicated androgen deprivation blocked spermatogenesis at the step that ckit⁺ β 1-integrin⁺ spermatogonia differentiate to more differentiated populations, and consequently led to accumulation of undifferentiated spermatogonia, including PLZF⁺ population [Fig. 7A]. Western blot revealed enhanced expressions of Gata2, WT1 in bicalutamide recipients [Fig. 6R], which was consistent with results from in vitro system that androgen regulated Sertoli cells' function in spermatogenesis via Gata2 and WT1. Enhanced expressions of PLZF and β 1-integrin resulted from accumulated spermatogonia, and decreased expressions of Sycp3, Claudin-11 and Nectin-2 were consequence of lost meiotic germ cells caused by androgen deprivation [Fig.6R]. These results implied that blockage of

androgen in adult mouse testis inhibited the differentiation from spermatogonia to spermatocytes and promoted SSCs self-renewal involving multiple signal transductions in the niche. We will focus on how β 1-integrin of Sertoli cells interacts with SSCs to regulate SSCs differentiation in the future work.

Discussion

Our results exhibit SSCs lack of endogenous AR after 3 dpp, which is consistent with the dispensable role of AR in differentiated germ cells from AR germ cell conditional knockout mice. Interestingly, some studies detected AR expression in germ cells of fetal testis³⁸, and we examined weak AR signal in pre-spermatogonia of 2 dpp old testes. Therefore, we prefer the opinion that SSCs do not need endogenous AR after neonatal stage, and the function of AR in embryonic and new born stages is still need to be revealed.

Testis Zinc Finger Protein (TZFP), a homolog of PLZF, was reported to co-repress the activated AR³⁹ and may participate in hormone signal pathway to regulate spermatogenesis⁴⁰. However, IHC staining showed PLZF and AR staining were distributed in distinct cell types after neonatal stage, indicating no direct interaction between these two transcription factors during spermatogenesis. Based on our data, we hypothesize that androgen signal transduction in spermatogenesis spatially can be summarized into three steps [Fig. 7B]: the first step is AR activation in Sertoli cells induced by androgen, including androgen-AR interaction and activation of AR's

downstream genes to produce signal molecules; second step is the communication between Sertoli cells and SSCs, involving some surface or transmembrane proteins; the last one is signal transduction to SSCs nucleus to turn off PLZF and start differentiation. Our results suggest that AR inhibits *gata2* expression in Sertoli cells by binding on its promoter region, leading to subsequent decrease of WT1 expression, and WT1 binds and regulates $\beta 1$ -integrin in Sertoli cells, which interacts with SSCs as a putative signal molecule to regulate SSCs differentiation. WT1 is able to bind the promoter of *Ar* to inhibit AR expression²⁸. We revealed AR's inhibitory role on WT1 expression via interacting with Gata2, indicating a feedback regulation on WT1 expression. Moreover, we proposed $\beta 1$ -integrin on Sertoli cells as a regulatory molecule on SSCs differentiation. Routinely, $\beta 1$ -integrin combines with another subunit, i.e. $\alpha 1$ -integrin, $\alpha 6$ -integrin, to form a complex. On SSCs surface $\beta 1$ -integrin binds $\alpha 6$ -integrin to form laminin receptor, which is essential for SSCs maintenance. Nevertheless, it's not clear that $\alpha 6$ -integrin binds with $\beta 1$ -integrin in Sertoli cells⁴¹, thus we are interesting in searching for the interactive molecule of $\beta 1$ -integrin on Sertoli cells in future study. Moreover, although our data demonstrated that E-cadherin on SSCs binds $\beta 1$ -integrin on Sertoli cells, it's not clear E-cadherin really functions as a signal molecule to regulate SSCs fates in responding to $\beta 1$ -integrin on Sertoli cells, especially loss of E-cadherin in SSCs has been proven with unimpaired homing capacity. However, we can not conclude E-cadherin is redundant in SSCs, since SSCs enrich other types of cadherins which may compensate the role of E-cadherin, and that study also noticed that E-cadherin mutation in SSCs led slightly reduced colony formation after transplantation

²⁴. Moreover, E-cadherin was reported to be functional in transformation of SSCs into pluripotent status ⁴². Thus, in future work we will focus on the link of E-cadherin and SSCs fate, and will also screen β 1-integrin's other binding partners on SSCs surface related to signal reception and transmission to SSCs nucleus.

Two important junction proteins Claudin-11 and Nectin-2, which were reported to be significantly impacted in testes of AR knockout mouse ²⁵, were down-regulated in bicalutamide recipient testes. Claudin-11 is a pivotal component of tight junction (TJ) barrier and closely related to spermatogenesis, and its deficiency caused infertility ⁴³. *Ar* deletion in Sertoli cells resulted in down-regulation of Claudin-3 (a homolog of Claudin-11 and a component of TJ junction) and a subsequent increase of BTB (blood-testis barrier) permeability ⁴⁴. Further study revealed that Claudin-11 replaced Claudin-3 during spermatocyte translocation in spermatogenesis ⁴⁵. Therefore, we inferred that androgen deprivation caused the blockage of spermatogonia differentiation and a consequent accumulation of SSCs. Reduced Claudin-11 expression after androgen deprivation indicated loose of TJ junction. Whether Claudin-11 interacts with β 1-integrin is also an interesting question. Down-regulation of Nectin-2 after androgen deprivation from our experiments exhibited contradicting result to that from AR knockout mice ²⁵. As a pivotal anchor junction protein, Nectin-2 expression was mainly detected in Sertoli cells and elongated spermatids, and *Nectin-2* knockout mice had normal sperm titers but exhibited infertility phenotype due to serve spermatozoa malformation ⁴⁶, suggesting the major role of Nectin-2 is for sperm mature. Thus, the dramatic decline of

Nectin-2 expression in our androgen deprivation model was caused by blockage of spermatogonia differentiation into spermatocytes and spermatids.

This study reveals androgen signals pathway in Sertoli cells which promoting differentiation of PLZF⁺ spermatogonia population. Gata2, WT1 and β 1-integrin were identified as pivotal intermediate molecules in this process. In the future, we will focus on the communication pattern between Sertoli cells and SSCs, in particular β 1-integrin's role in regulation of SSCs fates.

Materials and Methods

Animals

CD-1 mice were supplied by Comparative Medicine Centre of Yangzhou University and all the procedures for animal experiments were approved by the ethical committee at Nanjing Agricultural University.

Isolation and culture of total testicular cells or SSCs

Testicular cells were extracted from testes of 5 dpp mice generally following previous protocol⁴⁷ with minor modifications. Testes were cut into small particles and followed by collagenase IV and trypsin digestion. Undigested collagen was removed using micropipettor after centrifugation, and cell pellet was resuspended in culture medium and then transferred to gelatin coated plates for incubation. For SSCs sorting,

resuspended cells after two-enzyme digestion were filtered with 70- μ m cell filter and subsequently incubated with mouse Thy-1.2 antibody coated magnetic beads (BD, Cat.551518). Thy1+ fraction was collected and cultured on mitotically inactivated STO feeder layer at 37 °C with 5% CO₂. Culture medium for total testicular cells or SSCs was composed of 90% MEMa, 10% FBS (Gibco), 1 ng/ml bFGF (Sino Biological Inc., 10014-HNAE), 1 ng/ml EGF (Sino Biological Inc., 50482-MNAY), 1 ng/ml GDNF (Sino Biological Inc., 10561-HNCH), 10 ng/ml LIF (santa, sc-4378), 20 μ g/ml transferrin (sigma, T8158), and 5 μ g/ml insulin (aladdin, I113907). For androgen stimulation or deprivation, dihydrotestosterone (sigma, cat. 31573) or bicalutamide (sigma, PHR-1678) was added to the culture medium accordingly 48 hours before cell harvesting. To make the feeder layer, STO cells were incubated with 10 μ g/ml mitomycin C (Roche, cat. 101074090001) at 37 °C with 5% CO₂ for 2 hours and plated on gelatin coated plates.

Sertoli cell isolation

A modified method was used to isolate Sertoli cells from testes of 6 dpp mice⁴⁸. Briefly, testes were encapsulated and seminiferous tubules were pooled and digested with 0.5mg/mL collagenase IV. After centrifugation, the supernatant containing the Leydig cells was pipetted out. The tubules were further digested with 1 mg/mL collagenase IV and 10 μ g/mL DNase to detach peritubular cells. Digestion was monitored under microscopy. The supernatant containing peritubular cells after centrifugation was discarded. Finally, single cell suspension was obtained after trypsin digestion and blocked by FBS. The cell pellet was resuspended in DMEM/F12 media supplemented

with 2.5% FBS, 5% horse serum, 2mM L-Gln, 100U/ml penicillin, 1uM sodium pyruvate, and then plated. After 48h hypotonic treatment was performed to remove germ cells as described⁴⁹, and the purity of Sertoli cell was assessed by morphology and immunofluorescent staining of WT1(purity of Sertoli cells>95%) [Fig.S2A-D,I].

RNA extraction and RT-PCR

Total RNA was isolated using TRIzol (TIANGEN,DP405) and first-strand cDNA was synthesized using a PrimeScript RT Master Mix(Takara,RR036A)for the reverse transcription (RT)-PCR. The information of primers was listed in Table S1.

ChIP-seq and ChIP-qPCR

To characterize genome-wide binding patterns of androgen receptor and WT1 in Sertoli cells, ChIP and input DNA libraries were performed as previously described⁵⁰. Briefly, cells were cross-linked with 1% formaldehyde for 10 min at room temperature and formaldehyde was then inactivated by the addition of 125 mM glycine for 5min. Sonicated DNA fragments with 100–300 bp were pre-cleared and then immunoprecipitated with Protein A+G Magnetic beads coupled with Anti-Androgen Receptor antibody (06–680, Millipore). After reverse crosslinking, immunoprecipitated DNAs and input DNAs were end-repaired and ligated adapters to the DNA fragments using NEBNext Ultra End-Repair/dA-Tailing Module (E7442, NEB) and NEBNext Ultra Ligation Module (E7445, NEB). High-throughput sequencing of the ChIP fragments was performed using Illumina NextSeq 500 following the manufacturer's protocols. The raw

sequencing data were processed with trimmomatic (version 0.36) to filter low-quality reads⁵¹. The resulting data were mapped using bowtie2 (version 2.2.9) to the UCSC mm10 genome reference⁵². Peak detection was performed using the MACS peak finding algorithm (Model-based Analysis of ChIP-Seq; version 1.4.2) with parameters --nomodel --shiftsize 25 and the p-value cutoff set to 0.05³³.

Primers for ChIP-qPCR:

GATA2-F: GCTAGAGAGTGCATTGGGGA

GATA2-R:AGTTCCTGGGGCTGCGAG

β1-integrin F:

β1-integrin R:

Control-F:TTAGGTGGCCTCAGATCCTC

Contro-R:CCTGCCTCTCTTTTGGACAG

Bicalutamide injection

Bicalutamide injection was performed as described⁵³ with minor modifications: 6-week old CD1 male mice were intraperitoneally injected with bicalutamide (20 mg/kg) or DMSO (vehicle) once every other day for 4 times.

Immunohistochemistry and immunofluorescence

Mouse testes were harvested and fixed in 4% neutral paraformaldehyde overnight, and subsequently dehydrated and embedded in paraffin. Histological sections were dewaxed and rehydrated in ethanol series, followed by microwave antigen retrieval in

0.01M citrate (pH=6.0) and methanol/H₂O₂ treatment at room temperature. After blocking with 5% goat serum, the slides were incubated with primary and biotin labeled secondary antibodies, respectively. Streptavidin-HRP (Jackson Lab, 1:500) and DAB kit (Vector, sk4100) were used for visualization. Cells immunofluorescence was carried out as described⁵⁴. See antibodies information at Table S2.

BrdU assay

Mice were intraperitoneally injected with BrdU (sigma, B5002, 50 mg/kg) 4 hours before testis harvesting. Testes were fixed in 4% neutral PFA and embedded with paraffin. For BrdU detection, sections were incubated with 2M HCl at 37 °C for 1 hour, and washed with 0.1M boric acid (pH= 8.5) for 3 times. The immunohistochemistry was performed as aforementioned (BrdU primary antibody, santa cruz, sc-32323, 1:200 dilution).

Gene silence and overexpression

The validated siRNA or shRNA sequences (table 1) were synthesized by Shanghai Genepharma company. AR expression plasmid was a gift from Prof. Zijie Sun (School of Medicine, Stanford University). *Wt1* cDNA expression plasmid (EX-Mm24822-02) and *Itgb1* cDNA plasmid (MM1013-202859073) were purchased from GeneCopoeia and Dharmacon, respectively. Plasmids or siRNA oligos were transfected using lipofectamine 3000 (Lifetechnology).

460

461

462 Western blot and Co-IP

463 For western blotting, tissue and cell lysates were separated in SDS PAGE gel and
464 transferred to nitrocellulose membrane, which was subsequently blocked with 5% skim
465 milk at 4 °C overnight and then incubated with primary antibodies at room temperature
466 for 1 h. Then the membranes were incubated with HRP-conjugated goat anti rabbit or
467 mouse IgG (santa cruz, 1:3000) and ECL, and finally exposed the film. See antibodies
468 information at Table S2. For Co-IP, lysates of adult mice testis or SSCs of 6 dpp mice
469 were prepared using a standard protocol (Beyotime,P0013), and 0.5mg total proteins

diluted by TBST were incubated with mouse anti-itgb1 antibody and rabbit anti-cdh1 antibody respectively and rocked at 4°C for overnight. The pre-washed protein (A+G) sepharose beads (Beytime,P2012) were added afterwards and incubated at 4°C for 4 hours. The beads were then washed three times with TBST, pelleted and boiled in 1XSDS loading buffer, and finally analyzed by western blot. See antibodies information at Table S2.

Statistical analysis

For cell counting, sections or immunofluorescent visual fields were selected randomly. Data were analyzed by Excel and was presented as mean \pm SD (standard deviation). Statistical significance was determined by *t*-test.

Acknowledgments

We thank Prof. Zijie Sun and Xiaodong Zhao's suggestions for AR signal study and ChIP-seq data analysis. This work was supported by the National Natural Science Foundation of China (81200472/H0425) and Fundamental Research Funds for the Central Universities in China (KYTZ201602).

Figures legends

Figure 1. Expression patterns of PLZF and AR during testis development.

PLZF staining was exclusively detected in spermatogonia localized in basal membranes
of 5 dpp (A), 10 dpp (B), 20 dpp (C) and 42 dpp (D) testes (inset in D, representative of
PLZF⁺ A_{pr} spermatogonia). AR staining in 5 dpp (E), 10 dpp (F), 20 dpp (G) and 42 dpp
(H) testes was specifically detected in Sertoli cells in the first or second layers of
seminiferous tubules. Weak AR staining was observed in pre-spermatogonia (red

arrowheads) in the testicular lumen of 2 dpp testis, but not in Sertoli cells (I). In 3 dpp testis (J), pre-spermatogonia migrated to basement membranes and formed unique structures with surrounding Sertoli cells termed niches (red arrows in J, and identical structures were also found in 4 dpp and 5 dpp testes, red arrows in E and K), and AR staining was detected in Sertoli cells but not in germ cells . K. AR staining in 4 dpp old testis, L. a representative of niche in 3 dpp testis, in which SSCs were embraced by AR⁺ Sertoli cells (red frame). AR and PLZF dual immunofluorescence exhibited AR signals and PLZF signals were not overlapped in 4 dpp testis (M. PLZF, N. AR, O. DAPI, P. merge). From neonatal to adult stages, ratio of PLZF⁺ cells in seminiferous tubules decreased (Q) but number of PLZF⁺ cells kept steady (R). Data represent means \pm SD (*p < 0.01). Bar=20 μ M.

Figure 2. Impact of androgen on SSCs differentiation in SSCs-testicular somatic cells co-culture system.

Total testicular cells isolated from testes of 5-day mice were maintained in vitro, and SSCs grew well on the layers formed by somatic cells (A). The morphology of co-culture system after two passages was exhibited (B). More A_{al} spermatogonia (red arrows) were observed in DHT treat group (C) while more clusters (red arrow heads) formed in bicalutamide treat group (D). The ratio of spermatogonia cluster/chain was calculated

after DHT or bicalutamide treatment in co-culture system (E). Expression levels of *Id4*, *Gfra1*, *Plzf*, *c-kit*, *Tex14* in SSCs-Sertoli cells co-culture system after DHT and/or bicalutamide treatment were evaluated by RT-PCR (F). Impact on expression of AR and PLZF in co-culture system caused by DHT and bicalutamide treatment was determined by western blot (G). DHT aggravated the decline of PLZF expression caused by PLZF siRNA, while bicalutamide alleviated the knockdown effect (H).

Figure 3. Screening for target genes of AR in Sertoli cells.

The representative view of AR binding sites (visualized by Integrative Genomics Viewer [<http://software.broadinstitute.org/software/igv/>]) at *Gata2* promoter region (A). ChIP-qPCR validated the binding of AR in the promoter region of *Gata2*: fold enrichment by antibodies against AR relative to control IgG was presented as mean value \pm SD of two replicates (B). Overexpression of AR or DHT treatment caused down-regulated expression levels of *Gata2*, WT1 and β 1-integrin in Sertoli cells (C). Knockdown of *Gata2* using siRNA led to decreased expressions of WT1 and β 1-integrin (D).

Figure 4. WT1 is an intermediate molecule to transmit androgen signal to downstream target β 1-integrin.

The representative view of WT1 binding sites (visualized by Integrative Genomics Viewer [<http://software.broadinstitute.org/software/igv/>]) at *β 1-integrin* promoter region

(A). ChIP-qPCR validates the binding of WT1 in the promoter region of *β1-integrin*: fold enrichment by antibodies against WT1 relative to control IgG was presented as mean value \pm SD of two replicates (B). Knockdown of WT1 in testicular somatic cells decreased $\beta1$ -integrin expression (C), and transfection of *Wt1* cDNA enhanced $\beta1$ -integrin expression (D). Androgen caused down-regulation of WT1 and $\beta1$ -integrin in co-culture system (E). Knockdown of $\beta1$ -integrin in this co-culture system led to decreased expression level of PLZF (F). An illustration hypothesizes the potential signal pathway from AR to $\beta1$ -integrin in Sertoli cells (G).

Figure 5. Identification of $\beta1$ -integrin as a putative interactive molecule between SSCs and Sertoli cells.

Thy1⁺ SSCs were co-cultured with Sertoli cells infected with control shRNA or $\beta1$ -integrin shRNA for 48 hours (A), and the expression levels of germline markers of SSCs were detected (B). RT-PCR revealed expression profiles of integrins and cadherins in SSCs at mRNA level (C). The binding of E-cadherin and $\beta1$ -integrin was detected in adult mouse testis cell lysates using immunoprecipitation, of which the binding of β -catenin and E-cadherin was used as positive control (D). Expression of $\beta1$ -integrin (E) and E-cadherin (F) in SSCs and co-cultured Sertoli cells was determined by IF. Purified Sertoli cells or Thy-1⁺ SSCs were lysed to detect the expression of $\beta1$ -integrin and E-cadherin using western blot (G). Thy-1⁺ SSCs were lysed for co-IP to detect the endogenous interaction of $\beta1$ -integrin and E-cadherin (H).

Figure 6. Bicalutamide recipient mice lack of spermatocytes and spermatids, but possess hyper-proliferative SSCs.

Bicalutamide recipient mice (n=33) exhibited retarded body weight growth (A) and smaller testis size (B). Histology demonstrated significantly reduced spermatocytes and spermatids in seminiferous tubules of bicalutamide recipients (E) compared with those of control (F). IHC staining displayed reduced number of AR⁺ cells (G) and increased number of PLZF⁺ cells (I) in bicalutamide recipients than in controls (H and J). A statistical result indicated a augmented population of PLZF⁺ cells (C) and a remarkable decline of AR⁺ cell population (D) in seminiferous tubules of bicalutamide recipients, data represent means \pm SD (*p < 0.01). Accumulated spermatogonia formed two layers in bicalutamide recipient seminiferous tubules (green frame in K), while wild type seminiferous tubule possessed only one layer of spermatogonia (green frame in L). Most of the spermatogonia in those two layers were β 1-integrin⁺ (N), c-kit⁺ (O) PLZF⁺ (M). BrdU assay indicated they were mitosis active (P), as those in wild type (Q). Spermatogonia layers were enclosed by red frames in M, N, O, P and Q. Bicalutamide recipient testes displayed down-regulated expression of *Ar*, *Sycp3*, *Claudin-11*, *WT1*, *Nectin-2*, and up-regulated expression of *Plzf*, *Gata2*, *Wt1* and *β 1-integrin* (R).

Figure 7. The hypothesis of putative regulation mechanism of spermatogenesis induced by androgen.

Androgen deprivation may block spermatogenesis at the step that β 1-integrin⁺c-kit⁺

population transits to more differentiated germ cells, causing accumulation of undifferentiated spermatogonia (A). Androgen produced by Leydig cells interacts with AR in Sertoli cells to regulate down-stream target genes, and subsequently transfer differentiation signals to SSCs, and finally turns off the differentiation inhibitor gene *Plzf* via multiple steps. *Gata2* was identified as a target gene of AR, and *Wt1* was activated by *Gata2* to regulate downstream gene $\beta 1$ -*integrin* in Sertoli cells. How $\beta 1$ -integrin on Sertoli cells influences SSCs' fates by regulation of *Plzf* expression is unknown (B).

Figure S1. SSCs-somatic cells co-culture system was able to be maintained in vitro for short term.

SSCs-somatic cells co-culture system stably expressed MVH (A. bright filed, B. MVH, C. dapi, D. merge), PLZF (E. bright filed, F. PLZF, G. dapi, H. merge), WT1 (I. bright filed, J. WT1, K. dapi, L. merge), AR (M. bright filed, N. AR, O. dapi, P. merge) and CD9 (Q. bright filed, R. WT1, S. dapi, T. merge). RT-PCR results exhibit the co-culture system expresses somatic markers (U. 1.*Gapdh*, 2.*Sox9*, 3. *Sma*, 4.*Coopu-tf*, 5. *Wt1*, 6.*Mvh*), and *Ar* (V.1) *Ar*, and germline markers (V. 2.*Scp3*, 3.*ckit*, 4.*integrin-aV*, 5.*Cd9*, 6.*integrin-1*, 7.*Plzf*, 8. *Mvh*) after 3 passages. Western blot result confirmed this co-culture system was sensitive to DHT or bicalutamide stimulation (W).

Figure S2. Purified Sertoli cells were used for ChIP-seq analysis and co-culture.

Bright field (A), WT1 staining (B), DAPI (C) and merge (D) of purified Sertoli cells. WT1⁺

ratio of purified Sertoli cells was higher than 95% (I). Purified Sertoli cells were examined for β 1-integrin expression by IF (E-H), and then were infected with β 1-integrin shRNA lentivirus to interfere in endogenous expression of β 1-integrin before co-culture with SSCs. Morphology of Sertoli cells 96 hours post infection (J), and infection efficiency was examined by expression of reporter gene RFP (red fluorescence protein) (K). Western blot revealed relative expression level of β 1-integrin was approximately decreased by 80% after β 1-integrin shRNA interfering (L).
