## 23 **Abstract**

24       Density and nutrient level are important factors that might affect the growth of invasive  
25 plants. To reveal the effects of plant density on the performance of invasive plant *Alternanthera*  
26 *philoxeroides* under different nutrient conditions, a greenhouse experiment was conducted in  
27 which *A. philoxeroides* was planted at three densities (low, medium and high) under three  
28 nutrient levels (low, medium and high). The results showed that both planting density and  
29 nutrient levels had significant effects on the growth of the plant. The biomass of individual plant  
30 and all plants in one pot under medium nutrient level were the highest while the photosynthetic  
31 rate and total chlorophyll content were the highest at the high nutrient level. Under different  
32 nutrient levels, the photosynthetic rate was the highest at medium planting density. The biomass  
33 of single plant decreased with the increase of population density, while the total biomass in the  
34 whole pot increased with the increase of density. These characteristics might contribute to the  
35 invasion of *A. philoxeroides* and help the plant to form monodominant community.

## 45 Introduction

46 Biological invasion has far reaching impacts on ecological functions and the ecological  
47 diversity of native environments [1-5]. The invasive species have high fecundity, and once the  
48 invasion succeeds, it is easy to form the predominant population. The success of biological  
49 invasion is not only determined by the physiological and genetic characteristics of invasive  
50 species, but also by the factors such as population density and nutrient levels [6-10].

51 The nutrient is one of the important factors for plant growth. Previous studies have found  
52 that traits associated with the resource used determine the invasion success of several invasive  
53 species [11, 12]. Invasive plants generally show stronger photosynthesis and growth when  
54 invading habitats with richer nutrients [12-15]. Therefore, the nutrient level is also associated  
55 with the invasion success [9]. The research on the influence of nutrient on invasive plants plays  
56 an important role in understanding the successful plant invasion.

57 The competition among plants is also an important factor affecting the spatial distribution,  
58 dynamics and species diversity, promoting the succession of communities [16]. Invasive plants  
59 can replace local plants through interspecific competition, accomplishing the process of  
60 successful invasion [17]. However, when invasive plants spread to a certain extent, there is a  
61 degree of intraspecific competition. In order to adapt to this change, plants tend to change their  
62 own characteristics, such as plant height, biomass of branches and physiological characteristics  
63 of leaves, etc [18, 19]. And this phenotypic plasticity allows invaders to allocate more nutrients  
64 than their native counterparts to increase biomass [20, 21]. Several studies found that the  
65 physiological indexes of invasive plant under high density are less than those under low  
66 population density [8, 22]. Plant density determines the competitiveness of aquatic clonal plants

67 in complex habitats [23]. Therefore, we can analyze the growth mechanism by studying the  
68 morphological changes of plant. At the same time, the effect of population density on invasive  
69 plants is one of the core problems in the study of invasion ecology at present [24].

70 Aquatic species might have a fast response to nutrient enrichment, increasing their biomass  
71 rapidly, which is particularly true in the aquatic invasive species [9, 25-27]. Therefore, aquatic  
72 invasive species affects the productivity and management of land and water resources  
73 worldwide [28]. *A. philoxeroides* is one of these aquatic invasive plants. It is a clone weed that is  
74 native to South America and it is a stoloniferous and rhizomatous perennial herbaceous plant  
75 [28-30], which propagates clonally and expands rapidly in both aquatic and terrestrial habitats  
76 [31-34]. *A. philoxeroides* has experienced an invasion history of more than 80 years in China and  
77 become one of the most harmful invasive species [34]. At present, there are many researches  
78 focused on the physiological characteristics of *A. philoxeroides*, its response to natural  
79 environmental factors, and biological and chemical control [10, 35-37]. Many studies have shown  
80 that if the plant has a high photosynthetic rate, and it usually grows and propagate rapidly [38,  
81 39]. Moreover, the invasive capacity of invasive plants is closely related to the ability of  
82 photosynthesis, they often enhance its invasive ability by increasing the photosynthesis of  
83 ramets [40, 41]. Thus, studying the photosynthetic capacity of *A. philoxeroides* is essential for  
84 understanding the potential of invasive species and to develop appropriate control strategies.

85 Our previous studies have compared the growth of *A. philoxeroides* with native plants [10].  
86 So in the present study, we conducted a greenhouse experiment which combined nutrient levels  
87 with planting density to explore their effects on the growth and photosynthetic characteristic of  
88 *A. philoxeroides*. We asked the following questions: (1) Will the increase of planting density

89 inhibit the growth of *A. philoxeroides* under various nutrient levels? (2) How do the nutrient level  
90 and planting density affect the invasion of *A. philoxeroides*.

91

## 92 **Materials and methods**

### 93 **Ethics statement**

94 We collected plant material for our study with the official permission of the Environmental  
95 Protection Bureau of Weishan County, and the Management Committee of the Weishan Lake  
96 Constructed Wetland Park. We did not collect endangered or protected species.

97

### 98 **Plant material and experimental design**

99 The *A. philoxeroides* seedlings were collected from Weishan Lake Wetland Park, Shandong  
100 province, in July 2017. The seedlings were cultured a week in the greenhouse of Fanggan  
101 Research Station of Shandong University (36°26'N, 117°27'E). The method of sand culture was  
102 used in the experiment, and the river sand was washed thoroughly before planting. The length of  
103 the selected stem was about 11cm, and then was transplanted into a pot (h: 23.5cm; d: 22cm)  
104 with 7 kg sand. Set up two factors in our experiment: the nutrient level of the sand and planting  
105 density of *A. philoxeroides*. The nutrient treatments consisted of three levels (low, medium and  
106 high; labeled as A, B and C) and three kinds of planting density (low, medium and high; 1, 2 and 4  
107 seedlings per pot, respectively). In total, there were nine treatment combinations, each dealing  
108 with five replicates. The nutrient levels and planting density settings in the experiment are  
109 shown in Table 1.

110 **Table 1. Nutrient levels and planting density of *A. philoxeroides* at different treatment.**

| Nutrient levels | TN<br>(g kg <sup>-1</sup> sand) | Amount of chemical<br>fertilizer added<br>(g kg <sup>-1</sup> sand) | planting density | planting number<br>(plant pot <sup>-1</sup> ) |
|-----------------|---------------------------------|---|------------------|---|
| A               | 0.5                             | 2.5   | 1                | 1   |
|                 |                                 |   | 2                | 2   |
|                 |                                 |   | 4                | 4   |
| B               | 0.7                             | 3.5   | 1                | 1   |
|                 |                                 |   | 2                | 2   |
|                 |                                 |   | 4                | 4   |
| C               | 2.1                             | 10.5  | 1                | 1   |
|                 |                                 |   | 2                | 2   |
|                 |                                 |   | 4                | 4   |

111 \*A, B, and C: low, medium and high nutrient levels.

112 In the experiment, the compound fertilizer with the ratio of nitrogen and phosphorus (N: P  
113 = 4: 1) similar to Nansi Lake was used as the nutrient source. According to our previous  
114 experiments, the medium nutrient gradient in this experiment is the most suitable for the  
115 growth of *A. philoxeroides* [37]. Water 200 mL every day, in order to ensure the normal growth  
116 of *A. philoxeroides*, and would not lead to the loss of fertilizers in the pot. At the time of  
117 fertilization, grounding the fertilizer into powder, then half dissolved in 200 mL of water each  
118 time, added for two days, to prevent once adding cause damage to plants. At the time of  
119 experiment, the low nutrient level was added the fertilizer only in the first week; medium and  
120 high nutrient levels were added every two weeks during the experiment. The time of the

121 experiment was from the July 24, 2017 to September 20, 2017.

122

## 123 **Determination of photosynthetic rate and light response**

### 124 **curve**

125 The photosynthetic characteristics of each group were measured by a Portable  
126 Photosynthesis System (*LI-COR 6800*, USA) using PAR of 1000  $\mu\text{molm}^{-2}\text{s}^{-1}$ . Leaves were measured  
127 under ambient  $\text{CO}_2$  concentration [ $385 \mu\text{molmol}^{-1}$ ] [42]. The light response curves were  
128 measured under the PAR of 1600, 1200, 1000, 800, 600, 400, 200, 100, and 0  $\mu\text{molm}^{-2}\text{s}^{-1}$  [42].  
129 The fitting of the light response curve adopts a non - right - angle hyperbolic model, and the  
130 model formula is:

$$131 \quad Pn = \frac{\alpha I + Pn_{\max} - \sqrt{(\alpha I + Pn_{\max})^2 - 4\theta\alpha I Pn_{\max}}}{2\theta} - Rd$$

132 In this formula,  $\alpha$  is the apparent quantum rate;  $I$  is the light quantum flux density;  $Pn_{\max}$   
133 is the maximum photosynthetic rate;  $Rd$  is the dark respiration rate;  $\theta$  is the angle parameter  
134 that reflects the degree of bending of the light response curve, and the range of values is  $0 \leq$   
135  $\theta \leq 1$  [43]. According to the light response curve, we calculated the light compensation point  
136 (LCP) and the light saturation point (LSP).

137

## 138 **Determination of chlorophyll content**

139 In each treatment, using a volume fraction of 95% ethanol extract chlorophyll, then the  
140 spectrophotometer was used to measure the absorbance values at 649nm and 665nm  
141 wavelength [44]. The concentration of chlorophyll a, chlorophyll b and total chlorophyll were  
142 calculated according to the formula:

$$Ca = 13.95A_{665} - 6.88A_{649}$$

$$Cb = 24.96A_{649} - 7.32A_{665}$$

143  $Cr = Ca + Cb = 18.08A_{649} - 6.63A_{665}$

144 In the formula, Ca, Cb and Cr represent the concentrations of chlorophyll a, chlorophyll b and  
145 total chlorophyll respectively, [mg cm<sup>-2</sup>]; A<sub>649</sub> and A<sub>665</sub> represent the absorbance at the  
146 wavelengths of 649 nm and 665 nm respectively [45].

147

### 148 **Determination of specific leaf area (SLA) of *A. philoxeroides***

149 Before harvest, randomly selected 20 mature leaves of each treatment, wiped clean and  
150 flattened on the scanner. The determination of leaf area using Photoshop software.

151 Leaf area = the percentage of leaf pixels / background pixels · background paper area [46-48].

152 SLA = leaf area / leaf dry weight.

153

### 154 **Determination of morphological indexes of *A. philoxeroides***

155 We measured the length of stolon and recorded the number of internode before harvest.

156 The internode length of *A. philoxeroides* under different treatments was calculated.

157

### 158 **Determination of biomass index of *A. philoxeroides***

159 At the end of the experiment, the roots of *A. philoxeroides* were washed thoroughly, and

160 the leaves, stems and roots of each treatment were respectively put into the envelopes,

161 numbered and then dried up to constant weight in an oven which the temperature was 80 °C,

162 recorded the dry weight of each part.

163

## 164 Statistical analysis

165 The date of different variables, such as biomass, photosynthetic rate, SLA and total  
166 chlorophyll content was analyzed by two-way ANOVA with SPSS 21.0 software (Table 2). The  
167 significance test in all tests was performed at a level of  $P < 0.05$ . Use Origin 8.5 software to draw  
168 charts.

## 169 Results

170 **Table 2. The two-way ANOVA of the effects of the independent variable nutrient level and**  
171 **plant density, and their combination on studied parameters of species *A. philoxeroides* in**  
172 **the experiment.**

173

## 174 **Effects of density on Plant Biomass Index and Morphology**

### 175 **Index under different nutrient gradients**

176 Results showed that the interaction between nutrient level and plant density significantly  
 177 affect the leaf biomass of per plant, single plant biomass, total leaf biomass and total biomass of  
 178 a whole pot (Table 2).

179 Under three nutrient levels, the leaf biomass of single plant and the biomass of single plant all  
 180 decreased significantly with the increase of planting density (Table 3). Among various nutrient  
 181 levels, under three planting density, the reduction rate of leaf dry weight per plant was 47.9%,  
 182 53.9%, 62.5%; the reduction rate of biomass per plant was 57.2%, 64.4%, 63.4% (Table 3). At

183 different nutrient levels, the difference in the leaf biomass of per plant between low density (1)  
184 and medium density (2) was slightly greater than the difference between medium density (2) and  
185 high density (4) (Table 3). At every nutrient levels, there was a significant difference in the  
186 biomass of single plant among all three planting densities (Table 3). In low nutrient level (A), the  
187 difference between medium planting density (2) and high planting density (4) is slightly larger  
188 than that between low planting density (1) and medium planting density (2) (Table 3). Under  
189 medium nutrient (B) and high nutrient (C), the gap between low density (1) and medium planting  
190 density (2) is slightly larger than medium planting density (2) and high planting density (4) (Table  
191 3).

192 At the three nutrient levels, the total leaf biomass and the total biomass of a pot all  
193 increased significantly with the increase of planting density (Table 3). To total leaf biomass of *A.*  
194 *philoxeroides*, there was no significant difference between low planting density (1) and medium  
195 planting density (2) under the treatment of low (A) and medium (B) nutrient levels and the  
196 difference among the three planting densities was not significant under the high nutrient level (C)  
197 treatment (Table 3). For total biomass of a pot, at low nutrient level (A), the difference between  
198 medium planting density (2) and high planting density (3) is significantly smaller than that  
199 between low planting density (1) and medium planting density (2), besides there is no significant  
200 difference between low planting density (1) and medium planting density (2) at medium (B) and  
201 high (C) nutrient levels (Table 3).

202 According to the two-way ANOVA analysis (Table 2), there were have obvious interaction  
203 between nutrient level and plant density on internode length of *A. philoxeroides*.

204 With the increase of planting density, the average internode length of *A. philoxeroides*

205 decreased in varying degrees, and the internode length was the longest at the treatment of low  
 206 planting density (1) (Table 3). At the treatment of three nutrient levels, the average internode  
 207 length of medium nutrient level (B) was the highest, is 5.6 cm (Table 3).

208 **Table 3. Different nutrient levels and different planting densities of *A. philoxeroides* biomass**  
 209 **and morphological index.**

| Treatments | Single leaf<br>biomass<br>(g) | Total leaf biomass<br>(g) | Single biomass<br>(g) | Total biomass<br>(g) | Internode length<br>(cm) |
|------------|-------------------------------|---------------------------|-----------------------|----------------------|--------------------------|
| A1         | 2.90±0.56d                    | 2.90±0.56e                | 22.83±3.35b           | 22.83±3.35d          | 5.66±0.28ab              |

210 \*A, B, and C: low, medium and high nutrient levels; 1, 2, and 4: the number of seedlings per pot.

211 Values are presented as means ±SD. Different letters indicate significant differences (p<0.05)

212

213 **Effects of plant density on SLA of *A. philoxeroides* under**  
 214 **different nutrient levels**

215 According to the two-way ANOVA analysis (Table 2), there is no interaction between effects of  
216 nutrient level and plant density on SLA of *A. philoxeroides*.

217 The SLA of *A. philoxeroides* increased significantly with the increase of nutrient level (Fig 1).

218 Different planting density had certain effects on the SLA of *A. philoxeroides*, which was the  
219 highest under medium planting density (2) and the lowest under high planting density (4), and  
220 both have significant differences (Fig 1).

221 **Fig 1. The SLA of *A. philoxeroides* at different nutrient level and plant density.** A, B, and  
222 C: low, medium and high nutrient levels; 1, 2, and 4: the seedlings per pot. Values are  
223 presented as means  $\pm$ SD. Different letters indicate significant differences ( $p < 0.05$ ).

224

## 225 **Effects of density on photosynthetic rate and total chlorophyll** 226 **content of *A. philoxeroides* under different nutrient levels.**

227 We found that nutrient levels and planting densities on the photosynthetic rate of *A.*  
228 *philoxeroides* has a obvious interaction, and for the total chlorophyll content, they had no  
229 significant interaction to it (Table 2).

230 The analysis of photosynthetic rate and total chlorophyll content of *A. philoxeroides* under  
231 different treatments showed that the change trend of the two indexes are basically the same,  
232 and both of them increased with the increasing nutrient level (Fig 2). The photosynthetic rate of  
233 medium planting density (2) of the three nutrient levels were the highest and had significant  
234 differences, and they were the lowest under the treatment of high density (3) (Fig 2-A). The total  
235 chlorophyll content of the medium nutrient (B) and high nutrient (C) had obvious differences (Fig  
236 2-B). The total chlorophyll content of *A. philoxeroides* reached the maximum under high nutrient

237 level (C), and for the planting density, when the planting density was medium (2), the total

238 chlorophyll content of *A. philoxeroides* reached the maximum (Fig 2-B).

239 **Fig 2. The photosynthetic rate and chlorophyll content of *A. philoxeroides* at different**  
240 **nutrient levels and plant densities.** A, B, and C: low, medium and high nutrient levels; 1, 2,  
241 and 4: the number of seedlings per pot. Values are presented as means  $\pm$ SD. Different letters  
242 indicate significant differences ( $p < 0.05$ ).

243

## 244 **Effects of density on light response curve of *A. philoxeroides*** 245 **under different nutrient levels.**

246 The data were analyzed and fitted by SPSS software. The fitting coefficients ( $R^2$ ) of the light  
247 response curve of each group were all greater than 0.9, which showed that the curve fitting  
248 degree was better and the photosynthetic characteristic of *A. philoxeroides* could be more  
249 accurately reflected.

250 With the increase of the nutrient level, the maximum photosynthetic rate ( $Pn_{max}$ ) of *A.*  
251 *philoxeroides* increased in different degrees, so the  $Pn_{max}$  at the high nutrient level (C) were the  
252 largest (Table 4). Among different planting density the  $Pn_{max}$  of *A. philoxeroides* were the largest  
253 at the treatments of medium planting density (2), and the  $Pn_{max}$  of *A. philoxeroides* was minimal  
254 under the high planting density (4) (Table 4). Besides, under the same nutrient level treatment,  
255 there were significant differences among the three different planting densities on the  $Pn_{max}$  of *A.*  
256 *philoxeroides* (Table 4).

257 The light compensation point (LCP) and light saturation point (LSP) of *A. philoxeroides* under  
258 different nutrient treatments were the biggest when planting density was medium (2), and when  
259 the planting density was high level (4), the value of LCP and LSP were the smallest (Table 4). At  
260 the same planting density, both LCP and LSP increased with increasing nutrient levels, among  
261 them, there was a larger gap between medium nutrient (B) and high nutrient (C) (Table 4). Under

262 the same nutrient level, at the difference of the value of LCP and LSP between medium planting  
263 density (2) and high planting density (4) was larger than that between medium planting density  
264 (2) and low planting density (1) (Table 4).

265 **Table 4. Light response curve parameters of *A. philoxeroides* at different nutrient levels and**  
266 **planting densities.**

| Treatments | Pn <sub>max</sub> | LCP            | LSP              |
|------------|-------------------|----------------|------------------|
| A1         | 4.79 ± 0.30g      | 51.54 ± 4.60fg | 250.21 ± 14.90e  |
| A2         | 6.08 ± 0.28f      | 56.39 ± 4.46f  | 283.08 ± 9.79d   |
| A4         | 3.77 ± 0.25h      | 40.68 ± 3.92h  | 205.30 ± 16.82f  |
| B1         | 7.55 ± 0.34e      | 65.48 ± 3.67e  | 307.15 ± 8.56c   |

| C4         | 10.00 ± 0.82c     | 84.09 ± 4.33c  | 355.47 ± 21.62b  |

267 \*A, B, and C: low, medium and high nutrient levels; 1, 2, and 4: the number of seedlings per  
268 pot. Values are presented as means ±SD. Different letters indicate significant differences (p<0.05)

269

## 270 Discussion

271 In our experiment, nutrient and planting density had significant interaction effects on the  
272 biomass accumulation of *A. philoxeroides*. Under the same planting density, the biomass  
273 accumulation of *A. philoxeroides* could be promoted by increasing nutrients [49-51]. And our

274 previous studies concluded that compared with native plants, the *A. philoxeroides* had better  
275 environmental adaptability and higher biomass and ratio of leaf area under different nutrient  
276 conditions [10, 37]. At the treatment of medium nutrient level, the whole pot biomass of *A.*  
277 *philoxeroides* among three different planting densities was the highest, indicating that too high  
278 nutrient levels could be harmful for *A. philoxeroides* at the initial stage. At medium nutrient level,  
279 the increase of planting density had the most obvious effects on the single plant biomass of *A.*  
280 *philoxeroides* and the effects will be weakened at low nutrient. Therefore, we conclude that  
281 under appropriate nutrient level, the effects of planting density on the growth of *A. philoxeroides*  
282 were nutrient dependent. Some studies have shown that at same nutrient condition, the  
283 biomass of invasive plants increased more than that of native plants [52]. So in our experiments,  
284 under the same nutrient level, although the biomass of single plant was reduced with the  
285 increase of planting density, the total biomass of the plant in whole pot was increased, especially  
286 at low nutrient. That would enhance the invasive ability of *A. philoxeroides*.

287 In addition, according to the leaf biomass of *A. philoxeroides*, we analyzed the SLA of *A.*  
288 *philoxeroides*. In our study, with the increase of nutrient level, the SLA of *A. philoxeroides*  
289 increased, which is consistent with the studies on SLA of other plants [53-55]. Similarly, the  
290 increase of planting density has different influences on the SLA of *A. philoxeroides*. In this study,  
291 the SLA of *A. philoxeroides* was the highest under medium planting density treatment. SLA is one  
292 of the important plant leaf traits and closely related to plant growth and survival strategy. Its  
293 value can reflect the ability of plant leaves to intercept light and self-protection in bright light  
294 [56]. It is closely related to the photosynthesis and respiration of plants [57]. We therefore  
295 concluded that at the medium planting density, the leaf of *A. philoxeroides* had a higher net

296 photosynthetic rate. So we then analyzed the photosynthetic rate of rate of each treatments to  
297 confirm our conclusion.

298 In this study, photosynthetic rate had increase with the increasing nutrient levels that is  
299 consistent with previous studies [58-60]. Among the three kinds of plant density treatment, the  
300 photosynthetic rate in medium planting density was the highest, and the difference with high  
301 planting density was obvious. Chlorophyll is the main pigment of photosynthesis in plants, which  
302 reflects the size of photosynthesis in plants [44]. By this experiment, we found that the content  
303 of the total chlorophyll of *A. philoxeroides* had the same trend, indicating that under medium  
304 planting density, plants can capture resources better [61].

305 In order to better understand the effects of planting density on the photosynthetic  
306 characteristics of *A. philoxeroides* under different nutrient conditions, we studied the light  
307 response curve parameters of *A. philoxeroides*. Photosynthetic parameters, such as maximum  
308 photosynthetic rate ( $Pn_{max}$ ), light compensation point (LCP) and light saturation point (LSP), are  
309 important scientific basis for rapid growth of plants [62-64]. Light saturation point (LSP) can  
310 reflected the adaptability of plants to strong light; the lower the light compensation point (LCP) is,  
311 the better the normal photosynthesis is under the weak light and the maximum net  
312 photosynthetic rate ( $Pn_{max}$ ) reflects the utilization ability of *A. philoxeroides* to strong light under  
313 different treatments. In our study, among the three kinds of nutrient, the  $Pn_{max}$ , LCP and LSP of  
314 the *A. philoxeroides* seedlings in medium planting density were the largest, indicating that under  
315 this treatment, *A. philoxeroides* had the strongest utilization ability and adaptability to glare, and  
316 under high planting density, *A. philoxeroides* has better capability to utilize weak light. Moreover,  
317 the photosynthetic parameters of the plant increased with the increasing nutrient levels. That is

318 similar to previous studies [65, 66]. It shows that the increase of nutrient will enhance the  
319 utilization ability of *A. philoxeroides* to strong light. This suggests that at higher nutrient levels,  
320 higher light intensities are required to produce more biomass, may be that is why the *A.*  
321 *philoxeroides* has higher photosynthetic rate but the biomass is lower than the medium nutrient  
322 level. Under the same nutrient level, the increase of planting density resulted in the decrease of  
323  $Pn_{max}$ , LCP and LSP and there were significant differences among the three planting densities. The  
324 results suggested that the increase of planting density decreased the  $Pn_{max}$  of *A. philoxeroides*  
325 and its ability to use strong light and its adaptability. Under the low nutrient level, there was no  
326 obvious difference in the LCP between the medium and low planting density, which indicated  
327 that under the low nutrient level, the high planting density *A. philoxeroides* had more obvious  
328 photosynthetic ability at low light. But at the medium and high nutrient levels, the planting  
329 density had more obvious influence on the LCP of *A. philoxeroides*, and the effects became more  
330 obvious with the increase of nutrient level.

331 In conclusion, our study showed that at the three nutrient levels, the SLA, photosynthetic  
332 rate and total chlorophyll content of *A. philoxeroides* at medium planting density were the  
333 highest. What's more, although the biomass of single plant, SLA, photosynthetic rate and the  
334 content of Chlorophyll reduced with the increase of planting density, the biomass of whole pot  
335 tended to increase. These attributes may increase the competitive dominance of *A. philoxeroides*  
336 and could help the *A. philoxeroides* population develop into a monodominant community.
