Teachers' choice of content and consideration of controversial and sensitive

issues in teaching of secondary school genetics

Abstract

Science education strives to increase interest in science and facilitate active citizenship. Thus,

the aspects of personal and societal relevance are increasingly emphasised in science

curricula. Still, little is known about how teachers choose content for their teaching, although

their choices translate curricula to teaching practice. We explored how teachers choose

genetics content and contexts for biology courses on cells, heredity and biotechnology by

interviewing ten Finnish upper-secondary school teachers. We specifically studied how the

teachers described teaching on genetically modified organisms, hereditary disorders, and

complex human traits as teachers have different amounts of freedom afforded by curricula in

choosing contents and contexts on these themes. We analysed interviews with theory-guiding

content analysis and found consistent patterns in teachers' perceptions of the main themes in

genetics teaching, teacher inclinations towards teaching genetics in human context and

perceptions of students' interest in different topics. These patterns, which we call emphasis of

content in genetics teaching could be classified to *Developmental*, *Structural* and *Hereditary*.

Teachers with *Developmental* emphasis embraced teaching genetics in a human context,

while teachers with a *Structural* emphasis avoided them. In general, teachers justified their

choices by national, local school, and personal factors. While teachers mentioned that societal

and personal contexts are important, at the same time teachers never framed the main themes

in genetics with these contexts. We conclude that how teachers handle issues of societal or

personal relevance should be emphasized.

Keywords: *genetics content, curriculum, biology education, socio-scientific issues*

Introduction

Curriculum articulates learning goals in school and guides teaching. In Finland, the national

curricular goals are managed by legislation: the municipal authorities have an autonomy to

provide and organise education at the local level and teachers are valued as experts who are

able to develop and implement the school-specific curriculum (Niemi, Toom, & Kallioniemi,

2012). Thus, the curriculum allows teachers a remarkable responsibility and freedom to

implement education in emphasizing the contents of upper-secondary school courses (Finnish

National Board of Education, FNBE, 2003; Niemi et al., 2012). While curricular development

and its effectiveness have been studied extensively (e.g., Hargreaves, Lieberman, Fullan, &

Hopkins, 2010; Niemi et al., 2012), there has been less research produced on how teachers

choose course content for their teaching.

To substantial extent, teacher beliefs guide how teachers value different aspects of knowledge

and how much they emphasise different content (Cheung & Wong, 2010; Cronin-Jones, 1991;

Haney, Czerniak, & Lumpe, 1996). Teachers' 'personal knowledge' is not static, but is

formed through everyday experiences and formal schooling, including teacher education; it is

further moudled in continuing professional education (Gess-Newsome & Lederman, 1995;

Henze, Van Driel, & Verloop, 2007; Van Driel, Beijaard, & Verloop, 2001). Thus, this

personal knowledge shapes teaching to a large extent (Hashweh, 1987, 2005; van Driel, Bulte,

& Verloop, 2008). Nevertheless, personal knowledge often manifests through rules-of-thumb,

rather than formal design (Wieringa, Janssen, & van Driel, 2011). Consequently, curricular

change can cause truly little change in teaching approaches if underlying beliefs about content

and the best suited methods to teach content do not change in teachers' practice (Cohen &

Yarden, 2009; Tidemand & Nielsen, 2017).

The main tools for content selection are the available teaching materials, especially textbooks

(Remillard & Bryans, 2004; Shawer, 2017; Spiegel & Wright, 1984). Teachers have a conflict

between following the textbooks' content and using them critically, as teachers seem to

understand critical reading of texts as distancing themselves from the text (Loewenberg Ball,

Feiman-Nemser, Ball, & Feiman-Nemser, 1988).

Controversial and sensitive issues in teaching

According to the definition used by Oulton, Dillon, and Grace (2004), we define controversial

issues as issues on which groups within society hold differing views based on different sets of

information or different interpretations from the available information due to their worldview,

such as different value systems. Sometimes controversial issues may be resolved by acquiring

additional information, but not always. For sensitive issues, we follow the ideas of Rowling

(1996), who suggests that the distinction between sensitive and controversial issues seem to

be that sensitive issues are connected to emotionality and the involvement of the individual.

Sensitivity can arise from political, religious, cultural, personal or gender sources, but in

comparison to controversial issues, which by definition usually work on a societal level,

sensitive issues are more personal.

Real world applications of science commonly involve controversial issues; however, teachers

are generally poorly prepared for teaching controversial issues (Oulton, Dillon, & Grace,

2004; Oulton, Day, Dillon, & Grace, 2004). Furthermore, less experienced teachers do not

seem to select topics that could be upsetting to students (Hess, 2008; Phillips, 1997).

Controversial and sensitive issues may appear when teaching different contents of biology,

especially in the framework of socio-scientific issues (Lederman, Antink, & Bartos, 2014;

Lewis & Leach, 2006; Zeidler, Walker, Ackett, & Simmons, 2002). Nevertheless, it is known

that some teachers are unwilling to use this framework in their teaching (Lazarowitz & Bloch,

2005; Lee, Abd-El-Khalick, & Choi, 2006). Several reasons have been proposed to explain

this phenomenon, including limitations of the curriculum or assessment techniques, teachers'

pedagogical competence and their lack of support for the merits of SSI discussions as

pertinent to specific subjects (Bryce & Gray, 2004; Gray & Bryce, 2006; Lewis & Leach,

2006; Newton, Driver, & Osborne, 1999).

Arguably teacher beliefs are important factors that affect whether teachers embark on

discussions of controversial issues (Cotton, 2006). Most of the research on teaching

controversial issues has largely been in history and social science classes (i.e., Hess, 2008;

Oulton et al., 2004a; Oulton et al., 2004b) while sensitive issues are discussed in health and

physical education (Lynagh, Gilligan, & Handley, 2010; Rowling, 1996). Science subjects

have been less studied, even though they do not lack controversial or sensitive topics

(Leonard, 2010; Levin & Lindbeck, 1979; Owens, Sadler, & Zeidler, 2017). In discussing

controversial issues, teachers have mentioned problems in beginning and maintaining

discussions, dealing with students' "lack of knowledge", insufficient teaching time, and

scarcity of resources (Dawson & Venville, 2008; Dawson & Taylor, 2000; Hand & Levinson,

2012; Kuş, 2015; Reiss, 1999). One of the solutions should be finding ways to increase

teachers' confidence to implement teaching societally relevant issues, even though they could

be controversial (Hofstein, Eilks, & Bybee, 2011).

Teachers' beliefs seem to relate to their teaching in several ways. For example, their own

understanding whether they are experts in biology versus experts in discussing human

genetics seems to be one of the central problems (Pedretti, Bencze, Hewitt, Romkey, & Jivraj,

2008; Tidemand & Nielsen, 2017). Teachers' content and context choice also have been

found to affect also students' learning: for example, in a Swedish study, upper-secondary

school students majoring in science used few justifications from ethics or morality when

discussing GMOs (Christenson, Chang Rundgren, & Zeidler, 2014).

Genetics content and curricular development

Genetics in the secondary school biology curriculum has been emphasised in recent years, as

the progress in both basic science of genetics and its technological applications has been

rapid. This is likely to lead to both curricular renewal and the requirement for continued

teacher development. Choosing content for genetics courses is challenging for teachers and

that difficult process illustrates a teacher's perspective on teaching genetics.

There have been a few endeavours to outline the core (conceptual) contents of genetics on

different levels of lower and upper secondary school curricula. Stewart, Cartier and Passmore

(2005) outlined that a basic understanding of genetics requires understanding three basic

models: genetic (i.e., Mendelian inheritance patterns), meiotic (i.e., chromosome segregation

and assortment) and biomolecular (i.e., the genotype-to-phenotype process). This was in turn

refined by Duncan et al. (2009) who added environment as a context and outlined their

learning progression around two big ideas: 1) "All organisms have genetic information that is

universal and specifies the molecules that carry out the functions of life. While all cells have

the same information, cells can regulate which information is used (expressed)." and 2)

"There are patterns of gene transfer across generations. Cellular and molecular mechanisms

drive these patterns and result in genetic variation. The environment interacts with our genetic

makeup leading to variation." Furthermore, in their Delphi study of genetic literacy,

Boerwinkel et al. (2017) added a difference between somatic and germ line and polygenic

inheritance to previous core contents and also emphasised also sociocultural and epistemic

knowledge. In general, the diversification of core contents in genetics education from

Mendelian genetics to polygenic traits seems to mirror the change in gene research emphasis

from quantitative genetics to genomics and whole-genome sequencing. Combining the

insights of all this research could help teachers gain more confidence in choosing content for

genetics courses.

Genetics in the Finnish upper-secondary school biology curriculum

In Finland, approximately half of each age class enter general upper secondary schools, which

aims to both provide general knowledge required for an active participation in society and

prepare students for further education on the tertiary level and working life. Finnish biology

teachers at upper secondary level have at least a Masters level degree, including one-year of

studies in teacher education and one year of biology study (see Niemi et al., 2012).

Finnish curricula tend to leave substantial freedom for teachers to interpret the educational

aims and develop multiple methods to implement curricula. Finnish teachers plan teaching

according to local curricula, which are formulated by the education providers and schools

based on the national core curriculum for general upper-secondary schools (FNBE, 2003) The

core content pertaining to genetics is primarily limited to two courses: Cells and heredity

(BI2), which is mandatory for all students and Biotechnology (BI5), which is an optional

course in the biology curriculum (Table 1).

[Table 1 here]

While teachers' practices and attitudes towards different teaching approaches and methods

have been widely studied in science education (e.g., Lederman & Abell, 2014), there is far

less research on what contents and examples teachers choose for their teaching and how they

justify their choices in an upper-secondary school biology course. Because many contents of

secondary school genetics can be taught in a human context, such as inheritance of genetic

disorders, we were also interested in how teachers perceive controversial and sensitive issues

during the biology lessons. As the Finnish upper secondary school curriculum provides ample

freedom for teachers to adopt the most suitable teaching methods and biology teachers are

generally educated broadly in different fields of biology, we were able to explore the

curricular genetics contents the teachers emphasise in their teaching and what are teachers'

perceptions of controversial and sensitive issues are their teaching.

Our research questions were:

1.   What do teachers suggest as the main contents of genetics teaching in the upper

secondary school in biology?

2.   How teachers argue for their use of human-related contexts in genetics teaching,

specifically in themes of GMOs, human hereditary disorders, and complex human traits?

3.   What kind of controversial or sensitive issues do teachers consider when teaching

upper secondary school genetics in general, and specifically, the subjects of GMOs, human

hereditary disorders, and complex human traits?

Methods

Overall study design

Our research design was a qualitative case study. We conducted open-ended semi-structured

interviews with 10 upper-secondary high school biology teachers from various schools from

Southern and Western Finland between 2015 and 2016 (see Table 2). Teachers were selected

purposively to reflect a variation in experience, gender, type of school and geographical

location to access different teachers with knowledge about upper secondary school biology

education. All teachers studied biology as a major subject in their university master's degree.

Additionally, we collected diary data and other teaching materials from teachers about how

they actually teach genetics.

We asked teachers' for their perceptions on their teaching in the framework of Finnish upper

secondary school biology and asked them to think about both compulsory BI2 and optional

BI5 courses. The main contents of genetics teaching were asked in this context (Research

Question 1). Furthermore, we asked teachers specifically how they teach and what examples

they use on three different human-related contexts: genetically modified organisms (GMOs),

human hereditary disorders and complex human traits, such as intelligence. These contexts

function as a gradient on how much freedom teachers have to choose what contents and

contexts they teach. The first context, GMOs, is explicitly mentioned in the national core

curriculum and teachers must discuss the ethics of GMOs. The second context, hereditary

disorders, is not mentioned in the curriculum, but most known examples of Mendelian genetic

traits in a human context are hereditary disorders. Thus, teachers can avoid this context, but it

is difficult. Thirdly, such complex human traits as intelligence are not mentioned in the

curriculum but this context can be used to discuss polygenic inheritance. Thus, teachers can

easily avoid this context and not use it all in their teaching. We asked teachers to explain their

reasons why they use these contexts or why they would not use them (RQ2). The idea behind

using this gradient of teacher freedom in relation to the curricula is to gauge how teachers

relate their view on what is important to learn in genetics to their own choices in contexts and

contents. Lastly, we asked teachers whether they perceived any controversial or sensitive

issues in their genetics teaching in general or specifically in these three contexts (RQ3).

Interviews

The interviews lasted from 40 minutes to 1 hour and 32 minutes. Teachers were asked: a)

what they perceive as the most important contents and contexts in genetics, b) how they

acquire knowledge for teaching and c) what examples they use during the two courses, the

BI2, for Cells and heredity course for all students, and BI5, an optional Biotechnology course

(Table 1). We specifically asked how teachers teach the topic of GMOs in the BI5 course and

what kind of examples of human genetics they use in courses BI2 and BI5.

Our aim was to learn how teachers justify their content and context choices in genetics

teaching. We used a theory-guided content analysis to categorize the data in a six-stage

process by following the ideas of abductive analysis laid out by Timmermans and Tavory

(2012): 1) we transcribed the interviews; 2) we coded the transcripts one sample at a time by

looking for our units of analysis: a) which subject matter teachers thought was the most

crucial and which could be left aside, b) how they argued for including or excluding certain

course content and c) how they described what they believe students feel important; 3)

beginning from the first sample, we named concepts arising from the grouped codes and after

each sample, recursively performed stages 2 and 3 for previously-coded samples (which

would correspond to initial analysis as per Charmaz (2003); 4) after initial samples were

coded and concepts named, we integrated the categories through a focused analysis; 5) we

contrasted the teachers to each other to understand the connections among categories, and 6)

we refined the model. We used the R (R Core Team, 2013) package RQDA (Huang, 2017) for

the analysis.

We contrasted the emerging codes with the assumption that teachers' content and context

choices are guided by the national and local curriculum, teaching materials and teachers'

personal knowledge. When coding content choices, three distinct groups emerged:

monohybrid crosses in humans, polygenic properties of humans and GMOs. Within these

three groups, we coded on later recursions all the mentions of the issues the teachers

described that a) they use in teaching, b) they avoid using in teaching, c) the topics in which

the students express interest and d) topics in which the students express no interest in. We

then simplified authentic expressions in the open codes to a combination that would describe

general-level biological phenomena, such as evolution, inheritance or gene expression. After

half of the samples were coded, selective coding was used to delimit the coding process.

Purposive sampling fitted well this research approach as our data becamerather rapidly

saturated: by the ninth sample, there was no new information useful for the category

formation. After the analysis, we asked teachers whether they agreed with our analysis of the

emphasis of their teaching.

Trustworthiness

228 To assess the connection between descriptions that the teachers gave of their teaching during

229 the interviews and their actual teaching, we asked the teachers to keep a diary of their

230 teaching after the interviews. We suggested that for each lesson the teachers record the topics,

231 teaching methods, textbook chapters and exercises that were discussed and about which topics

232 the students asked questions or needed clarification. Additionally, teachers who had ready-

233 made lecture slides sent those to us. An outside observer and first author classified diaries and

234 other materials based on the previously formed classifications (Table 2), which allowed us to

235 compare teachers' interviews and their actual teaching.

236 We continuously evaluated the trustworthiness of our study in several ways (Morrow, 2005).

237 During the category formation, we looked for disconfirming data and assessed data saturation.

238 The credibility was also enhanced by continuous discussion and revision of the meanings and

239 data coding during the categorization by the first author and the transcriber, who was a

240 sociolinguist. Transferability was improved by a rich description of the research process in the

241 form of an audit trail. The audit trail was drafted based on the memos and the developed

242 coding schemes. The authors evaluated the audit trail and agreed with research process.

243 [Table 2 here]

245          **Findings**

246 ***What do teachers suggest as the most important content in genetics courses?***

247 When we asked teachers to summarise what they hoped students would learn from upper-

248 secondary school biology courses, the teachers mentioned different contents (Table 2, Table

249 S1). We divided their answers to three distinct themes: 1) development of phenotype, 2)

250 inheritance and continuity and 3) structure and function of the genes. Some teachers gave

251 several descriptions that fitted two of these themes, but none described all three.

The first theme, development of phenotype, contains descriptions that focused on

understanding how genes and environment shape the development of different traits (i.e.,

genetic determinism). These descriptions were often related directly to how students

themselves have developed and to their understanding of how human individuals have

formed:

Teacher J: "Humans are constructed by many factors, of which genome influences

greatly, or they are things that we cannot influence ourselves; they come directly from

the genome, but also genes do not dictate how we live our lives, what kind of persons

we are, and how we behave."

The second theme, inheritance and continuity, is centred on the concept that there is genetic

continuity in the tree of life and that DNA copies itself from generation to generation.

Teachers who described concepts relating to this theme saw the understanding of evolution as

the focal point of whole field of biology and saw genetics as central to this understanding.

Biodiversity was mentioned as one manifestation of this continuity. Sometimes the

descriptions of the most important ideas were affective:

Teacher C: "The common thread of life, from the beginning, the same genes are

flowing; we are composed of genes from a million persons from thousands of years

and then a new combination pops up, from the stream of life."

The third theme, the function of the genes, was the simplest theme in terms teachers'

descriptions. They usually said that it was important to understand what genes are and how

they function, while offering no reference or reason why it is so. Some teachers mentioned

that in terms of general knowledge, it is important to know these topics.

Teacher B: "If I say it concisely, what the gene is and how it functions is the core

knowledge a student should have."

Use of human-related contexts in genetics teaching

GMOs

Most of the teachers approached ethical questions as being superimposed on the biological

content within a course and they thought the students should know the biological contents of

GMOs before discussing their ethical dimensions (Table S2). Some teachers also suggested

that students have highly polarised opinions on GMOs before coming to a course and that

"knowledge" could help them evaluate the different aspects of the debate.

Teacher F: "We have two types of students, so that they are pretty black-and-white.

Some of them have already been kind of brainwashed to think that "this is all great",

while a minority, or I don't know if they don't just dare to tell me, are against GMOs."

Three teachers said that they use SSI to motivate students at the beginning of the course,

while the other seven said that they first teach the biological content and then move to ethical

discussions. Still, ethical questions were seen as secondary to biological content:

Teacher J: "…there's not always much time for discussions – the time spent in ethical

discussions is always reduced from less than what is spent on the course texts."

Human genetics

Teachers mentioned that the use of human examples in genetics is mostly limited to

Mendelian disorders in the BI2 course (Table 2, Table S3) and more complex traits are then

discussed at the end of BI2 or during the BI5 courses (Table 2, Table S4). Teachers

commonly held the opinion that students are interested in hereditary phenomena in general

(Table S5), but there is mismatch between how textbooks frame genetics and the students'

interests: while students are mainly interested in human genetics, the textbooks lack good

examples and teachers did not feel themselves competent to go deeper into the topic:

Teacher J: "… [a student asks] if I have blue eyes and my boyfriend has brown eyes,

then what colour will our children's eyes be, but unfortunately I have to try to contain

their excitement as I don't know the answers to their questions."

Some teachers mentioned that they use classic, if not the most correct, examples like hair with

a widow's peak or the ability to roll the tongue. All teachers who used these examples said

that, nevertheless, they mention to students that genetics is generally not that simple.

Two teachers mentioned that they try to avoid the human context in general and three other

teachers said that they try to avoid discussing complex human traits, such as talent,

intelligence, or human behaviour (Table 2, Table S6):

Interviewer: Do you discuss how genetics affects learning? What if some students

have genes that allow them to achieve better grades?

Teacher E: No, no. (pause). No.

Interviewer: No?

Teacher E: No, we do not discuss that.

Interview: No one is interested?

Teacher E: No. I am not interested either (laughs)

Interviewer laughs

Teacher E: I think it is extremely sensitive issue. I would reconsider several times

before discussing it.

Most teachers said that they discuss human behavioural genetics if students ask questions, but

they do not introduce the topic themselves. In contrast, some teachers said the discussions are

needed, especially in the context of racial issues:

Teacher D: "It is relevant for the students if it is discussed in public, societal debate –

[they may want to know if] citizens from certain continents are less intelligent than

others–, and we have discussed these alternative news a lot, how they publish utter

nonsense."

Controversial or sensitive issues in genetics

Half the teachers did not identify any sensitive or controversial issues thatthey would avoid

(Table 2, Table S6). Among the other half there were differences in how they framed sensitive

and controversial issues. Most of the argumentation was related to what is seen as biological

general knowledge or avoiding misconceptions on genetics: teachers mentioned or implied

that human traits are inherently so complex that there is a significant risk that students would

form misconceptions on overtly genetic determinations of these traits. Furthermore, the lack

of examples and lack of teacher competence was seen as leading to teaching without

meaningful contents. The two teachers who avoid the topic humans as a context argued that

humans are just one species, and it is not meaningful to concentrate too much on humans in

biology.

Additionally, teachers mentioned that some issues cause discomfort for them or their students.

Regarding students, some teachers acknowledged that discussing human heredity can pose

several challenges (Table 2, Table S6). For example, using blood group testing can raise

questions and even distress students if their blood group is not concordant with their parents'

blood groups. One teacher mentioned she does not want to do pedigrees on simple traits with

students because of the "diversity of families" and she does not know the students'

backgrounds. The reason for describing these issues as "uncomfortable" was framed as a

question of a teacher not knowing how to deal with discussing these issues or encountering

unexpected reactions from the students. Those teachers willing to discuss genetic disorders of

students or their families argued that generally those affected know best about the issues. One

teacher also mentioned that sensitive issues bring up emotions, but that it is also natural in a

classroom setting:

Teacher C: "Sometimes I've gone and hugged a student – I find it a good way to calm

down. – Every now and then I have tears in my eyes, but I think it's important to show

my own emotions in my teaching."

Teachers frame genetics teaching with different emphases

Teachers' perceptions of the most important genetic content were closely related to their

willingness to use a human context in their teaching or even what they said that students find

interesting (Table 2). For example, none of the teachers whose theme in genetics teaching was

classified as "development of phenotype" mentioned that they try to avoid human complex

traits. In turn, both teachers who said that students are interested in gene testing had their

theme grouped to "inheritance" and both teachers who mentioned students are interested in

epigenetics to "development of phenotype."

Three different general frameworks of teaching genes and their role arose from the analysis:

Developmental, *Structural* and *Hereditary* (Table 3). We call these emphases of contents in

genetics teaching, as they relate to how teachers argue not only for their choice of contents

and which they see as the most important contents or themes, but also which contexts they

use. They also reveal how they perceive student interest and whether they avoid certain

topics. Furthermore, they align with perception of sensitive or controversial issues. We note

that these emphases do not consider how teachers understand genes or their function, but

rather what teachers see genetics to constitute from a teaching perspective.

A *Developmental* emphasis frames the development of traits as the central theme in genetics

and consequently teachers who used this approach were largely open to any discussions, they

did not mention any topic they would avoid and most of them mentioned that they have

regular discussions about complex human traits as they felt that students are most interested in

these. Furthermore, teachers with *Developmental* emphasis were less likely to describe any

perceived sensitive issues than other teachers (Table 2). These teachers were all

comparatively the less experienced teachers of the interviewed group (12 or fewer years of

experience). Their emphasis contrasts with two teachers who used a *Structural* emphasis

mentioning only gene function as the central issue. These teachers mentioned avoiding

discussing complex traits in humans or humans at all, as they found these both sensitive and

not good examples of polygenic inheritance. In contrast, these teachers described hereditary

analysis as an interesting part of the genetics course. They were among the most experienced

teachers (> 20 years). A third emphasis, *Hereditary*, was characterised by emphasis on the

continuity of DNA through the whole tree of life. This emphasis manifested in teachers'

answers as being somewhere between the two previous emphases. Teachers who used this

emphasis were willing to discuss complex human traits if the students asked about them, but

did not actively raise examples. They generally used an example of human skin colour as an

example of a polygenic trait. More broadly, in genetics, they usually emphasised the

understanding of phenomena related to DNA duplications, such as meiosis. A hereditary

emphasis was used by both less and more experienced teachers.

[Table 3 here]

In contrast to the issues involving the human complex traits, genetics content emphasis was

not connected to how teachers taught GMOs (Table S2). While some teachers were more

dismissive about teaching on SSI while discussing GMOs and said that there was not always

time to go through those topics, they were not differentiated based on their genetics emphasis.

Furthermore, one teacher who said that they use GMOs as a motivation at the beginning of the

course to explain how genetics are important, said that they do not always have time to go

into the ethics of GMOs. In general, lack of time is a general perception of teachers in

different subjects and countries (Adams & Krockover, 1997; Archbald & Porter, 1994; Fuller,

1969) and the interviewed teachers also expressed this phenomena repeatedly. Most teachers

mentioned lack of time and the need to closely follow the textbook were mentioned by most

teachers, and noted that textbooks tend to discuss ethical dimensions of biotechnology at the

end of the text (Aivelo & Uitto, 2015).

Teacher self-identification and relationship to actual teaching

When we provided teachers with the descriptions of the genetics emphasis and our analysis of

their interview, six teachers agreed with our analysis, three teachers disagreed and one teacher

was unavailable (Table 2). All disagreeing teachers had their teaching emphasis labelled to

Developmental. Two of the teachers also argued for that their emphasis was not the one they

would have preferred for genetics teaching, but it was mostly dictated by national curriculum,

which mentions evolution and development in different courses.

We obtained teaching diaries and other teaching materials with enough information for our

analysis from five teachers. In categorization, the interrater reliability was high (Cohen's

kappa: 0.88). The concurrence between the interviews and the diaries was variable as some

teachers were fully concordant (such as teachers B and H), whereas Teachers G and J had two

discordant categorizations (Table S7). In total, 18 of 22 units were concordant between the

interviews and diaries.

Factors behind teachers' choice of content

Although there were significant differences in teachers' emphasis in genetics teaching, there

were some similarities in their arguments on factors influencing their content choices (Table

2). While the teachers described their teaching in quite different terms, all except teacher E

said that 1) they follow closely the textbook content. Because the contents of biology

textbooks for upper-secondary schools is highly similar (Aivelo & Uitto, 2015), teachers

clearly had different personal priorities on the most important contents and contexts. All

schools follow 2) the national core curriculum (FNBE, 2004), and this was evident in

teachers' descriptions of their content choices (Table 2, 3). Furthermore, this was emphasised

by the inclusion of GMOs in the biology core curriculum by all teachers (Table 3). The

national core curriculum is also the basis for the tasks on the matriculation examination that

the students take at the end of the upper-secondary school in Finland (Niemi et al., 2012) and

teachers acknowledged that 3) previous exam questions guide their teaching.

The aforementioned factors were quite similar for each teacher, but our results also reveal

perceived differences among teachers and the 4) school-specific circumstances in which they

are working. Some of the teachers compared their school to other schools and suggested that

some attributes of their school attract students with specific interests or motivation or

competence to study biology. Likewise, teachers described differences in course

arrangements, and noted whether it was possible to conduct experiments in the classroom.

Furthermore, teachers expressed that there are 5) personal reasons that affect their course

content selection. On many occasions the teachers acknowledged the limits of their

competence, either regarding genetics contents, such as when they are unable to answer

students' complicated questions of the students, or pedagogically, when they mentioned they

might have problems in successfully guiding classroom discussions.

437   **Discussion**

Teachers' emphasis in genetics

Our findings suggest that there were fundamental differences in Finnish upper secondary

school biology teachers' perceptions on the most important themes in genetics and genetics

teaching and subsequently how they chose course content and context while teaching

genetics. The perceptions can be classified to three distinct areas of content emphasis, which

we named *Structural*, *Hereditary* and *Developmental*. These emphases are formulated on the

basis of how teachers interpret and use 1) the central themes in genetics, 2) human contexts in

their genetics teaching, 3) students' interest in different contents and contexts and 4)

perceptions of sensitive or controversial issues in genetics.

Our findings are partly like those of Van Driel et al. (2007), who found separate subgroups of

teachers who were either subject-matter oriented focusing on fundamental, theoretical

concepts or learner-centred emphasising societal issues. While *Structural* emphasis can be

seen as subject-matter oriented, *Developmental* emphasis is not learner-centred in similar

sense as in the study by Van Driel et al., as the orientation is not as much societal as it is

personal. Stewart, Cartier and Passmore (2005) outlined three different models of genetics

understanding: inheritance pattern, meiotic and biomolecular. These models are quite close to

our concept of content emphasis: inheritance patterns model and *Hereditary* emphasis are

similar. *Structural* resembles the meiotic model while *Developmental* has less in common

with the biomolecular model.

The diversity of emphases can be explained by the complex educational context in the Finnish

upper secondary school, which aims not only to train students for tertiary education, but also

to develop scientific literacy in those students who may not study biology further. The biology

course "Cells and heredity" is compulsory for all students of which approximately one-third

complete the biology part of the matriculation examination (Matriculation Examination

Board, 2019). Thus, the teachers balance what Roberts (2007) referred to as vision I (as

knowledge within science) and vision II (as knowledge in everyday situations) of scientific

literacy.

Moreover, genetics content emphasis can be seen as partly overlapping with "science teaching

orientations" (Magnusson, Krajcik, & Borko, 1999) as they contain knowledge of the

importance of different concepts, interpretation of curricula, the motivations of the students,

and representations and context of core concepts. In comparison, while the science teaching

orientations describe teachers' perceptions about teaching and especially instruction methods,

we did not find that genetics content emphasis would limit the instruction methods.

Nonetheless, the different emphases rises the question of how differential teacher

understanding of core concepts and contexts influences teaching methods or orientations to

teaching science. In a follow-up study, we aim to study teachers' gene concepts and whether

they relate to a different emphasis.

Human-related contexts involve controversial and sensitive issues

Our research setting in comparing three different human-related contexts - GMOs, Mendelian

human traits and complex human traits - contrasts the effects of curriculum-dictated context

choice and free choice by teachers, and highlights the difference between personal and

societal relevance. Our interviews showed a paradoxical approach by teachers: while they said

that genetics is a societally relevant topic, and that students should learn analytical tools to

take part in decision-making and be responsible consumers, this was not evident in their

descriptions of their teaching. Without exception, teachers formulated the basic science as the

main issue and, in many cases, societal aspects of GMOs were described to be taught only "if

there was time at the end of the course." Our results agree with Tidemand and Nielsen's

(2017) suggestion that emphasis on biological content (as opposed to more societal context) is

driven by teachers' identity as biology teachers (see also Pedretti, Bencze, Hewitt, Romkey, &

Jivraj, 2008). Nevertheless, all teachers did teach GMOs as they are explicitly mentioned in

national curriculum.

In comparison, some teachers described avoiding human genetics contexts that could be seen

as personally highly relevant to students. These teachers were also more likely to describe

controversial or sensitive issues related to genetics teaching. It is noteworthy, that teachers

framed sensitive issues in human genetics in relation to students personally, as something that

concerns individual students and not so much the society at large. Thus, in Rowling's (1996)

categorization, the teachers were more worried about sensitive issues than controversial

issues. Furthermore, this suggests that there is a trade-off between personal relevance to

students and perceived problems arising from sensitive issues. As this was not mentioned in

relation to GMO teaching, teachers seem to be more hesitant about this personal relevance,

rather than societally controversial issues.

The avoidance of human contexts is a complex issue as teachers used numerous reason for

steering clear of topics in human genetics context, for example: a) students are not interested

in these topics, b) teachers do not have enough content knowledge, c) teachers do not have

pedagogical knowledge for teaching sensitive issues and d) courses discussing genetics in

human context would lead to negative learning outcomes, such as misconceptions. In general,

controversial issues were thought to lead to misconceptions, whereas sensitive issues were

seen to lead to awkward situations for individual students. We are not able to assess how

relevant these various factors are, but it is clear from our content emphasis classification that

there are fundamental differences in how teachers perceive the most important contents and

contexts in genetics. Furthermore, contrary to the previous studies (Hess, 2008; Phillips,

1997), our study suggests that Finnish teachers are open to discuss complex human traits and

other sensitive issues in classroom even when they are not experienced.

Limitations of the study

While the number of interviews in our study is limited, we reached data saturation rapidly.

One reason for this may be the similarities in the educational background of the teachers, as

all of them had a master's degree with biology as the major subject, and pedagogical studies

in teacher education as a minor subject. Moreover, the textbooks used by the teachers are

quite similar, emphasizing gene structure and function (Aivelo & Uitto, 2015). Due to the

small number of participants and limited knowledge on teachers' background, the

generalizability of this study is limited and we cannot discuss other factors than those

mentioned by the teachers: namely, the role of the chosen textbooks, biology curriculum,

practicing for the matriculation examination and school-specific and personal factors. The

interpretive disagreements on genetics content emphasis between some teachers and

researchers were all related to a *Developmental* emphasis. Nevertheless, the interrater

reliability in categorization and the concordance between teacher interviews and diaries was

rather high.

Potential sources of bias were minimized by allowing the interviews to be as freely advancing

as possible and questions were designed to prevent confirmation bias by probing for

disconfirming answers and leading questioning by beginning each strain of questions with

general questions. Research positionality was reflected regularly through interactions between

the authors and in discussions with outside researchers and biology teachers. The authors have

multi-faceted relationship towards participant community as they are involved in teacher

education and in-service teachers' continuing education and both have backgrounds as upper-

secondary school biology teachers. Both authors have also been involved in the national core

curriculum process. Thus, the authors are insiders in the participant community but also hold

positions of power. This setting was approached by emphasizing to teachers that they are

experts in teaching practice and that the researchers were genuinely interested in their

answers.

Implications for research and teaching practice

The national curriculum for upper-secondary schools gives substantial freedom to teachers to

interpret the contents and goals of biology education in classroom practice (FNBE, 2004;

Niemi et al., 2012). This may partly explain the fundamental differences in content emphasis

that we found. Consequently, in school practice, teacher education and in-service training, the

teachers should be made more aware and provide opportunities for self-reflection on the

emphasis they take in teaching science.

We also suggest that our findings on which contents teachers choose for their teaching

provides a well-grounded hypothesis for further research on the content perspective of

experienced, autonomous biology teachers. The relationship between content emphasis and

the choice of course content could provide a more widely applicable hypothesis for studying

teaching and learning genetics in biology education, because teachers have freedom to choose

whether to apply a sensitive human context to their teaching.

Considering GMO SSIs being integrated in the teaching, independent of teacher inclinations,

we suggest that curriculum development would be a valuable tool if genetics education aims

to better incorporate societal and personal relevance. Furthermore, curriculum development

needs to relate to teacher education emphasizing pedagogical content knowledge (Käpylä,

Heikkinen, & Asunta, 2009). While teachers appreciate a "knowledge first" approach to SSI

and avoidance of human related topics, there is a perceived lack of useful and tested teaching

materials. Content knowledge is important for successful reasoning regarding SSI: thus, a

delicate balance needs to be sought (Lederman et al., 2014; Sadler & Zeidler, 2004)

From our interviews, it is clear that personal relevance in teaching can have various effects in

the classroom: while some teachers see it as a possibility, some seem to avoid it for a number

of reasons. This topic needs to be addressed more in professional development. In general, the

ways of teaching controversial and sensitive issues are not well-studied and the

recommendations themselves are controversial (Christopher Oulton et al., 2004). Thus, both

societal and personal relevance should be taken more into account in science and especially in

biology teacher education and in-service training.

Conclusions

Based on qualitative case study and teacher interviews, we have found that teachers'

perceptions of genetics teaching reflected three different emphases that we named as

Structural, *Hereditary*, or *Developmental* content emphasis. These emphases consist of

teachers' perceptions of the most important themes in genetic content, willingness to teach

about human traits, perceived sensitive or controversial issues in genetics and students'

perceived interests. Interestingly, teachers having *Structural* emphasis described avoidance of

a human genetics context in their teaching, while teachers with a *Developmental* emphasis

described very abundant use of human genetics contexts. Thus, teachers' perceptions of which

themes in genetics are the most important could also shape how likely they are to use

personally relevant contexts in their teaching. As we did not observe the actual teaching

practice, we do not know how well these emphases manifest in teaching itself and whether

these have an actual effect on student learning outcomes. Our ongoing research project could

shed light on this by comparing student interests and attitudes to their teacher's genetics

content emphasis. Nevertheless, we suggest that teachers' perceptions on the most important

themes in their teaching can have wide-ranging consequences, for example, inclusion of

socioscientific issues in the teaching.

Our results also revealed different approaches to the sensitive and controversial issues in

genetics teaching. Not all teachers perceived that sensitive or controversial issues would affect

their teaching and those who did, usually described sensitive rather than controversial issues,

thus suggesting that teachers are more worried about personal issues in genetics. Indeed,

sensitivity was sometimes used as a justification to exclude contents or contexts that are

personally relevant to genetics teaching. We note that teachers would need more support to

handle controversial and sensitive issues in the classroom. In contrast to personally relevant

human genetics, the Finnish curriculum specifically mentions GMOs and compels teachers to

discuss them. Subsequently, every teacher mentioned that they discuss GMOs. Thus, we also

argue that curricular development is an effective way to increase the prominence of societal or

personal relevance in biology education.

594   **Acknowledgments**

595   The authors wish to thank the ten biology teachers who participated in this study, Marlene

596   Broemer for checking the language in manuscript, Lotta Aarikka for transcribing the

597   interviews and providing debriefing during initial analysis, Justus Mutanen for teaching diary

598   analysis and fruitful discussions and Niklas Gericke for comments on an earlier version of the

599   manuscript.

600   **Disclosure statement**

601   Tuomas Aivelo has participated in writing biology textbooks for upper-secondary school

602   biology for eOppi Oy. None of the teachers involved in this study used biology textbooks

603   from eOppi Oy.

605   **Appendix**

Supplemental material in Figshare includes following tables containing representative quotes

from teacher interviews:

Table S1: Teacher's descriptions of the central theme of their teaching.

Table S2: Teacher's descriptions of GMOs in their teaching.

Table S2: Teacher's descriptions of the human Mendelian disorders in their teaching.

Table S3: Teacher's descriptions of the complex human traits in their teaching.

Table S5: Teacher's descriptions of the perceived student interest in genetics.

Table S6: Teacher's descriptions of perceived sensitive issues.

Table S7: The concurrence between teaching diary and other materials in comparison to

teacher interviews.

Table 1: The Core content described in the Finnish national curriculum with selected parts
from courses BI2 and BI5

Topics	BI2—Cell and genetics *Mandatory course*	BI5—Biotechnology *Optional course*
DNA and genes	DNA structure and function	DNA, gene and genome structure
	Genes and alleles	
	Protein synthesis	Gene function and regulation
Cell functions	Gametes and meiosis	
	Mitosis	
Inheritance	Inheritance mechanisms	
	Population genetics	
Applications		Gene technology
SSI		Ethics and legal issues in gene technology

770   Table 2: Summary of interviews of ten interviewed teachers. For details, see the supplemental material.

Teacher	Gender	Central theme of teaching	Examples of Human Mendelian traits	Examples of Complex human traits	Perceived controversial or sensitive issues	Perceived student interest	Genetics content emphasis	Teacher concurrence with analysis
A	Female	Development of phenotype	Disorders, lactose intolerance	Life style diseases	None	Artistic talent, epigenetics	Developmental	Yes
B	Male	Development of phenotype	Disorders, blood groups, tongue roll	Height, skin colour, talent	None	Epigenetics, talents, monohybrid crosses	Developmental	Yes
C	Female	Inheritance and continuity	Disorders	Eye color, **generally avoid**	Intelligence	Gene tests	Hereditary	Yes
D	Male	Inheritance and continuity	Disorders	Height, skin colour	Human race-related	Medical genetics	Hereditary	No answer
E	Male	The structure and function of genes	Eye colors, **generally avoid**	Shoe size, **generally avoid**	Intelligence	Mono- and dihybrid crosses	Structural	Yes
F	Female	Development of phenotype	Disorders, tongue roll, widow's peak	Height	None	Challenging contents	Developmental	No; Structural
G	Female	The structure and function of genes	Tongue roll, eye colors, **generally avoid**	Height, hair coloration, **generally avoid**	Intelligence, talent, genetic disorders	Mono- and dihybrid crosses	Structural	Yes
H	Female	Inheritance and continuity	Tongue roll, ear lobe	Skin color, generally avoid	None mentioned	Inheritance patterns	Hereditary	Yes
I	Male	Development of phenotype	Disorders	Stress reaction, intelligence	None	Sex-related traits	Developmental	No; Structural
J	Female	Development of phenotype	Disorders, eye colour, ear lobe	Height, skin colour	Developmental disorders	Musicality, own complex traits	Developmental	No; Hereditary

771   Table 3: Three different content emphasis and the teacher perceptions and descriptions which

772   differ between emphasis.

Content emphasis	Structural	Hereditary	Developmental
Central theme	Gene structure and function	Continuity of DNA through time	Development of traits
Human context			
1. Human Mendelian disorders	Avoid	Use as examples	Use as examples
2. Complex human traits	Avoid	If students ask	Use as examples
Perceived student interest	Monohybrid, dihybrid crosses	Gene tests, medical genetics	Epigenetics, complex human traits
