29 **Highlights:**

30 This is the first article that explores the effects of DCPTA on nitrogen metabolism and
31 the first article that explores the effects of DCPTA on crops under soil drought
32 conditions.

33 **Abstract**

34• 2-(3,4-Dichlorophenoxy) triethylamine (DCPTA) regulates many aspects of plant
35 development; however, its effects on soil drought tolerance are unknown. We
36 pre-treated maize (*Zea mays* L.) by foliar application of DCPTA and subsequently
37 exposed the plants to soil drought and rewatering conditions during the pre-female
38 inflorescence emergence stage. Exogenous DCPTA significantly alleviated
39 drought-induced decreases in maize yield, shoot and root relative growth rate (RGR),
40 leaf relative water content (RLWC), net photosynthetic rate (Pn), stomatal
41 conductance (Gs) and transpiration rate (Tr), nitrate (NO₃⁻), nitrite (NO₂⁻), and soluble
42 protein contents, and nitrate reductase (NR), nitrite reductase (NiR), isocitrate
43 dehydrogenase (ICDH), alanine aminotransferase (AlaAT) and aspartate
44 aminotransferase (AspAT) activities; increases in the intercellular CO₂ concentration
45 (Ci), the ammonium (NH₄⁺) and free amino acid contents, and the glutamate
46 dehydrogenase (GDH) and protease activities. Simultaneously, exogenous DCPTA
47 improved the spatial and temporal distribution of roots and increased the root
48 hydraulic conductivity (Lp), flow rate of root-bleeding sap and NO₃⁻ delivery rates.
49 Moreover, Exogenous DCPTA protected the chloroplast structure from drought injury.
50 Taken together, our results suggest that exogenous DCPTA mitigates the repressive
51 effects of drought on N metabolism and subsequently enhances drought tolerance
52 during the pre-female inflorescence emergence stage of maize.

53 **Key words:** DCPTA; maize (*Zea mays* L.); nitrogen metabolism; pre-female
54 inflorescence emergence stage; soil drought; yield

55

56

57 **Introduction**

58 Crops are frequently exposed to drought during the growth period because of
59 limited and erratic rainfall patterns due to global climate change, which leads to
60 restrictions on agricultural productivity worldwide (Trenberth *et al.*, 2014). Maize
61 (*Zea mays* L.), an essential component of global food security, is widely cultivated
62 around the world. The majority of the cultivated area of maize is almost wholly
63 rain-fed and experiences sporadic drought and rewetting cycles (Nuccio *et al.*, 2015).
64 However, maize is considered to be a drought-sensitive crop and loses approximately
65 1/4 potential yield annually due to drought (Ziyomo and Bernardo, 2013). By 2050,
66 the world population will reach 9 billion people, resulting in a high demand for maize
67 (projected to double); furthermore, at that time, drought will severely restrict crop
68 growth for more than 50% of the cultivated land (Schiermeier, 2014).

69 To stabilize and increase global crop production to satisfy the demand of the
70 globally burgeoning population, it is imperative to design agronomic research to
71 improve maize performance under drought stress (Zhao *et al.*, 2018). The application
72 of plant growth regulators has been considered an effective way to enhance crop
73 drought resistance (Ali *et al.*, 2017). Multiple investigations have indicated that a
74 tertiary amine bioregulator known as 2-(3,4-dichlorophenoxy) triethylamine (DCPTA)
75 regulates many aspects of plant development; for example, DCPTA promotes plant
76 growth (Keithly *et al.*, 1990a), enlarges chloroplast volume (Keithly *et al.*, 1990b),
77 enhances photosynthetic enzyme activity (Wan and Mendoza, 1992), accelerates CO₂
78 fixation (Gausman *et al.*, 1985), and stimulates carotenoid biosynthesis (Benedict *et*
79 *al.*, 1985). As far as we know, very few studies of DCPTA have focused on crops, and
80 the effect of DCPTA on crops exposed to soil drought are still unclear.

81 Nitrogen (N) metabolism is a fundamental process in determining the growth and
82 productivity of plants (Kusano *et al.*, 2011). After being taken up by root systems,
83 nitrate (NO₃⁻) is converted to nitrite (NO₂⁻) by nitrate reductase (NR), the first step of
84 N uptake and utilization. Subsequently, nitrite (NO₂⁻) is converted to NH₄⁺ by nitrite
85 reductase (NiR) with reduction-ferredoxin (Fd_{red}) as an electron donor (Rajasekhar *et*

86 *al.*, 2010). Afterward, the ammonium (NH_4^+), derived from NO_3^- reduction,
87 photorespiration and/or other metabolic processes is assimilated into glutamine by the
88 glutamine synthase/glutamine oxoglutarate aminotransferase (GS/GOGAT) cycle or
89 the alternative glutamate dehydrogenase (GDH) pathway with 2-oxoglutarate (2-OG)
90 and reducing equivalents provided by photosynthesis (Chardon *et al.*, 2012).
91 Subsequently, glutamate serving as a donor of the amino group is used for the
92 synthesis of other amino acids, which are used for the synthesis of various organic
93 molecules such as chlorophyll, proteins and nucleic acids. The reactions are catalysed
94 by aminotransferases such as alanine aminotransferase (AlaAT) and aspartate
95 aminotransferase (AspAT) (Slattery *et al.*, 2017).

96 Drought disrupts N metabolism mainly via inhibiting the uptake and/or
97 long-distance transportation of NO_3^- (Nacer *et al.*, 2013), altering the activities of
98 enzymes involved in N metabolism (Robredo *et al.*, 2011), inhibiting amino acid
99 synthesis, and promoting protein hydrolysis (Fresneau *et al.*, 2007). At present, the
100 study of plant growth regulators mainly concentrates on the improvement of
101 photosynthesis and antioxidant systems, and there have been only a limited number of
102 publications related to N metabolism.

103 Our previous hydroponic trial found that exogenous DCPTA drastically
104 promoted growth under non-stress conditions and mitigated the PEG-simulated
105 drought-induced growth inhibition of maize at the seedling stage (Xie *et al.*, 2017).
106 The present study was conducted to explore whether DCPTA can alleviate soil
107 drought injuries to maize and whether the effects are associated with the modulation
108 of nitrogen metabolism.

109 **Materials and Methods**

110 **Plant material, growth conditions, design and sampling**

111 Seeds of the maize cultivar ZhengDan 958 and DCPTA were obtained from the
112 Henan Academy of Agricultural Sciences in China and the China Zhengzhou
113 Zhengshi Chemical Limited Company, respectively.

114 These experiments were performed in 2016 and 2017 at the Experimental Station

115 of Northeast Agricultural University, Harbin (126°73'E, 45°73'N), Heilongjiang
116 province, China. The research field area has a temperate continental monsoon climate.
117 The rainfall and mean temperature data during the study period (2016 and 2017,
118 May–October) are listed in Fig. 1. Pits (inner length, 10 m; width, 7 m; and height, 1.2
119 m) in the field were used as experiment containers (Fig. 2). Plastic sheets were used to
120 cover the inner sides of the pits, and a rain-proof shed was used to ensure the crops
121 were solely dependent on soil moisture and irrigation over the course of the
122 experiment to maintain the soil water conditions. The soil used was Chernozem and
123 was sieved (pore size, 1 cm) and diluted with vermiculite (particle diameter, 4-8 mm;
124 soil to vermiculite, v/v, 2:1). Before planting, soil chemical analysis was conducted
125 according to Cottenie *et al.* (1982), and the results are presented in Table 1.
126 Fertilization was carried out by adding ammonium nitrate (33.5% N), calcium
127 superphosphate (15.5% P₂O₅), and potassium sulfate (48% K₂O) at the rates of 8.0,
128 8.0 and 20 kg pit⁻¹, respectively, before planting. No fertilizer was applied after
129 planting. All containers were watered to 85% before planting. The seeds were
130 manually sown on 2nd May 2016 and 4th May 2017 and were harvested on 7th
131 October 2016 and 3rd October 2017, respectively. Three seeds were sowed per hole to
132 ensure germination, and only the healthiest seedling within 20 days was kept at each
133 site. Each container consisted of 10 rows, and the plant-to-plant and row-to-row
134 distances were 20 cm and 65 cm, respectively. In addition, the ground around the
135 containers was manually sown with the same plant-to-plant and row-to-row distances.
136 The control of plant diseases and insect pests was conducted by managers.

137 The maize at the nine-leaf stage (during the pre-female inflorescence emergence
138 stage) were treated as follows:

139 (1) plants were irrigated continuously and sprayed with either 10 mL water
140 (well-watered) or DCPTA (well-watered+DCPTA) per plant;

141 (2) irrigation was stopped to form the drought conditions and sprayed with 10
142 mL of either water (drought) or DCPTA (drought +DCPTA) per plant; plants were
143 rehydrated after 20 days of drought treatment.

144 The concentrations of DCPTA (25 mg/L) were based on the results of
145 previous screening experiments, and Tween-20 (0.03%) was added as a surfactant to
146 the solution for spraying. Each treatment had five replicates, and experiments were
147 performed in a completely randomized design. The dynamic changes in soil water
148 contents during the experimental stage are exhibited in Fig. 3.

149 Random plants from each treatment were sampled on days 0, 5, 10, 15, 20, 25
150 and 30. For leaf sampling, the middle part of the 9th leaf (numbered basipetally) was
151 sampled for analysis of leaf gas exchange, and the same part of the leaf was stored at
152 -80°C after immersion in liquid nitrogen for 30 min for determination of physiological
153 parameters. For root sampling, a hand-held soil auger (inner diameter of 20 cm) was
154 used to obtain soil cores from 0 to 100 cm depth of the soil profile at 10 cm increments.
155 The soil cores were soaked in a plastic container overnight, and roots were stirred and
156 sieved through a mesh (400 holes cm⁻²). The soil cores were carefully washed by
157 swirling water through the cores. The soil material and old dead roots debris were
158 manually separated from the live roots.

159 **Plant measurement and analysis**

160 **Relative growth rate (RGR) and plant productivity**

161 The shoots and roots of maize were oven dried at 105°C for 45 min and then
162 held at 80°C for 48 h; the shoot and root dry weights plant⁻¹ were determined soon
163 afterwards. The RGR was determined as follows: $RGR \text{ (fresh weight)} = [\ln(\text{final dry weight}) - \ln(\text{initial dry weight})] / (\text{duration of treatment days})$ (Kingsbury *et al.*, 1984).
164 A leaf area metre (Li-COR 3100; Li-COR, Lincoln, NE, USA) was used to estimate
165 the leaf area; number of grains plant⁻¹ (GN) and grain yield plant⁻¹ (GY) were
166 recorded at the maize physiological maturity stage.
167

168 **Leaf relative water content of (RLWC) and soil water content (SWC)**

169 The RLWC was determined on fresh leaf disks (2×2 cm) from the middle part of

170 the 8th leaves (numbered basipetally). After they were weighed (FW), the disks were
171 immersed in distilled water at 25 °C overnight to obtain the turgid weight (TW). The
172 leaves were dried at 80°C for 48 h and then weighed a third time (DW). RLWC was
173 calculated as follows:

$$174 \quad \text{RLWC (\%)} = [(FW - DW) / (TW - DW)] \times 100.$$

175 SWC was determined in the soil from the internal area of each container. After
176 being weighed (FW), the soil portion was dried at 85°C for 96 h and then weighed
177 (DW). SWC was calculated as follows:

$$178 \quad \text{SWC (\%)} = [(FW - DW) / DW] \times 100.$$

179 **Gas exchange**

180 The photosynthetic rate (Pn), transpiration rate (Tr), stomatal conductance (Gs),
181 and intercellular CO₂ concentration (Ci) values were determined with a portable
182 photosynthesis system (LI-6400XT; LI-COR Biosciences, Lincoln, NE, USA)
183 between at 13:00~14:00 h. The 6-cm² leaf chamber was used, and the photo flux
184 density was 1000 $\mu\text{mol m}^{-2}\text{s}^{-1}$.

185 **Transmission electron microscopy of chloroplasts**

186 Observations were performed according to the description of Hu *et al.* (2014), and
187 the chloroplast ultrastructure was observed under a H-7650 transmission electron
188 microscope (manufacture: Hitachi, Japan).

189 **Root morphological traits, root hydraulic conductivity, and the collection of** 190 **root-bleeding sap**

191 Roots from each soil core were scanned using a digital scanner (Epson V700,
192 Indonesia). The root images were analysed using the WinRHIZO Image Analysis
193 system (Version 2013e) (Regent Instruments Inc., Canada). The root length density
194 (RLD, cm root cm⁻³ soil) and root square area density (RSD, cm² root cm⁻³ soil) were
195 calculated according to the method described by Mosaddeghi *et al.* (2009).

196 The hydrostatic root hydraulic conductivity (L_p) was measured with a
197 Scholander pressure chamber according to the method described by López-Pérez *et al.*
198 (2007).

199 The plants were cut by scissors at 10–12 cm above the soil surface at 18:00-19:00.
200 Centrifuge tubes (inner diameter 40 mm) with cotton were placed on the upper end of
201 the stalks, and the stalk joints and centrifuge tubes were wrapped by plastic film to
202 keep impurities and insects out (Fig. 4). The bleeding sap was collected for 12 h; then,
203 the cotton was extracted from each centrifuge tube and placed into a glass syringe
204 (100 ml), and the root-bleeding sap was squeezed out for volume measurement. The
205 NO_3^- content in the root-bleeding sap was determined by AA3 Continuous Flow
206 Analytical System (Seal, Germany) according to Guan *et al.* (2014). The flow rate of
207 the root-bleeding sap and the NO_3^- delivery rate were expressed as $\text{ml h}^{-1} \text{root}^{-1}$ and
208 $\mu\text{g h}^{-1} \text{root}^{-1}$, respectively.

209 **Foliar NO_3^- , NO_2^- and NH_4^+ contents**

210 The foliar NO_3^- content determination by the reduction of NO_3^- to NO_2^- followed
211 the salicylic acid methods of Cataldo *et al.* (1975), the absorbance was monitored at
212 410 nm. The foliar NO_2^- content was determined using the method described by Barro
213 *et al.* (1991). The NO_2^- content was calculated according to the standard curve
214 obtained by known concentrations of KNO_3 . The NH_4^+ content was determined by
215 measuring the absorbance changes at 620 nm, as described by Weber (2007). The
216 NH_4^+ content was calculated according to the standard curve obtained by known
217 concentrations of $(\text{NH}_4)_2\text{SO}_4$.

218 **Enzyme activities involved in nitrogen metabolism**

219 The activities of foliar NR and NiR were measured based on the conversion of
220 NO_3^- to NO_2^- and NO_3^- to NH_4^+ , following the methods of Barro *et al.* (1991), and Ida
221 and Morita (1973), respectively. One NR and NiR unit was expressed as the enzyme
222 amount required for the conversion of 1 mmol of NO_3^- to NO_2^- per hour and the

223 enzyme amount required for the conversion of 1 mmol of NO_3^- to NH_4^+ min^{-1} ,
224 respectively. GS activity was measured according to the methods of O'Neal and Joy
225 (1973). One unit of GS was expressed as the enzyme amount required to catalyse the
226 formation of 1 mmol of glutamylmonohydroxamate per min. The results were
227 expressed as μmol NADH used per minute per milligram of Pro. The GOGAT activity
228 was measured based on the conversion of 2-ketoglutarate to glutamate, following the
229 methods of Groat and Vance (1981). One unit of GOGAT was expressed as the
230 number of enzymes catalysing the oxidation of 1 mmol of NADH per min. The
231 deaminating GDH activity (NAD-GDH) and aminating GDH activity (NADH-GDH)
232 were determined by recording the reduction of NAD and the oxidation of NADH,
233 respectively, as described by Groat and Vance (1981). One unit of GDH was
234 calculated in units of mmol of NADH oxidized/NAD reduced per minute. Isocitrate
235 dehydrogenase (ICDH) was assayed according to the method of Lòpez-Millàn *et al.*
236 (2000). The activity was expressed as U per minute per milligram of protein.

237 **Activity of AlaAT and AspAT**

238 The AlaAT and AspAT activities were determined according to the methods of
239 Jia *et al.* (2015). Enzyme activity was expressed as $\mu\text{mol g}^{-1}\text{min}^{-1}$.

240 **Contents of free amino acids and soluble proteins and protease activity**

241 The free amino acid contents were assayed with the ninhydrin reagent method
242 according to Yemm and Cocking (1955), followed by absorbance readings at 570 nm
243 using glycine as the standard. The soluble protein contents were determined using the
244 Coomassie Brilliant Blue G-250 reagent following the description of Bradford (1976),
245 followed by absorbance readings at 595 nm using bovine serum albumin as the
246 standard. Protease activity was determined by the casein digestion assay described by
247 Drapeau (1974). By this method, one unit is the number of enzymes required to
248 release acid-soluble fragments equivalent to 0.001 A280 per minute at 37°C and pH
249 7.8.

250 **Statistical analysis**

251 The data were analysed using SPSS 17.0 and all the values are presented as the mean
252 \pm SE. The means were separated using the least significant difference (LSD) test at
253 the 5% probability level.

254 **Results**

255 **Yield**

256 Drought stress significantly inhibited the maize yield (Fig. 5). Compared with
257 the well-watered treatment, in the drought treatment, the grain number decreased by
258 29.23% in 2016 and 33.24% in 2017, and the grain yield decreased by 34.06% in
259 2016 and by 38.22% in 2017. However, the decrease in maize yield was partially
260 recovered by DCPTA. Compared with the well-watered treatment, in the
261 drought+DCPTA treatment, the grain number decreased by 14.01% in 2016 and by
262 16.55% in 2017, and the grain yield decreased by 17.98% in 2016 and by 20.54% in
263 2017. Moreover, the application of DCPTA improved maize yield under well-watered
264 conditions. Compared with the well-watered treatment, in the DCPTA treatment, the
265 grain number increased by 5.97% in 2016 and by 6.50% in 2017, and the grain yield
266 increased by 7.31% in 2016 and by 8.02% in 2017.

267 **Relative growth rate (RGR) of shoot and root**

268 The shoot growth rate was inhibited during the drought period, the root growth
269 rate was promoted over days 0-10 and subsequently decreased, and the growth rates
270 of shoots and roots recovered during rehydration (Fig. 6 and 7). In the drought
271 treatment compared with the control in 2016, the RGR of shoots and roots decreased
272 by 52.26% and by 48.59%, respectively, between day 15 and 20 and by 39.76% and
273 37.70%, respectively, between day 25 and 30 in 2016. In the drought treatment
274 compared with the control in 2017, the RGR of shoots and roots decreased by 65.18%
275 and 66.52%, respectively, between day 15 and 20 and by 51.97% and 43.74%,
276 respectively, between day 25 and 30 in 2017. However, the decrease in growth was

277 partially recovered by DCPTA. In the drought+DCPTA treatment compared with the
278 control in 2016, the RGR of shoots and roots decreased by 29.96% and 26.31%,
279 respectively, between day 15 and 20, and by 10.11% and 11.49%, respectively,
280 between day 25 and 30. In the drought+DCPTA treatment compared with the control
281 in 2017, the RGR of shoots and roots decreased by 34.20% and 42.23%, respectively,
282 between day 15 and 20, and by 12.41% and 14.75%, respectively, between day 25 and
283 30. Moreover, the application of DCPTA improved maize growth under well-watered
284 conditions. The shoot RGR difference between the well-watered+DCPTA treatment
285 and well-watered treatment was significant at days 16-20 and 26-30 in 2016 and days
286 11-30 in 2017, respectively. Similarly, the root RGR difference between the DCPTA
287 treatment and well-watered treatment was significant at days 6-10 and 16-25 in 2016
288 and days 11-30 in 2017, respectively.

289 **Root length density (RLD) and root surface area density (RSD)**

290 Drought dramatically inhibited RLD and RSD in the 0–60 cm soil profile in
291 2016 and 2017 (Fig. 8). At day 20, there was a significant difference in RLD for the
292 drought treatment and drought+DCPTA treatment in 20–40 cm in 2016 and in 20–50
293 cm in 2017, respectively. On day 30, the RLD declines were partially reversed by
294 rehydration. On day 30, there was a significant difference in RLD for the drought
295 treatment and drought+DCPTA treatment in 0–50 cm in both 2016 and 2017. On day
296 30, there was a significant ($P > 0.05$) difference in RLD for the well-watered
297 treatment and well-watered+DCPTA treatment in 0–20 cm in both 2016 and 2017. On
298 day 20, there was a significant difference in RLD between the drought treatment and
299 drought+DCPTA treatment in 10–40 cm in 2016 and 10–50 cm in 2017. On day 30,
300 the declines in RLD were partially reversed by rehydration. At day 30, there was a
301 significant ($P > 0.05$) difference in RLD between the drought treatment and
302 drought+DCPTA treatment in 0–40 cm in 2016 and 0–50 cm in 2017. On day 30,
303 there was a significant difference between RLD for the well-watered treatment and
304 well-watered+DCPTA treatment in 0–20 cm in 2016 and in 0–30 cm in 2017.

305 **Root hydraulic conductivity, flow rate of root-bleeding sap and NO₃⁻ delivery**
306 **rates**

307 The root hydraulic conductivity, flow rate of root-bleeding sap and NO₃⁻
308 concentrations in the root-bleeding sap declined continuously during the drought
309 period and recovered during rehydration (Fig. 9). In the drought treatment compared
310 with the control, the root hydraulic conductivity, flow rate of root-bleeding sap and
311 NO₃⁻ delivery rates decreased by 34.21%, 75.69% and 76.58%, respectively, on day
312 20 and by 19.34%, 35.96% and 57.37%, respectively, on day 30 in 2016; these values
313 decreased by 47.01%, 78.80% and 61.34%, respectively, on day 20 and by 29.03%,
314 33.79%, and 50.47%, respectively, on day 30 in 2017. However, the DCPTA
315 application partially reversed the decline in root hydraulic conductivity, root-bleeding
316 sap flow and NO₃⁻ delivery rates caused by drought and resulted in a faster recovery
317 after rehydration. In the drought+DCPTA treatment compared with the control, the
318 root hydraulic conductivity, root-bleeding sap flow and NO₃⁻ delivery rates decreased
319 by 17.91%, 46.73% and 41.90%, respectively, on day 20 and by 9.87%, 18.80% and
320 23.51%, respectively, on day 30 in 2016; these values decreased by 26.60%, 47.66%
321 and 37.06%, respectively, on day 20 and by 16.94%, 14.68% and 25.23%,
322 respectively, on day 30.

323 Under well-watered conditions, DCPTA significantly increased root hydraulic
324 conductivity on the 15th, 20th, 25th and 30th days in 2016 and on the 20th and 25th days
325 in 2017; DCPTA significantly increased the flow rate of root-bleeding sap on the 10th,
326 15th, 20th and 25th days in both 2016 and 2017; DCPTA significantly increased the
327 NO₃⁻ concentration in root-bleeding sap on the 10th, 15th, 20th, 25th and 30th days in
328 2016 and on the 10th, 15th, 20th and 25th days in 2017.

329 **Leaf water status (RLWC)**

330 The RLWC declined continuously over the drought period and recovered
331 during rehydration (Fig. 10). In the drought treatment compared with the control,
332 RLWC decreased by 30.88% on day 20 and by 13.08% on day 30 in 2016 and

333 decreased by 37.48% on day 20 and by 21.89% on day 30 in 2017. However, the
334 DCPTA application partially reversed the decline in RLWC caused by drought and
335 resulted in a faster recovery of the foliar RLWC contents after rehydration. In the
336 drought+DCPTA treatment compared with the control, the RLWC decreased by 11.75%
337 on day 20 and by 3.84% on day 30 in 2016 and decreased by 21.15% on day 20 and
338 by 10.73% on day 30 in 2017. Under well-watered conditions, DCPTA application
339 had no significant effect on the RLWC.

340 **Gas exchange parameters**

341 Pn, Gs and Tr declined continuously over the drought period and recovered
342 during rehydration (Fig. 11). In the drought treatment compared with the control, Pn,
343 Gs and Tr decreased by 46.20%, 68.97% and 51.35%, respectively, on day 20 and by
344 35.06%, 46.30% and 38.17%, respectively, on day 30 in 2016 and decreased by
345 56.00%, 71.10% and 62.10%, respectively, on day 20 and by 45.89%, 44.02% and
346 43.79%, respectively, on day 30 in 2017. However, the DCPTA application partially
347 reversed the decline in Pn, Gs and Tr caused by drought and resulted in a faster
348 recovery of Pn, Gs and Tr rehydration. In the drought+DCPTA treatment compared
349 with the control, Pn, Gs and Tr decreased by 23.41%, 37.39% and 20.95%,
350 respectively, on day 20 and by 8.77%, 20.89% and 10.61%, respectively, on day 30 in
351 2016 and decreased by 35.31%, 32.03% and 34.11%, respectively, on day 20 and by
352 14.16%, 15.33% and 8.62%, respectively, on day 30. Under well-watered conditions,
353 DCPTA significantly increased Pn on the 10th, 15th, 25th and 30th days in 2016 and on
354 the 15th, 20th and 25th days in 2017. In addition, under well-watered conditions,
355 DCPTA significantly increased Gs on the 15th, 20th, 25th and 30th days in 2016 and on
356 the 10th, 15th, 20th, 25th and 30th days in 2017 and significantly increased Tr on the 10th,
357 15th, 20th, 25th and 30th days in both 2016 and 2017.

358 In 2016 and 2017, Ci showed the same variation tendency during the drought
359 period. In the drought treatment, Ci declined over days 0-10, subsequently increased
360 over days 10-20, and then decreased after rehydration. In the drought+DCPTA

361 treatment, Ci declined over days 0-15 day and subsequently increased over days
362 15-30. Under well-watered conditions, DCPTA application had no significant effect
363 on Ci.

364 **Chloroplast ultrastructure**

365 Regardless of whether DCPTA was applied, the photosynthetic mesophyll cells
366 of the non-stressed seedlings included a delimited cell wall containing chloroplasts.
367 These chloroplasts had intact membranes and a regular arrangement of granal and
368 stromal thylakoids, which were attached to the cell wall and exhibited typical
369 ellipsoidal shapes (Fig. 12). However, in the stressed seedlings, the cell wall structure
370 was incomplete and exhibited indistinct gradation, a lower density, and loose edges.
371 Plasmolysis and degradation were also evident in part of the cell membrane.
372 Moreover, the chloroplasts, which separated from the plasma membrane, were nearly
373 round and swelled asymmetrically, the thylakoids were overly disorganized, and the
374 thylakoid membranes were loose and showed an increased number of plastoglobules.
375 In the PEG-6000+DCPTA treatment, the complete membrane structures of the
376 chloroplasts were present, and the shapes of the chloroplasts changed slightly from
377 elongated ellipses to ellipses close to the cell walls. A well-aligned internal lamellar
378 system and fewer plastoglobules were observed in the leaves of the
379 PEG-6000+DCPTA treatment compared with the leaves of the PEG-6000 treatment.

380 **ICDH activity**

381 ICDH activity declined continuously over the drought period and recovered
382 during rehydration (Fig. 13). In the drought treatment compared with the control,
383 ICDH activity decreased by 40.75% on day 20 and by 36.33% on day 30 in 2016 and
384 decreased by 37.77% on day 20 and by 33.07% on day 30 in 2017. However, the
385 DCPTA application partially reversed the decline in ICDH activity caused by drought
386 and resulted in a faster recovery of ICDH activity after rehydration. In the
387 drought+DCPTA treatment compared with the control, ICDH decreased by 24.92% on

388 day 20 and by 19.94% on day 30 in 2016 and decreased by 19.88% on day 20 and by
389 13.63% on day 30 in 2017. Under well-watered conditions, the application of DCPTA
390 significantly increased the foliar ICDH activity on the 10th, 15th, 20th and 25th days in
391 2016 and on the 15th, 20th, and 25th days in 2017.

392 **Contents of NO₃⁻, NO₂⁻ and NH₄⁺**

393 The foliar NO₃⁻ and NO₂⁻ contents declined continuously during the drought
394 period and recovered during rehydration (Fig. 14). In the drought treatment compared
395 with the control, the foliar NO₃⁻ and NO₂⁻ contents decreased by 39.82% and 38.27%,
396 respectively, on day 20 and by 33.62% and 35.11%, respectively, on day 30 in 2016
397 and decreased by 57.97% and 32.27%, respectively, on day 20 and by 42.38% and
398 25.21%, respectively, on day 30 in 2017. However, the DCPTA application partially
399 reversed the decline in the foliar NO₃⁻ and NO₂⁻ contents caused by drought and
400 resulted in a faster recovery of the foliar NO₃⁻ and NO₂⁻ contents after rehydration. In
401 the drought+DCPTA treatment compared with the control, the foliar NO₃⁻ and NO₂⁻
402 contents decreased by 25.94% and 23.31%, respectively, on day 20 and by 14.25%
403 and 18.55%, respectively, on day 30 in 2016 and decreased by 33.86% and 18.26%,
404 respectively, on day 20 and by 17.26% and 8.60%, respectively, on day 30 in 2017. In
405 contrast, drought led to a marked elevation in the foliar NH₄⁺ content. In the drought
406 treatment compared with the control, the foliar NH₄⁺ increased by 52.48% on day 20
407 and by 29.18% on day 30 in 2016 and increased by 98.68% on day 20 and by 72.21%
408 on day 30 in 2017. In contrast, the DCPTA application suppressed the increase in the
409 foliar NH₄⁺ content induced by drought. In the drought+DCPTA treatment compared
410 with the control, the foliar NH₄⁺ increased by 20.83% on day 20 and by 13.33% on
411 day 30 in 2016 and increased by 45.37% on day 20 and by 33.29% on day 30 in 2017.

412 Under well-watered conditions, DCPTA significantly increased the foliar NO₃⁻
413 content on the 20th and 25th days in 2016 and on the 15th, 20th, 25th and 30th days in
414 2017. However, the DCPTA application had no significant effect on the foliar
415 contents of NO₂⁻ and NH₄⁺.

416 **Activities of NR and NiR**

417 The activities of foliar NR and NiR declined continuously during the drought
418 period and recovered during rehydration (Fig. 15). In the drought treatment compared
419 with the control treatment, the activities of foliar NR and NiR decreased by 40.37%
420 and 36.91%, respectively, on day 20 and by 34.42% and 29.82%, respectively, on day
421 30 in 2016 and decreased by 52.80% and 32.46%, respectively, on day 20 and by
422 37.36% and 21.28%, respectively, on day 30 in 2017. However, the DCPTA
423 application partially reversed the declines in the activities of foliar NR and NiR
424 caused by drought and resulted in a faster recovery of the foliar NR and NiR activities
425 after rehydration. In the drought+DCPTA treatment compared with the control, the
426 activities of foliar NR and NiR decreased by 15.54% and 14.21%, respectively, on
427 day 20 and by 10.79% and 7.79%, respectively, on day 30 in 2016 and decreased by
428 25.10% and 12.39%, respectively, on day 20 and by 13.55% and 4.96%, respectively,
429 on day 30 in 2017. Under well-watered conditions, DCPTA significantly increased
430 the foliar NR activity on the 10th, 15th and 25th days in 2016 and on the 10th, 15th, 20th
431 and 25th days in 2017. Similarly, under well-watered conditions, DCPTA significantly
432 increased the foliar NiR activity on the 10th and 25th days in 2016 and on the 15th and
433 20th days in 2017.

434 **Activities of GS, GOGAT and GDH**

435 The activities of foliar GS and GOGAT first increased and then decreased
436 during the drought period and recovered during rehydration (Fig. 16). In the drought
437 treatment compared with the control, the activities of foliar GS and GOGAT
438 decreased by 40.69% and 60.62%, respectively, on day 20 and by 33.65% and 51.39%,
439 respectively, on day 30 in 2016 and decreased by 47.57% and 66.84%, respectively,
440 on day 20 and by 37.96% and 56.77%, respectively, on day 30 in 2017. However, the
441 DCPTA application partially reversed the decline in the foliar GS and GOGAT
442 activities caused by drought and resulted in a faster recovery of the foliar GS and
443 GOGAT activities after rehydration. In the drought+DCPTA treatment compared with

444 the control, the foliar GS and GOGAT activities decreased by 19.87% and 33.37%,
445 respectively, on day 20 and by 10.99% and 15.17%, respectively, on day 30 in 2016
446 and decreased by 23.56% and 33.02%, respectively, on day 20 and by 14.93% and
447 18.20%, respectively, on day 30 in 2017. Likewise, the DCPTA application alone
448 caused an increase in the foliar GS and GOGAT activities. In contrast, drought led to
449 marked increases in the activities of foliar NAD-GDH and NADH-GDH. In the
450 drought treatment compared with the control, the activities of foliar NAD-GDH and
451 NADH-GDH increased by 87.16% and 150.92%, respectively, on day 20 and by
452 84.01% and 134.71%, respectively, on day 30 in 2016 and increased by 103.99% and
453 137.36%, respectively, on day 20 and by 96.13% and 111.20%, respectively, on day
454 30 in 2017. However, the DCPTA application partially reversed the increases in the
455 activities of foliar NAD-GDH and NADH-GDH caused by drought and resulted in a
456 faster recovery of the foliar NAD-GDH and NADH-GDH activities after rehydration.
457 In the drought+DCPTA treatment compared with the control, the activities of foliar
458 NAD-GDH and NADH-GDH increased by 49.55% and 92.59%, respectively, on day
459 20 and by 36.52% and 49.51%, respectively, on day 30 in 2016 and increased by
460 46.90% and 80.94%, respectively, on day 20 and by 35.43% and 45.60%, respectively,
461 on day 30 in 2017.

462 Under well-watered conditions, DCPTA significantly increased the foliar GS
463 activity on the 20th and 25th days in 2016 and on the 10th 20th and 25th days in 2017.
464 Similarly, under well-watered conditions, DCPTA significantly increased the foliar
465 GOGAT activity on day 15 in 2017 and significantly increased the foliar NAD-GDH
466 activity on day 15 in 2016

467 **Activities of AlaAT and AspAT**

468 The activities of foliar AlaAT and AspAT first increased and then continuously
469 decreased during the drought period and recovered during rehydration (Fig. 17). In the
470 drought treatment compared with the control, the activities of foliar AlaAT and AspAT
471 decreased by 44.18% and 65.51%, respectively, on day 20 and by 36.43% and 38.52%,

472 respectively, on day 30 in 2016 and decreased by 56.80% and 54.92%, respectively,
473 on day 20 and by 41.43% and 41.29%, respectively, on day 30 in 2017. However, the
474 DCPTA application partially reversed the decline in the activities of foliar AlaAT and
475 AspAT caused by drought and resulted in a faster recovery of the foliar AlaAT and
476 AspAT activities after rehydration. In the drought+DCPTA treatment compared with
477 the control, the activities of foliar AlaAT and AspAT decreased by 17.45% and
478 35.39%, respectively, on day 20 and by 15.84% and 17.17%, respectively, on day 30
479 in 2016 and decreased by 32.49% and 37.82%, respectively, on day 20 and by 17.46%
480 and 18.21%, respectively, on day 30 in 2017.

481 Under well-watered conditions, DCPTA significantly increased the foliar
482 AlaAT activity on the 10th, 15th, and 20th days in 2016 and on the 10th, 15th, 20th and
483 25th days in 2017. Similarly, under well-watered conditions, DCPTA significantly
484 increased the foliar AspAT activity on day 15 in 2016 and on the 5th, 10th, 15th and 25th
485 days in 2017.

486 **Protease activity and contents of proteins and free amino acids**

487 The protease activity and free amino acid contents increased continuously
488 during the drought period and decreased during rehydration (Fig. 18). In the drought
489 treatment compared with the control, the protease activity and free amino acid
490 contents increased by 122.48% and 88.92%, respectively, on day 20 and by 55.03%
491 and 34.51%, respectively, on day 30 in 2016 and increased by 145.15% and 78.58%,
492 respectively, on day 20 and by 57.08% and 43.29%, respectively, on day 30 in 2017.
493 However, the DCPTA application partially reversed the increases in the protease
494 activity and free amino acid contents caused by drought.

495 In the drought+DCPTA treatment compared with the control, the protease
496 activity and free amino acid contents increased by 78.47% and 24.77%, respectively,
497 on day 20 and by 16.46% and 6.62%, respectively, on day 30 in 2016 and increased
498 by 65.41% and 30.24%, respectively, on day 20 and 14.50% and 13.57%, respectively,
499 on day 30 in 2017.

500 In contrast, drought led to a marked decrease in the foliar protein content. In the
501 drought treatment compared with the control, the foliar protein content decreased by
502 35.51% on day 20 and by 18.32% on day 30 in 2016 and decreased by 44.81% on day
503 20 and by 22.50% on day 30 in 2017. In contrast, the DCPTA application suppressed
504 the increase in the foliar protein content induced by drought. In the drought+DCPTA
505 treatment compared with the control, the foliar protein content increased by 19.54%
506 on day 20 and by 7.25% on day 30 in 2016 and increased by 25.46% on day 20 and
507 by 10.30% on day 30 in 2017.

508 Significant differences between the foliar protein contents of the well-watered
509 treatment and well-watered+DCPTA treatment were observed on day 10 in 2017 and
510 on day 15 in 2017, and significant differences between the free amino acid contents of
511 these treatments were observed on day 10 in 2017.

512 **Discussion**

513 One of the most clear and consistent effects of drought on crops is the inhibition
514 of growth and yield (Sinclair, 2011). In this experiment, exogenous DCPTA partly
515 mitigated the reductions in plant growth and yield induced by drought, as expressed
516 by the stable root and root RGR, GN and GY (Fig. 5, Fig. 6 and Fig. 7). Moreover,
517 exogenous DCPTA promoted growth and yield under well-watered conditions.

518 N is a necessary macro-nutrient element for plants and a main limiting factor in
519 plant growth and development (Kusano *et al.*, 2011). The pre-female inflorescence
520 emergence stage is the important stage determining maize yield (Talaat *et al.*, 2015).
521 The inhibition of maize growth induced by drought could be partly attributed to
522 nitrogen metabolism during the pre-female inflorescence emergence stage. NO_3^- is
523 the main nitrogen source assimilated by higher plants in agricultural soils (Robredo *et al.*
524 *et al.*, 2011). Similar to previous reports for tomato (Sánchez-Rodríguez *et al.*, 2011) and
525 wheat (Fresneau *et al.*, 2007), drought significantly diminished the NO_3^- content in
526 maize leaves in both the DCPTA-treated and non-treated leaves (Fig. 14). This
527 decrease may be explained by drought-induced inhibitions in nitrate uptake from the

528 roots and/or nitrate transport. However, the reduction in the non-treated leaves was
529 greater than that in the DCPTA-treated leaves in this study.

530 Maintaining the supply of nutrients and water from the soil to crop depends on
531 root morphology, which can be characterized by RLD and RSD (Kamran *et al.*, 2018).
532 Previous studies have reported that DCPTA promotes root development in tomatoes
533 (Keithly *et al.*, 1990a). In this study, there was a significant difference between the
534 RLD and RSD of the well-watered treatment and DCPTA treatment in 0–20 cm and
535 0–30 cm in 2016 and 2017 on day 30 (Fig. 8). This result suggests that DCPTA
536 promoted root development in maize under well-watered conditions. Interestingly,
537 under drought conditions, the DCPTA application significantly increased RLD, RSD
538 and the root RGR. These results indicate that the DCPTA application also promoted
539 maize root growth and improved the spatial and temporal distribution of roots, which
540 was beneficial to NO_3^- uptake under drought conditions.

541 The xylem sap transports water and nutrients from the roots throughout the plant
542 and depends on transpiration intensity and root pressure. The increased root hydraulic
543 conductivity and flow rate of root-bleeding sap induced by the DCPTA application
544 may, due to the enhanced root pressure, which depend on physiological activity of the
545 whole root system (Fig. 9) (Noguchi *et al.*, 2005; Lui *et al.*, 2014). In addition, the
546 NO_3^- delivery rate in the presence of DCPTA was significantly higher than that
547 without DCPTA under drought conditions, which may partly result from the improved
548 NO_3^- absorption and enhanced root pressure induced by DCPTA. The stable RLWC
549 in the drought+DCPTA treatment suggests an abundant supply water to the
550 aboveground parts, and balanced transpirational loss and water uptake under drought
551 conditions; as a result, the DCPTA-treated plants maintained G_s , which reduced the
552 leaf epidermal resistance and promoted the mass flow of water to the leaf surface and
553 the transportation of the NO_3^- required for N metabolism in leaves (Fig. 10 and Fig.
554 11). Under drought conditions, increases in the foliar NO_3^- were observed in the
555 DCPTA-treated plants (Fig. 14).

556 Whether stomatal or non-stomatal factors are the main cause of a reduced P_n

557 may be determined by changes in G_s and C_i (Bethke and Drew, 1992). During the
558 early period of drought, the change of C_i were accompanied by continuously declined
559 G_s , then G_s decreases but C_i shows an increase (Fig. 11).
560 Thus, the decrease of the P_n in drought-treated plants was mainly attributed to
561 stomatal limitations firstly, and then, non-stomatal limitations induced by the damage
562 of photochemical mechanism, partly reflected by damaged chloroplast (Fig. 12).
563 However, DCPTA application maintains relatively high G_s , ensuring the availability
564 of CO_2 for the carbon reduction cycle. Simultaneously, the DCPTA application
565 delayed the increase in C_i and protected the chloroplast ultrastructure against
566 drought-induced oxidative damage, which suggests that DCPTA can protect the
567 photochemical mechanism and, as a result, ensures a more efficient photosynthesis
568 process after rehydration. Moreover, similar to previous studies on spruce (Keithly *et*
569 *al.*, 1990a), sugar beets (Keithly *et al.*, 1990b) and guayule (Wan and Mendoza, 1992),
570 DCPTA application also promoted photosynthesis under well-watered conditions.

571 In most plants, nitrate reduction occurs in leaves. NO_3^- , after being taken up into
572 the leaf cell, is converted to NH_4^+ by two successive steps catalysed by NR and NiR.
573 NR, the rate-limiting enzyme of nitrogen assimilation, is highly sensitive to stress
574 (Plett *et al.*, 2016). Similar to previous studies on wheat and barley, the NR activity
575 continuously declined in response to drought (Fig. 15) (Robredo *et al.*, 2011;
576 Fresneau *et al.*, 2007). As a typical nitrate-induced enzyme, NR activity is primarily
577 regulated by the NO_3^- concentration in the leaves (Chamizo-Ampudia *et al.*, 2017).
578 The up-regulation of foliar NR activity in the drought+DCPTA treatment may result
579 from the increase in the foliar NO_3^- content (Fig. 14). Moreover, the reduction in the
580 foliar NiR activity under drought conditions was significantly reversed by the
581 application of DCPTA, which may be because the DCPTA-stabilized photosynthesis
582 resulted in a sufficient supply of Fd_{red} (Fig. 11 and Fig. 15), thus promoting the
583 conversion of NO_2^- to NH_4^+ . The present results indicate that DCPTA pretreatment
584 could maintain a high NO_3^- assimilation ability in maize under drought conditions.

585 Although the foliar NR and NiR activities declined during the drought period, the

586 foliar NH_4^+ content exhibited an increasing tendency in our experiment (Fig. 14). This
587 increase may be associated with the glycine oxidation in activated photorespiration,
588 which is induced by decreases in C_i levels under drought conditions (Wang *et al.*,
589 2012). The increased G_s induced by DCPTA was beneficial to the increase in CO_2 in
590 the cellular spaces of the leaf, implying that photorespiration was partly alleviated
591 (Fig. 11).

592 In plants cells, excessive levels of NH_4^+ are destructive, and the major NH_4^+
593 assimilation pathway is the GS/GOGAT cycle in higher plants. When the
594 GS/GOGAT cycle is suppressed and the NH_4^+ content rises continuously under
595 stress, NH_4^+ could serve as a substrate to form glutamate via the reversible amination
596 of 2-OG by GDH catalyse, although the enzyme has a lower affinity for NH_4^+
597 (Fontaine *et al.*, 2012). In general, drought inhibited NH_4^+ assimilation (Naya *et al.*,
598 2007). During the early period of drought, GDH activity increased sharply, GS
599 activity increased slightly, and GOGAT remained stable (Fig. 16). These results
600 suggest that accelerated NH_4^+ assimilation in maize may be an adaptive mechanism
601 to produce more glutamate and eliminate the accumulation of excess foliar NH_4^+ .
602 Subsequently, the GS and GOGAT activities decreased, which may have resulted
603 from an inadequate supply of energy and 2-OG because of photosynthetic inhibition
604 and decreased ICDH activity (Fig. 13). GDH activity decreased with drought, which
605 may be due to the oxidative degradation of GS caused by the overproduction of
606 reactive oxygen species (ROS) induced by drought conditions (Xia *et al.*, 2015).

607 The DCPTA application altered the major NH_4^+ assimilation pathway,
608 maintained the GOGAT/GS cycle and suppressed the GDH pathway, which may
609 have contributed to maintaining the conversion of NH_4^+ to glutamine and the
610 subsequent formation of glutamate from glutamine. This result may occur because
611 the photosynthetic stability and ICDH activity induced by the DCPTA application
612 promoted 2-OG synthesis and the reducing power (i.e., NADPH, ATP, or Fd_{red}) in
613 plants during the drought period, thus providing the GS/GOGAT cycle with
614 relatively sufficient substrates and energy and favouring the enhancement of foliar

615 GOGAT and GS activities (Du *et al.*, 2016). As a result, with the application of
616 DCPTA, drought had less of an effect on the activities of GS and GOGAT.

617 Although DCPTA promoted NO_3^- assimilation, as expressed by the increased NR
618 and NiR activities (Fig. 15), this treatment compared to the drought treatment caused
619 significant decreases in the NH_4^+ content, which means that exogenous DCPTA
620 resulted in the integration of NH_4^+ into the structure of organic compounds, thereby
621 contributing to the reduction in the NH_4^+ content. Therefore, the DCPTA application
622 effectively modulated the activities of ICDH, GS, GOGAT and GDH and accelerated
623 the conversion of NH_4^+ to glutamate, which is the precursor of other amino acids.

624 Transamination is a key step in the biosynthesis of various amino acids from
625 glutamate, with the availability of C skeletons from the Krebs cycle (Hodges, 2002).
626 In our studies, both the aminotransferases studied, AlaAT and AspAT, showed
627 increased activity in maize during the early drought period (Fig. 17). Such increases
628 in aminotransferases activities under drought conditions might help in the synthesis of
629 increased amounts of amino acids that act as compatible cytoplasmic solutes and
630 protect cell organelles and biomolecules, thus reducing the adverse effects of drought
631 on maize (Munns and Tester, 2008). Subsequently, the AlaAT and AspAT activities
632 decreased, which may be attributable to the weakened GS/NADH-GOGAT pathway
633 (Fig. 16) (Gangwar and Singh, 2011). Moreover, stable aminotransferase activities
634 were observed in DCPTA-treated plants. This finding may be associated with
635 increased GS/GOGAT activities, which can generate more glutamate to serve as a
636 substrate for transamination reactions in maize treated with DCPTA under drought
637 conditions.

638 Most soluble proteins are enzymes that participate in various metabolic
639 pathways in plants; therefore, the soluble protein content is considered one of the
640 most important indices reflecting the overall metabolic level in plants. Protein
641 synthesis in plants is very sensitive to abiotic stresses and is positively correlated with
642 stress tolerance (Fresneau *et al.*, 2007). Free amino acids are the building blocks of
643 proteins. Drought increased the free amino acid contents, which may mainly be

644 attributed to the increased AlaAT and AspAT activities in the early drought period
645 and the subsequent promotion of protein degradation (Fig. 18) (Yang *et al.*, 2013).
646 However, DCPTA-treated seedlings maintained higher soluble protein levels and
647 lower free amino acid levels than did non-DCPTA-treated seedlings in response to
648 drought. This result may occur because DCPTA inhibited protein degradation by
649 stable protease activities and maintained protein stability, ensuring the series of
650 physiological and biochemical processes that occur normally under stress conditions.
651 Additionally, the DCPTA application increased the amino acid contents under
652 well-watered conditions, which may be attributable to the promoted biosynthesis and
653 accumulation of amino acids, which ultimately improved plant growth and
654 development (Talaat and Shawky, 2016).

655 **Conclusions**

656 The present study suggested that DCPTA treatment increased NO_3^- uptake and
657 the long-distance transportation of NO_3^- from the roots to the leaves via the
658 production of excess roots and maintained a stabilized transpiration rate. The
659 increased foliar NO_3^- content up-regulated NR activity and maintained a high N
660 assimilation ability that was restrained by drought. Exogenous DCPTA effectively
661 regulated the ICDH, GS, GOGAT and GDH activities to speed up the conversion of
662 NH_4^+ to Glu, reduced the toxicity of excess NH_4^+ to the plant, and accelerated the
663 synthesis of proteins and amino acids. Moreover, DCPTA treatment maintained
664 increased the photosynthetic capacity, supply nitrogen metabolism of energy and
665 carbon skeleton thus alleviating the inhibition of growth by drought in maize.

918 significantly different at $P < 0.05$ (LSD test).

919 **Fig. 8** Effect of drought and/or DCPTA treatment on root length density (RLD) and
920 root surface area density (RSD) for different soil depths on the 20th day and 30th day
921 after treatment in 2016 and 2017.

922 **Fig. 9** Effect of drought and/or DCPTA treatment on root hydraulic conductivity, the
923 flow rate of root-bleeding sap and the NO_3^- delivery rate in 2016 and 2017. The data
924 represent the means of independent measurements with five replicates, and the
925 standard deviations are indicated by the vertical error bars. Values with the same

926 letters on the bars are not significantly different at $P < 0.05$ (LSD test).

927 **Fig. 10** Effect of drought and/or DCPTA treatment on relative water content of the
928 leaves (RLWC) in 2016 and 2017. The data represent the means of independent
929 measurements with five replicates, and the standard deviations are indicated by the
930 vertical error bars. Values with the same letters on the bars are not significantly
931 different at $P < 0.05$ (LSD test).

932 **Fig. 11** Effect of drought and/or DCPTA treatment on the gas exchange parameters in
933 the maize leaves in 2016 and 2017. Pn, net photosynthetic rate; Gs, stomatal
934 conductance; Tr, transpiration rate; Ci, intercellular CO₂ concentration. The data
935 represent the means of independent measurements with five replicates, and the
936 standard deviations are indicated by the vertical error bars. Values with the same
937 letters on the bars are not significantly different at $P < 0.05$ (LSD test).

938 **Fig. 12** Ultrastructure of the photosynthetic apparatus in the maize leaves after 20
939 days of treatment with drought and/or DCPTA in 2016 and 2017. SL, stroma lamella;
940 GL, grana lamellae; CW, cell wall; and P, plastoglobule. The scale bars for the
941 photosynthetic apparatus represent 2000 nm.

942 **Fig. 13** Effects of drought and/or DCPTA treatment on isocitrate dehydrogenase
943 (ICDH) activity in 2016 and 2017. The data represent the means of independent
944 measurements with five replicates, and the standard deviations are indicated by the
945 vertical error bars. Values with the same letters on the bars are not significantly
946 different at $P < 0.05$ (LSD test).

947 **Fig. 14** Effects of drought and/or DCPTA treatment on the nitrate (NO₃⁻), nitrite
948 (NO₂⁻) and ammonium (NH₄⁺) contents in the leaves of maize in 2016 and 2017. The
949 data represent the means of independent measurements with five replicates, and the
950 standard deviations are indicated by the vertical error bars. Values with the same
951 letters on the bars are not significantly different at $P < 0.05$ (LSD test).

952 **Fig. 15** Effects of drought and/or DCPTA treatment on nitrate reductase (NR) and
953 nitrite reductase (NiR) activities in the leaves of maize in 2016 and 2017. The data
954 represent the means of independent measurements with five replicates, and the

955 standard deviations are indicated by the vertical error bars. Values with the same
956 letters on the bars are not significantly different at $P < 0.05$ (LSD test).

957 **Fig. 16** Effects of drought and/or DCPTA treatment on the glutamine synthetase (GS),
958 glutamate synthase (GOGAT) and glutamate dehydrogenase (GDH) activities in the
959 leaves of maize in 2016 and 2017. The data represent the means of independent
960 measurements with five replicates, and the standard deviations are indicated by the
961 vertical error bars. Values with the same letters on the bars are not significantly
962 different at $P < 0.05$ (LSD test).

963 **Fig. 17** Effects of drought and/or DCPTA treatment on the alanine aminotransferase
964 (AlaAT) and aspartate aminotransferase (AspAT) activities in the leaves of maize in
965 2016 and 2017. The data represent the means of independent measurements with five
966 replicates, and the standard deviations are indicated by the vertical error bars. Values
967 with the same letters on the bars are not significantly different at $P < 0.05$ (LSD test).

968 **Fig. 18** Effects of drought and/or DCPTA treatment on the protease activity and
969 protein and free amino acid contents in the leaves of maize in 2016 and 2017. The
970 data represent the means of independent measurements with five replicates, and the
971 standard deviations are indicated by the vertical error bars. Values with the same
972 letters on the bars are not significantly different at $P < 0.05$ (LSD test).
