ABSTRACT

The gastrointestinal colonizer *Enterococcus faecium* is a leading cause of hospital-acquired infections. Multidrug-resistant (MDR) *E. faecium* are particularly concerning for infection treatment. Previous comparative genomic studies revealed that subspecies referred to as Clade A and Clade B exist within *E. faecium*. MDR *E. faecium* belong to Clade A, while Clade B consists of drug-susceptible fecal commensal *E. faecium*. Isolates from Clade A are further grouped into two sub-clades, A1 and A2. In general, Clade A1 isolates are hospital epidemic isolates whereas Clade A2 isolates are isolates from animals and sporadic human infections. Such phylogenetic separation indicates that reduced gene exchange occurs between the clades. We hypothesize that endogenous barriers to gene exchange exist between *E. faecium* clades. Restriction-modification (R-M) systems are such barriers in other microbes. We utilized bioinformatics analysis coupled with second generation and third generation deep sequencing platforms to characterize the methylome of two representative *E. faecium* strains, one from Clade A1 and one from Clade B. We identified a Type I R-M system that is Clade A1-specific, is active for DNA methylation, and significantly reduces transformability of Clade A1 *E. faecium*. Based on our results, we conclude that R-M systems act as barriers to horizontal gene exchange in *E. faecium* and propose that R-M systems contribute to *E. faecium* subspecies separation.

IMPORTANCE

Enterococcus faecium is a leading cause of hospital-acquired infections around the world. Rising antibiotic resistance in certain *E. faecium* lineages leaves fewer treatment options. The overarching aim of the attached work was to determine whether restriction-modification (R-M) systems contribute to the structure of the *E. faecium* species, wherein hospital-epidemic and non-hospital-epidemic isolates have distinct evolutionary histories and highly resolved clade

34 structures. R-M provides bacteria with a type of innate immunity to horizontal gene transfer
35 (HGT). We identified a Type I R-M system that is enriched in the hospital-epidemic clade and
36 determined that it is active for DNA modification activity and significantly impacts HGT. Overall,
37 this work is important because it provides a mechanism for the observed clade structure of *E.*
38 *faecium* as well as a mechanism for facilitated gene exchange among hospital-epidemic *E.*
39 *faecium*.
40

INTRODUCTION

Enterococcus faecium is a Gram-positive opportunistic pathogen that normally resides in the gastrointestinal tracts of humans and other animals (1, 2). *E. faecium* can cause life-threatening infections such as endocarditis and is among the leading causes of catheter-associated bloodstream and urinary tract infections in clinical settings (3).

Previous comparative genomic studies revealed that subspecies exist within *E. faecium* (4-7). Different names have been used by different groups to describe these clades; in this study, we use the Clade A/B nomenclature. Generally speaking, MDR *E. faecium* belong to Clade A, while Clade B consists of drug-susceptible fecal commensal *E. faecium* (8). Clade A is further split into two subclades, A1 and A2, with hospital-endemic strains generally clustering in Clade A1 and sporadic infection isolates and animal isolates generally clustering in Clade A2 (8). Specific phenotypes and genomic features are enriched in Clade A1 isolates relative to Clade A2 and B isolates (8). Specifically, Clade A1 isolates have significantly higher mutation rates, larger overall genome sizes including a larger core genome, and possess more mobile elements. On the other hand, Clade A2 possesses a larger pan-genome than Clade A1 and B, possibly reflective of the broader host origins of these strains. Given that Clade A and Clade B strains would be expected to co-mingle in certain environments (for example, in hospital and municipal sewage), the phylogenetic separation among the *E. faecium* clades suggests that they are not sharing genetic information freely because of endogenous barriers to genetic exchange.

Horizontal gene transfer (HGT) is the exchange of genetic material between cells rather than the vertical inheritance of genetic material from a parental cell. Bacteria can encode genome defense mechanisms that can act in opposition to HGT. Two examples of these mechanisms are clustered regularly interspaced short palindromic repeats (CRISPR) and associated proteins (CRISPR-Cas) systems and restriction-modification (R-M) systems. CRISPR-Cas is a dynamic

immune system that utilizes sequence complementarity between self (CRISPR RNAs) and foreign nucleic acid to carry out its restrictive function, whereas R-M discriminates self from foreign DNA by DNA methylation patterns. If the *E. faecium* clades encode different defense mechanisms, they may not exchange genetic information freely, thereby facilitating and maintaining phylogenetic separation. However, little is known about CRISPR-Cas and R-M in *E. faecium*. Genomic analysis suggests that these systems could contribute to the observed clade structure of *E. faecium*. For example, CRISPR-Cas systems have been identified exclusively in Clade B *E. faecium* and in sporadic Clade A-Clade B recombinant strains (8). For R-M, a predicted methyl-directed restriction endonuclease (REase) is enriched in Clade A2 and B *E. faecium* genomes relative to Clade A1 genomes (8).

Here, we focused on R-M systems and their roles in regulating gene exchange in *E. faecium* because little is known about R-M defense in this species. Moreover, there is precedent in the literature for R-M systems contributing to bacterial clade structure, as has been observed in *Burkholderia* (9) and *Neisseria* (10). Our overarching hypothesis is that the *E. faecium* clades encode different R-M systems, thereby inhibiting genetic exchange between them. In general, R-M systems are composed of cognate methyltransferase (MTase) and REase activities and are classified into different types based on the specific number and types of enzymes in the system, as well as characteristics such as methylation type and pattern, cofactor requirement, and restriction activity (11). A MTase recognizes specific sequences in the bacterial genome and transfers a methyl group to either an adenine or a cytosine, resulting in 6-methyladenine (m6A), 4-methylcytosine (m4C), or 5-methylcytosine (m5C). A REase may recognize the same sequence as a MTase and cleave that region if the sequence is unmethylated (or in some cases, if methylated). With the activities of MTases and REases, bacteria can use R-M to impede entry of non-self DNA.

In this study, we used single-molecule real-time (SMRT) sequencing and whole genome bisulfite sequencing to characterize the methylomes of representative *E. faecium* strains from Clade A1 (*E. faecium* 1,231,502; or Efm502) and Clade B (*E. faecium* 1,141,733; or Efm733). Two unique m6A methylation patterns were identified, one in each strain. These patterns were asymmetric and bipartite, which is characteristic of Type I R-M methylation motifs (12). Bioinformatic analyses were performed to identify candidate genes responsible for the methylation. A unique Type I R-M system is encoded by each strain. We have named these systems Efa502I (for Efm502) and Efa733I (for Efm733). Expression of these candidate systems in *E. faecalis* heterologous hosts followed by SMRT sequencing confirmed that they are responsible for the methylation patterns observed in Efm502 and Efm733. A functional analysis was performed in order to assess the abilities of these systems to reduce *E. faecium* HGT by transformation. In a comparative analysis among 73 *E. faecium* genomes, we found that Efa502I is significantly enriched among Clade A1 isolates, while the Type I R-M system of Efm733 appears to be strain-specific. Overall, this study is a first step towards understanding the role of R-M in regulating HGT in *E. faecium* and the potential for R-M as one mechanism for the clade structure of *E. faecium*.

METHODS

Bacterial strains and growth conditions. The strains used in this study are shown in Table 1. All enterococci were grown in Brain Heart Infusion (BHI) broth or agar at 37°C, unless otherwise stated. *Escherichia coli* strains were grown in Luria Broth (LB) at 37°C and with shaking at 225 rpm unless otherwise stated. Antibiotic concentrations for enterococcal strains were as follows: rifampin, 50 µg/mL; fusidic acid, 25 µg/mL; spectinomycin, 500 µg/mL; streptomycin, 500 µg/mL; chloramphenicol, 15 µg/mL. Antibiotic concentrations for *E. coli* strains were as follows: chloramphenicol, 15 µg/mL; ampicillin, 100 µg/mL. All REases were purchased from New England Biolabs (NEB) and used per the manufacturer's instructions. PCR was performed using

Taq polymerase (NEB) or Phusion (Fisher). Sanger sequencing to validate all genetic constructs was performed at the Massachusetts General Hospital DNA Core facility (Boston, MA).

Isolation of genomic DNA. Enterococcal strains were cultured overnight in BHI broth prior to genomic DNA (gDNA) extraction. The extraction was performed using a Qiagen Blood and Tissue DNeasy Kit using a previously published protocol (13). To isolate *E. coli* gDNA, bacteria were grown overnight in LB broth prior to extraction using either the Blood and Tissue DNeasy kit (Qiagen) or the UltraClean Microbial DNA Isolation Kit (Qiagen) per the manufacturer's instructions.

SMRT sequencing and methylome detection. SMRT sequencing was performed by the Johns Hopkins Medical Institute Deep Sequencing and Microarray Core. After sequencing, the reads were assembled into contigs and analyzed using the RS modification and motif detection protocol in SMRT portal v1.3.3. An *in silico* control was used as a methylation baseline. SMRT sequencing in *E. faecalis* expressing Efa502I or Efa733I was performed by the University of Michigan sequencing core facility. Reads were mapped to the *E. faecalis* OG1RF reference sequence (GenBank accession number NC_017316), and the methylation motifs were detected using the RS modification and motif detection protocol in SMRT portal v.2.3.2.

Bioinformatic analysis of R-M systems in eight *E. faecium* genomes. The entire protein complement for eight previously sequenced *E. faecium* isolates (14) was analyzed. To identify potential MTases, the REBASE Gold Standard list (15) was used as a reference. This list is comprised of biochemically verified MTases and REases. Each protein sequence from *E. faecium* genomes was analyzed using BlastP against the REBASE Gold Standard list. The protein sequences with significant (e-value $<1e^{-3}$) homology to REBASE Gold Standard proteins

were further filtered by protein size. If an *E. faecium* query protein length was less than half of its subject's length, the match was removed from the prediction list. Due to the sequence diversity of REases which complicates their bioinformatic identification (15), guilt-by-association was used to identify full R-M systems as we have previously described (16). The proteins encoded near candidate DNA MTases were analyzed using BLAST and Pfam for conserved domains consistent with REase activities and/or sequence identity to confirmed REases. The amino acid sequence of each R-M candidate was then pairwise compared among all the eight strains to identify putative orthologs. If two protein sequences shared an amino acid identity ≥90% with query coverage ≥90%, they were considered to be orthologous.

Expression of R-M systems in *E. faecalis* heterologous hosts. Genes encoding the specificity and methylation subunits of Efa733I (EFSG_05028-EFSG_05027) were PCR-amplified in their entirety, including the upstream region to retain the native promoter, using primers 733_T1A_SM_F and 733_T1A_SM_R (see Table S1 for primer sequences). The PCR product was digested with *Not*I and ligated into *Not*I-digested pWH03 (16) using T4 DNA Ligase (NEB), generating pHA102. pWH03 is a pLT06 derivative for expression of genes from a previously validated neutral genomic insertion site (EF2238-EF2239) for expression (GISE) (16, 17). pHA102 constructs were then introduced into *E. coli* DH5α via heat shock for propagation and sequence confirmation. pHA102 was electroporated into *E. faecalis* OG1SSp using a previously described method (18). An *E. faecalis* OG1SSp derivative with a chromosomal integration of Efa733I, referred to as OG1SSp::*efa733I*, was generated by temperature shifts and *p*-chlorophenylalanine counterselection, as previously described (19).

Genes encoding the specificity and methylation subunits of Efa502I (EFQG_01131-EFQG_01132) were PCR-amplified using primers 502_T1A_SM_F and 502_T1A_SM_R. The PCR product was then TA-cloned into the pGEM-T Easy Vector (Promega) and introduced into

171 DH5α via heat shock to generate pGEM-SMA1. pGEM-SMA1 was then digested with *Not*I, and
172 the digestion reaction was used as insert for ligation into *Not*I-digested pWH03. The ligation
173 reaction was then introduced into DH5α, and colonies were screened for chloramphenicol
174 resistance and ampicillin susceptibility to ensure the pGEM backbone was not ligated into
175 pWH03. Once the construct, referred to as pHA103, was confirmed via Sanger sequencing, it
176 was introduced into electrocompetent *E. faecalis* OG1RF. An *E. faecalis* OG1RF derivative with
177 a chromosomal integration of Efa502I, referred to as OG1RF::*efa502I*, was generated by
178 temperature shifts and *p*-chlorophenylalanine counterselection. All plasmids and strains for
179 heterologous expression were validated by PCR and Sanger sequencing.
180
181 **Generation of *E. faecium* R-M deletion mutants.** Regions up- and downstream of Efa502I
182 and Efa733I were PCR-amplified using primers listed in Table S1, ligated into pLT06, and
183 transformed into *E. coli* EC1000 (20), generating pWH16 and pWH17 (Table 1). Insert
184 sequences were confirmed using Sanger sequencing. *E. faecium* strains were made
185 electrocompetent using previously a published protocol (21). 2 µg of sequence-confirmed
186 plasmids were electroporated into electrocompetent Efm733 and Efm502. The generation of
187 deletion mutants was accomplished using temperature shifts and *p*-chlorophenylalanine
188 counterselection, as previously described (19). The successful deletion mutants were
189 sequence-confirmed by PCR and Sanger sequencing.
190
191 **Transformation efficiency test.** Efm733, Efm502, and their respective R-M deletion mutants
192 were made electrocompetent using a modified version of the previously published protocol (21).
193 Briefly, overnight cultures were diluted 10-fold in BHI and cultured to OD_{600nm} ~ 0.6. The bacteria
194 were then pelleted and treated with filter-sterilized lysozyme buffer (10 mM Tris-HCl pH 8.0, 10
195 mM EDTA pH 8.0, 50 mM NaCl) supplemented with 83 µL of 2.5 KU/mL mutanolysin stock for
196 30 min at 37°C. The cells were then pelleted and washed three times with ice-cold filter-

197 sterilized electroporation buffer (0.5 M sucrose and 10% glycerol). Finally, the cells were
198 pelleted and resuspended in electroporation buffer and aliquoted for storage at -80°C and future
199 use. 1 µg pAT28 (22) was electroporated into the electrocompetent *E. faecium* cells. The counts
200 of total viable cells and spectinomycin-resistant cells were determined by serial dilution and
201 plating. The transformation efficiency was expressed as percent of transformed (spectinomycin-
202 resistant) cells per total viable cells. Three independent experiments were performed and the
203 statistical significance was assessed using the unpaired one-tailed Student's t-test.
204
205 **Distribution analysis of putative R-M systems and orphan MTases.** The amino acid
206 sequences for select R-M system and orphan MTase candidates were queried against a
207 collection of 73 *E. faecium* isolates previously analyzed by Lebreton *et al* (8) using BLASTP.
208 Any proteins which shared >90% query coverage and amino acid identity were considered
209 orthologs. The Fisher's exact test was used to determine if an orphan MTase or R-M system
210 was significantly over- or under-represented in a particular clade.
211
212 **REase protection assays.** To identify m5C methylation, gDNA was treated with the
213 methylation-sensitive REases McrBC, FspEI, and MspJI (NEB). 500 ng gDNA was incubated
214 with each REase at 37°C for 3 h (McrBC) or 6 h (FspEI and MspJI) followed by analysis by
215 electrophoresis on a 1% agarose gel with ethidium bromide.
216
217 **Bisulfite sequencing.** Whole-genome bisulfite sequencing libraries were constructed using the
218 Illumina TruSeq LT PCR FREE kit and the Qiagen EpiTect Bisulfite kit. Native DNA was isolated
219 as described above. Whole-genome-amplified (WGA) control DNA was generated by
220 amplification of native gDNA using the Qiagen REPLI-g® kit, per the manufacturer's
221 instructions. For bisulfite sequencing, briefly, 2 µg each of native and WGA control DNA were
222 fragmented using NEB fragmentase. DNA fragments ranging from 200 bp to 700 bp were gel

extracted and end-repaired. After A-tailing of DNA fragments, Illumina TruSeq adapters were ligated. Then, the bisulfite conversion was performed using the Qiagen EpiTect Bisulfite kit, per the manufacturer's instruction. An 8-cycle PCR enrichment with Illumina primer mix was performed, followed by size selection and gel purification. The libraries were sequenced using Illumina MiSeq with 2x75 bp paired-end chemistry.

Whole genome bisulfite sequencing analysis. The sequencing reads were analyzed using Bismark (23) with additional quality control and filtering as described previously (16). Briefly, the Illumina reads were mapped to the *in silico* bisulfite-converted references (23). Then, we quantified the conversion rate of each mapped read by calculating the percentage of converted C (which will result in T) to the total number of C in the reference within the mapped region. The mapped reads with ≤80% conversion rate were filtered out from analysis (16). Next, the coverage depth and methylation ratio were calculated for each C site. The methylation ratio was calculated by dividing the total number of C by the coverage depth at each C site. A fully methylated C, thus protected from bisulfite conversion, will have a methylation ratio near 1. An unmethylated C will have a methylation ratio near 0. To identify consensus methylation motifs, C sites with ≥0.35 methylation ratio and ≥10 coverage depth, along with the sequences of 5 bp upstream and 5 bp downstream, were extracted. The extracted sequences were subjected for MEME motif search (24).

Confirmation of m5C MTase activity. Primers EFSG_00659_F and EFSG_00659_R (Table S1) were used to amplify the entire Efm733 EFSG_00659 coding region and its upstream predicted promoter. The PCR product was then cloned into the pGEM-T Easy Vector (Promega) per the manufacturer's instructions and transformed into *E. coli* STBL4 (Fisher) to generate pRB01. REase digestion assays with methylation-sensitive enzymes were performed on purified *E. coli* and *E. faecium* gDNA as described above.

Accession numbers. DNA sequence data generated in this study have been deposited in the Sequence Read Archive under accession numbers PRJNA397049 (for SMRT sequencing data) and PRJNA488088 (for Illumina bisulfite sequencing data).

RESULTS

Identification of Clade A1-specific putative Type I R-M system in *E. faecium*. We previously reported that a Type II R-M system significantly reduces HGT via conjugation (18) and transformation (16) in *E. faecalis*. Here, we hypothesize that the *E. faecium* clades encode distinct R-M systems that reduce the exchange of genetic information between them. We utilized an approach we previously developed for *E. faecalis* R-M analysis (18) to predict potential R-M systems in eight previously sequenced *E. faecium* genomes. The 8 genomes included 3 genomes from Clade A1, 3 genomes from Clade B, one genome from Clade A2, and one recombinant Clade A1/B hybrid (5, 8). Because REases are difficult to identify with bioinformatics, and MTase prediction is comparatively straightforward, as has been previously reported by NEB (15), we first identified predicted DNA MTases in *E. faecium* genomes, and then analyzed surrounding genes for predicted R-M-related activities. The complete list of candidates for the eight strains is shown in Table 2.

Interestingly, we predicted at least one putative Type I R-M system for seven of the eight *E. faecium* strains (Table 2). Type I R-M systems are multisubunit complexes comprised of a specificity subunit (S), a methylation subunit (M), and a restriction subunit (R) (11, 25-27). The S subunit is responsible for the specific DNA recognition motif and associates with the DNA to bring the M and R subunits into contact. The system has two conformations: M_2S_1, which is capable of methylating DNA based on the recognition sequence, and $R_2M_2S_1$, which is capable of restricting DNA (27, 28). One predicted *E. faecium* Type I R-M system is comprised of highly

conserved (>90% amino acid sequence identity) M and R subunits in six of eight genomes across both Clade A1 and Clade B (Table 2 and Dataset S1). The specificity subunit from this system, however, is highly conserved in Clade A1 genomes but not in Clade B (Table 2 and Fig. 1a-b). S subunits possess two target recognition domains (TRDs) that determine the nucleotide sequence the subunit binds to (29, 30). The variation in amino acid sequence between the S subunits occurs within these TRDs (Fig 1a), suggesting that these S subunits recognize different DNA sequences. Notably, the S subunits from Clade A1 strains are identical to each other, indicating that they utilize the same recognition sequence.

To examine the distribution of this putative Clade A1-specific system in a larger collection of *E. faecium* strains, we analyzed 73 *E. faecium* genomes of mostly draft status that were reported previously (8). This list includes 15 clade B isolates, 21 clade A1 isolates, 35 clade A2 isolates, and 2 hybrid isolates (Table S2). We selected Efm502 (Clade A1) as our representative Clade A1 strain for this analysis and used Type I R-M sequences from this genome as references for analysis against the broader collection of *E. faecium* strains. The M and R subunits of the putative Clade A1-specific Type I system were detected in 51 and 52, respectively, of 73 *E. faecium* genomes, including both Clade A and Clade B strains (Fig S1a). However, the distribution of the S subunits varied (Fig S1a-b). The S subunit present in Efm502, EFQG_01131, was significantly enriched within Clade A1 isolates (14/21; p-value <0.0001 using Fisher exact test; Fig S1a) and absent from all other clades with the exception of strain EnGen002, which is classified as a Clade A1/B hybrid strain. Interestingly, the S subunits present in most other *E. faecium* strains are strain-specific by the strict thresholds applied here. Given that the Efm502 S subunit is enriched in Clade A1, we hypothesize that many Clade A1 strains exchange genetic information freely with each other while exchange with other *E. faecium* strains is restricted.

SMRT sequencing for *E. faecium* methylome analysis. We analyzed the Efm502 and Efm733 genomes by SMRT sequencing. SMRT sequencing measures the kinetics of DNA polymerase as it synthesizes DNA in order to identify bases that have been modified (31-33). It has been extensively utilized for bacterial methylome analysis (34-42). With SMRT sequencing, 6-methyladenine (m6A) and 4-methylcytosine (m4C) can be easily detected with modest sequence coverage (~25x per strand), while 5-methylcytosine (m5C) detections requires high coverage (~250x per strand) (41, 43). Using SMRT sequencing, we identified two unique m6A methylation motifs in Efm502 and Efm733. Efm502 possessed m6A methylation at the underlined position of the motif 5'-RAYCNNNNNNTTRG-3' and Efm733 possessed m6A methylation at the underlined position of the motif 5'-AGAWNNNNATTA-3' (Table 3). These sequences are asymmetric and bipartite, which is characteristic of Type I R-M methylation (12). Due to the coverage of our SMRT sequencing, m5C modification could not be accurately detected. The two unique m6A methylation patterns indicate that DNA from one strain would be recognized as foreign should it cross the strain barrier.

Expression in heterologous hosts links methylation activity to genes in Efm502 and Efm733. According to our predictions (Table 2), there is only one complete Type I R-M system encoded by each of Efm502 and Efm733. To determine if these systems are responsible for the methylation patterns identified by SMRT sequencing, we expressed the respective S and M subunits (EFQG_01131-01132 for Efm502 and EFSG_05028-05027 for Efm733) in the heterologous host *E. faecalis* OG1RF or its spectinomycin/streptomycin-resistant relative OG1SSp. Previous work in our lab had characterized the methylome of OG1RF using SMRT and bisulfite sequencing (16). This allowed us to attribute any new methylation patterns observed during SMRT sequencing to the *E. faecium* genes that were expressed in the OG1RF background. SMRT sequencing of these strains detected the same methylation patterns originally identified in Efm502 and Efm733 (Table 3). These data demonstrate that

EFQG_01131-01132 is responsible for the 5'-RAYCNNNNNNTTRG-3' methylation in Efm502 and that EFSG_05028-05027 is responsible for the 5'-AGAWNNNNATTA-3' methylation in Efm733. Because we have confirmed the function of these genes, we have named them Efa502I and Efa733I, which is consistent with the R-M system nomenclature convention established by New England Biolabs (12).

Efa502I and Efa733I reduce transformation efficiency in *E. faecium*. To determine whether the Type I R-M systems in Efm733 and Efm502 actively defend against exogenous DNA, we constructed null strains (Efm733ΔRM and Efm502ΔRM; Table 1) and evaluated their transformation efficiencies relative to their wild-type parent strains. Here, we utilized the broad host range plasmid pAT28 (Table 1) (22). pAT28 sequence has motifs recognized by the Type I R-M systems in both wild-type Efm733 (1 occurrence) and Efm502 (1 occurrence). The transformation of pAT28 into Efm733 and Efm502 served as a baseline for the experiment. If Efa733I and Efa502I are active, we expect to see higher pAT28 transformation efficiencies into Efm733ΔRM and Efm502ΔRM, respectively. Indeed, we observed significantly higher transformation efficiencies into Type I R-M system null strains (Fig 2; p-value<0.05 using one-tailed Student's t-test). These data demonstrate that the Type I R-M systems in Efm733 and Efm502 actively function as mechanisms of genome defense.

m5C methylation occurs in Efm733. As described previously, our SMRT sequencing had insufficient coverage depth for m5C methylome characterization. Hence, we used REase protection assays with commercially available methylation-sensitive REases to query the presence of m5C methylation in our eight *E. faecium* strains. Table 4 summarizes the recognition sequences and modifications of the enzymes used in this study. Only Efm733 showed evidence of cytosine modification, as it was digested by MspJI (Table 4; Fig S2).

353 To determine the exact cytosine methylation motif present in Efm733, gDNA was subjected to
354 whole-genome bisulfite sequencing. Whole genome amplified (WGA) DNA was used as
355 negative control since WGA removes all modifications. During bisulfite treatment, cytosine
356 bases are converted to thymine unless they are protected by either m4C or m5C methylation.
357 Additionally, our lab has previously published a method of distinguishing between m4C and
358 m5C methylation using thymine conversion ratios of sequencing reads after bisulfite treatment
359 (44). m5C methylation is sufficient to protect the cytosine residue completely from bisulfite
360 conversion, so that most sequencing reads at that position contain the original cytosine base.
361 However, m4C methylation provides only partial protection from bisulfite conversion, so a
362 thymine conversion rate of 0.5 at a particular position within the sequencing reads suggests the
363 presence of m4C methylation. Bisulfite conversion and subsequent sequencing revealed that
364 Efm733 possesses m5C modification at the motif 5'-R^{m}CCGGY-3' (Table 5, Fig 3, and Fig S3;
365 the methylation occurs at the underlined position), which overlaps the MspJI recognition site (5'-
366 CNNR-3') and hence supports the evidence of methylation obtained from the MspJI digestion
367 assays. Based on the cytosine conversion ratio of close to 1.0, m5C modification is supported,
368 which is consistent with why it was not detected by our SMRT sequencing.
369
370 **EFSG_00659 is responsible for m5C methylation in Efm733.** Based on the bioinformatics
371 analyses, we hypothesized that EFSG_00659 was responsible for the m5C methylation found in
372 Efm733 (Table 2). EFSG_00659 possessed no homologs in the other seven strains analyzed,
373 making it a good candidate for the unique methylation found in Efm733. We queried the
374 EFSG_00659 protein sequence against the REBASE gold standard list and identified that it has
375 high sequence similarity to M.AvaIX, M.VchO395I and M.VchAI (e-value ≤ 3e^{-125}; recognition
376 sites are 5'-RCCGGY-3'). Interestingly, BLASTP identified no significant hits when
377 EFSG_00659 was queried against the larger collection of 73 *E. faecium* genomes, indicating its
378 unique presence in Efm733.

In order to link EFSG_00659 with the m5C methylation identified during bisulfite sequencing, we expressed it in the heterologous host *E. coli* STBL4 and performed an REase protection assay. The REase AgeI recognizes the motif 5'-ACCGGT-3', and its enzymatic activity is blocked if m5C methylation is present at the underlined position. This motif overlaps the m5C methylation motif in Efm733 identified by bisulfite sequencing. If the motif is methylated, DNA will be protected against digestion. We cloned EFSG_00659 into the vector pGEM-T and transformed it into *E. coli* STBL4, generating strain *E. coli* STBL4(pRB01). Genomic DNA from Efm733, STBL4(pGEM-T), and STBL4(pRB01) was treated with AgeI per the manufacturer's instructions. EcoRI was used as a positive control for digestion. Figure 4 shows representative results of the digestions on a 1% agarose gel. As expected, Efm733 was digested by EcoRI and protected against digestion from AgeI. STBL4(pGEM-T) was digested by both EcoRI and AgeI, indicating that the original host and empty vector pGEM-T did not possess the appropriate m5C methylation. STBL4(pRB01) was protected against digestion by AgeI, demonstrating that EFSG_00659 is responsible for the 5'-R^{m}CCGGY-3' methylation found in Efm733.

DISCUSSION

In this study, we used a combination of genomic and genetic approaches to identify a functional Type I R-M system that is enriched in Clade A1 *E. faecium* and that significantly alters transformability of a model Clade A1 strain. We propose that this R-M system impacts HGT rates among *E. faecium* mixed-clade communities, thereby helping to maintain the observed phylogenetic structure of *E. faecium* and facilitating HGT specifically among Clade A1 strains. Mixed communities of *E. faecium* clades are expected to occur in environments where healthy and ill human hosts, human and animal hosts, and/or the feces of any of these hosts co-mingle (i.e. in sewage). In future studies, we plan to assess the impact of R-M on conjugative plasmid

404 transfer, which is a major mode of HGT in enterococci and was not assessed in our current
405 study.
406
407 An interesting observation from our study is the sequence diversity of Type I S subunits
408 encoded within *E. faecium* Type R-M systems having nearly identical R and M subunits (Fig
409 S1a-b). After further investigation into those alignments, we found that those S subunits sharing
410 50-70% overall amino acid sequence identities possess sequence diversity within one TRD
411 domain, where the other TRD domain and the central conserved domain are conserved. This
412 suggests that these systems share partial recognition sequences. Previous research has
413 reported that the diversification of Type I R-M recognition sequences is driven by TRD
414 exchanges, permutation of the dimerization domain, and circular permutation of TRDs (45). Our
415 observation suggests that TRD recombination and reorganization events occur for *E. faecium*
416 Type I R-M systems outside Clade A1. Future studies will use genomics to further explore the
417 relationship between S subunit sequence diversity and its impact on *E. faecium* methylomes
418 and inter-strain and inter-clade HGT.

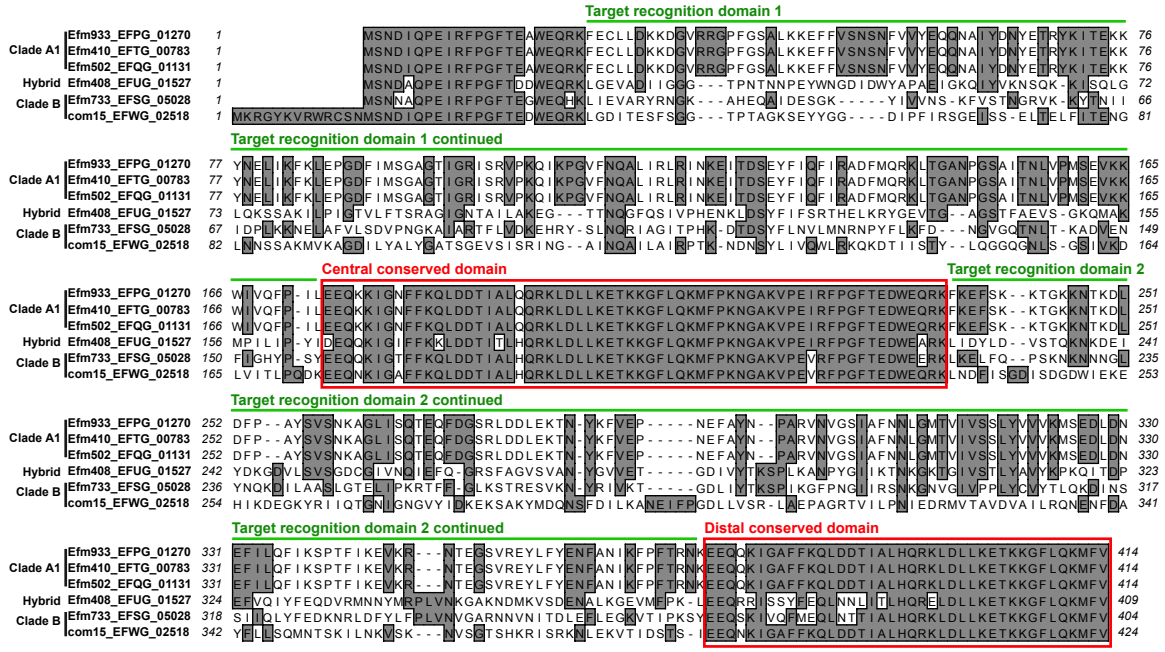
568 [1]Recognition sequences and methylation patterns were retrieved from NEB.

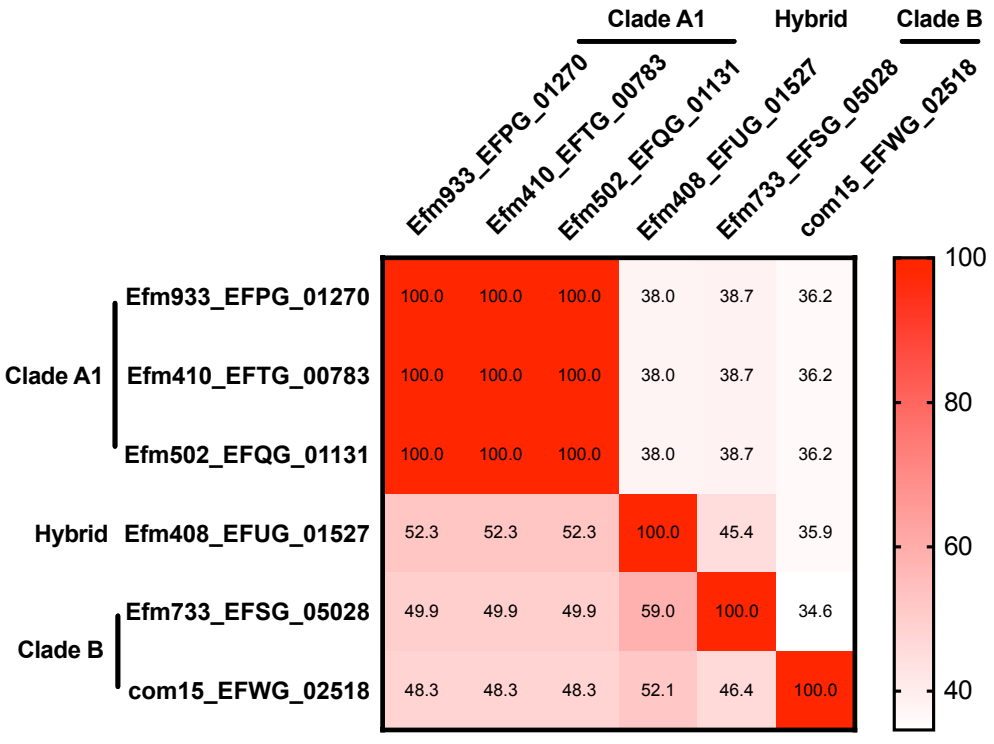
Table 5. Bisulfite sequencing results.

	methylation motif	methylation position	methylation type	# motifs detected[a]	# motifs in genome	# motif pass cvg filter	average methylation ratio[b]	mean motif coverage[c]
733	5'-RCCGGY-3'	2	m5C	748	780	750	96.5% (6.2%)	61.5X

[a]# motifs detected is defined as motifs with coverage depth more than 10X and methylation ratio >=0.35.
[b]Average methylation ratio is defined as the mean of the methylation ratio from all motifs in the genome.

a).





b).

Figure 1. Conservation and variability of S subunits. The protein sequences of predicted S subunits from 6 (out of 8) representative *E. faecium* genomes were pairwise

aligned using MacVector. The alignment is shown in (a). Central and distal conserved domain was identified based on sequence homology and labeled in red (30). The target recognition domains were interpreted based on conserved domains as labeled in green. The percent identity of each pair is shown in (b). White to red: low to high percent identities. Each number represents percent identity of one protein sequence (row name) to another (column name).

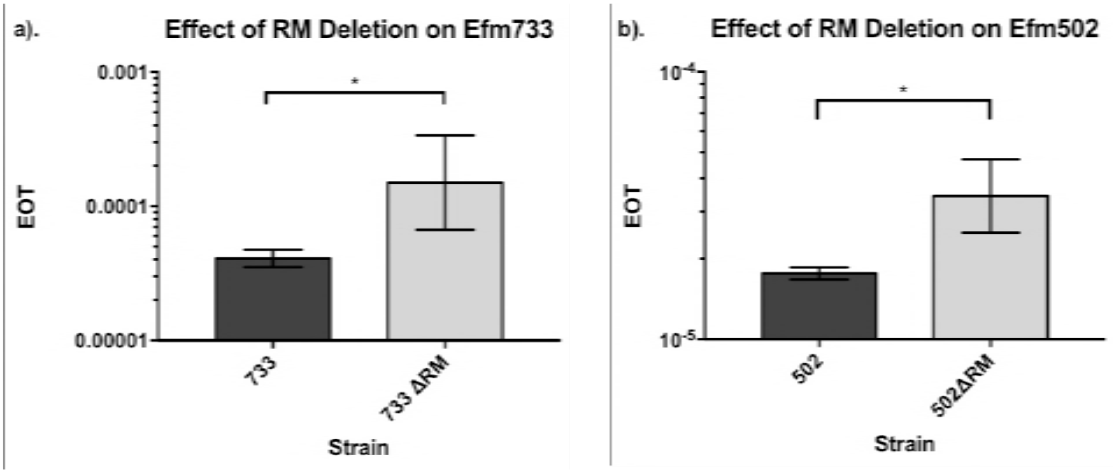


Figure 2. Type I R-M systems reduce transformability of Efm733 and Efm502. Three independent transformation experiments were performed. There is a statistical difference between the transformation efficiency of pAT28 into wild type and R-M null strains of Efm733 and Efm502. EOT: Efficiency of transfer. *: $p < 0.05$.

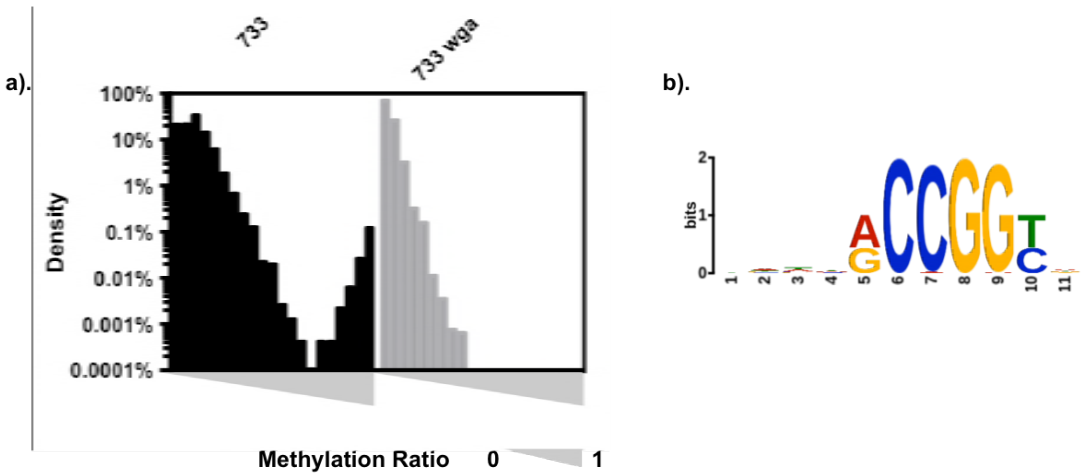

Figure 3. Bisulfite sequencing results for Efm733. a) Efm733 gDNA and its whole genome amplified (WGA) control were bisulfite-converted, and the methylation ratio for each cytosine site was calculated. Efm733 gDNA has cytosines with methylation ratios near 100%, indicating the presence of m5C methylation. b) All sites with ≥0.35 methylation ratio from native gDNA samples were extracted, together with 5 bp upstream and 5 bp downstream. The sequences are subjected for consensus motif analysis using MEME. The consensus motif identified by this analysis is shown.

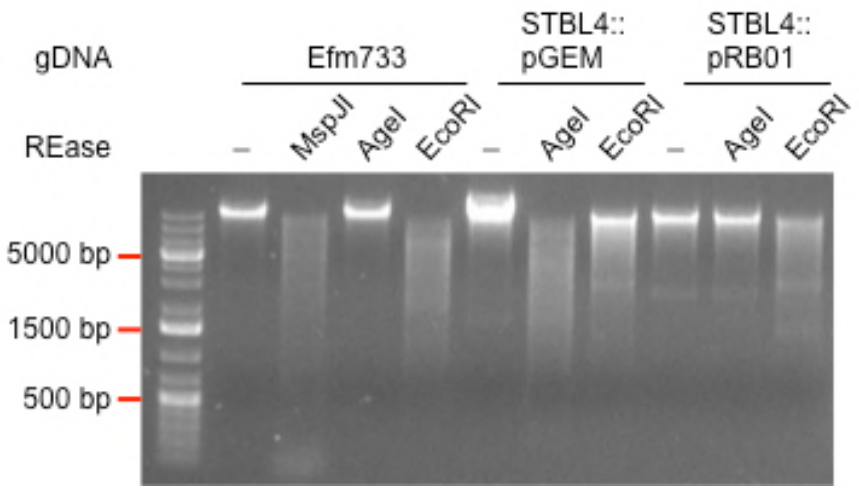

Figure 4. EFSG_00659 confers protection against AgeI digestion. AgeI digestion reactions were analyzed by agarose gel electrophoresis with ethidium bromide staining. Bacterial gDNA was used as substrate for REase reactions. Expression of the Efm733 gene EFSG_00659 in *E. coli* STBL4 protects *E. coli* gDNA from AgeI digestion. EcoRI is a positive control for digestion. -, no enzyme added.
