18

19 **Abstract**

20 The Snail superfamily of transcription factors have a modular organization and their
21 similarities and divergences are the basis for subdividing the superfamily into the Snail1/2 and
22 Scratch families. As it is generally accepted that the Snail and Scratch families originated through
23 gene duplication, understanding the functional contribution of each module could provide us with
24 further insight about the molecular and functional evolution of the Snail superfamily. Thus, in this
25 work, we investigated the function of the SNAG and SCRATCH domains in chicken Scratch2.
26 Through evolutionary comparison analysis we identified a novel HINGE domain that lies between
27 the SNAG and SCRATCH domain. Similar to members of the Snail1/2 families, Scratch2-
28 mediated transcriptional repression requires SNAG and nuclear localization requires the zinc-
29 finger domain. We also identified a novel HINGE domain that lies between the SNAG and
30 SCRATCH domain. HINGE is highly conserved in amniotes. Single mutations of the conserved
31 Tyrosine and Serine residues of HINGE downregulated Scratch2-mediated transcriptional
32 repression. This effect depended on the presence of the SCRATCH domain.

33 **Introduction**

34 The members of the Snail superfamily of transcription factors are key players in multiple
35 embryological and pathological events (reviewed in [1] acting mainly as transcriptional repressors
36 [2–4]. Similarities and divergences in their sequences subdivides the superfamily into the Snail1/2
37 and Scratch families. This subdivision was originally based on sequence homology comparison,
38 but it clearly correlates with functional differences as well. Both Snail and Scratch families
39 modulate cell adhesion and migration. Whilst the effect of Snail is broader [5–7], Scratch is limited

40 to neural development, regulating neuronal migration during cortical formation, promoting neural
41 fate and repressing neural precursor cell death [8–10].

42 All Snail superfamily members have a modular organization, including a conserved carboxy-
43 terminal region containing zinc-fingers and a SNAG (Snaill/Gfi-1) domain in the amino-terminus.
44 Scratch and Snail2 proteins present distinct conserved domains between the SNAG and zinc-
45 fingers domains, called SCRATCH and SLUG domains, respectively. The correlation between
46 domains and function has been much better characterized in the Snail than in the Scratch family.
47 The zinc-finger region of Snail proteins recognizes a consensus DNA motif containing a core of
48 six nucleotides known as E-boxes [11], and the SNAG domain of Snail1 interacts with a histone
49 lysine-specific demethylase, repressing target genes [12]. The SLUG domain has also been
50 reported to contribute to repression [13] and members of the Snail family that lack a SNAG domain
51 repress through an alternative domain known as the CtBP domain [14].

52 In Scratch1, the repressor domain has also been attributed to the amino-terminus of the
53 protein, but deletion of the SNAG domain in human Scratch1 does not reduce its ability to repress
54 E-box-driven transcription [4]. Further, the Scratch family lacks an obvious alternative module
55 such as the CtBP domain. Thus, the repressor domain in the Scratch family remains undefined. As
56 it is generally accepted that the Snail and Scratch families originated through gene duplication,
57 with the signature domains of each family arising through divergence of an ancestral gene [15],
58 understanding the functional contribution of each module could provide us with further insight
59 about the molecular and functional evolution of this superfamily.

60 In this work, we have investigated the biological role of different domains in Scratch2 (Sct2)
61 through deletion and point mutations in the chicken orthologue. Our data suggest that Sct2
62 requires SNAG for its repression activity. Also, we identified another conserved motif- HINGE-

63 that co-evolved with the SCRATCH domain. Scrt2-mediated transcriptional repression can be
64 modulated by the SCRATCH domain through modifications in the HINGE -a novel region
65 conserved in the Scrt2 subfamily.

66 **Material and methods**

67 *Generation of mutated and truncated proteins*

68 The pCIG-MYC-*cScrt2* containing chicken Scrt2 cDNA (JN982016.1) was previously
69 cloned in our laboratory [16] and has been used as a template for the generation of wild-type
70 truncated constructs. Full-length N-terminal FLAG-tagged single mutation constructs harboring
71 substitutions tyrosine 77 to phenylalanine (*cScrt2*-Y77F) or glutamate (*cScrt2*-Y77E), or serine 78
72 to alanine (*cScrt2*-S78A) or aspartate (*cScrt2*-S78D) were synthesized by GenScript USA Inc.
73 (Piscataway, NJ). N-terminal FLAG-tagged *cScrt2*ΔSCRATCH (aa 97-116 deletion), the full-
74 length double mutation constructs containing both Y77F and S78A (*cScrt2*-YS/FA) or Y77E and
75 S78D (*cScrt2*-YS/ED), and Y77 or S78 substitutions in the absence of the SCRATCH domain
76 (YFΔSCRATCH or SAΔSCRATCH) were synthesized by Integrated DNA technologies (IDT).
77 All commercially purchased constructs were subcloned into pCIG, where expression of a
78 bicistronic RNA with nuclear GFP reporter is driven by chicken beta-actin promoter [17]. The
79 sequences for *cScrt2*ΔZnF (aa 1-127), *cScrt2*ΔN (aa 124-276), *cScrt2*ΔSNAG (aa 10-276),
80 *cScrt2*S78AΔSNAG (aa 10-276, S78A) and *cScrt2*YS/FAΔSNAG (aa 10-276, Y77F and S78A)
81 were PCR amplified flanked by EcoRI and SmaI sites and subcloned into pCIG or pMES. The
82 latter differs from pCIG in that it the GFP lacks a nuclear localization signal and remains in the
83 cytoplasm [18].

84

85 *In ovo electroporation*

86 Chicken embryos at stage HH10-HH12 [19] were electroporated with *cScrt2*WT, *cScrt2*-
87 Y77F and *cScrt2*-S78A. Electroporated cells were identified by the presence of GFP. Briefly, a
88 small window was made at the top of the egg shell to reach the embryo. The embryos were
89 visualized with sterile Indian ink 10% (diluted in Howard Ringer's saline solution) injected under
90 the blastoderm. The plasmid solution (concentration of 3 µg/ml) containing the inert tracer
91 FastGreen 0.2% was injected into the truncal neural tube lumen. Then, the platinum electrodes
92 were placed at a distance of 4 mm flanking the neural tube and 5 pulses of 20 V with 30 ms of
93 length and 100 ms of interval were administered [17,20]. Embryos were re-incubated and collected
94 24 hours later.

95

96 *HEK293T culture and transfection*

97 Established HEK293T cells were cultured in DMEM supplemented with 10% FBS and 1%
98 antibiotics (streptomycin 5 µg/ml and penicillin 5 U/ml). Transfection was performed with 2 µg
99 Lipofectamine 2000 (Invitrogen) and 0.8 µg of the DNA construct per well in 24-well plates for 4
100 hours in Opti-MEM medium without antibiotics. After 4 hours of transfection, the cells were
101 washed with serum-free medium and fed with complete DMEM medium. The cells recovered for
102 16–18 hours before fixation.

103

104 *Immunofluorescence*

105 Embryos were fixed in PBS/paraformaldehyde 4% for 30 minutes and cryoprotected with
106 20% sucrose overnight at 4°C and embedded in an OCT-20% sucrose mixture (1:1) prior to
107 sectioning in cryostat at 10 µm. We sectioned the trunk region of the embryo between the limb
108 buds. The slides were dried for 30 minutes at 37°C, fixed in PBS/paraformaldehyde 4% for 20

109 minutes, washed three times of 10 minutes with PBS and blocked for 1 hour with 3% NGS and
110 1% BSA diluted in PBST (PBS containing 0,1% Triton X-100), followed by incubation with
111 antibodies. Coverslips containing transfected HEK293T cells were washed once with PBS for 10
112 minutes and then fixed in PBS/paraformaldehyde 4% for 20 minutes. Next, the coverslips were
113 washed with PBS and incubated with blocking solution (PBS containing 0,1% Triton X-100 and
114 3% NGS), followed by incubation with antibodies. Primary antibodies were diluted in the block
115 solution and applied on sections or cells overnight at room temperature in a humidified chamber.
116 In the next day, the slides or coverslips were washed with PBS and then incubated with the
117 secondary antibody for 2 hours at room temperature. DAPI was added to the secondary antibody
118 solution for nuclear staining. Primary antibodies used were: anti-MYC (0,004 mg/ml – 9E10, Life
119 Technologies), anti-GFP (0.002 mg/ml - A-11122, Life Technologies), anti-FLAG (1:250 - F3165,
120 Sigma). Secondary antibodies used were goat anti-rabbit IgG Alexa Fluor 488 (1:500, Molecular
121 Probes) and anti-mouse IgG Alexa Fluor 568 (1:500, Molecular Probes) or 647 (1:500, Molecular
122 Probes).

123 *Luciferase assay*

124 For these experiments, we inserted four E-Box sequences (CAACAGGTG) in *tandem* into
125 pGL3Luc vector (Promega), generating the plasmid-test pGL3-4xE-box. This plasmid is used to
126 indirectly measure the transcriptional activity of Scrt2 through the activity of luciferase. To
127 perform the assay, HEK293T cells were dissociated and plated in 24-well plates at the
128 concentration of 1.25×10^5 cells/well. The cells were transiently co-transfected with each plasmid
129 containing the tested constructs together with pGL3-4xE-box and pRL encoding the renilla
130 luciferase. Renilla luciferase is transcribed independently of Scrt2 and served as a normalization

131 factor for the assay. Control conditions were the same, except that the tested construct (pMES or
132 pCIG) did not contain cScrt2 or its variants.

133 The co-transfection was performed with Lipofectamine 2000 (Invitrogen) at a final
134 concentration of 2 µg, 0.4 µg of tested plasmids, 0.01 µg of pRL and 0,4 µg pGL3-4xE-box for 4
135 hours in Opti-MEM medium. After 4 hours, the medium containing the transfection solution was
136 removed, the cells were washed with serum-free medium and cultured with complete medium. The
137 cells were re-incubated for 16-18 hours before collection and luciferase signal was measured
138 following the kit manufacturer's instructions (Dual luciferase assay reporter system, Promega).
139 Statistical analysis was performed using one-way ANOVA. The level of significance adopted was
140 $p < 0.05$.

141

142 Results

143 *The zinc-finger domain of Scrt2 determines subcellular localization*

144 The main activity reported for members of the Snail superfamily is transcriptional
145 repression. This is due to the joint effect of the zinc-finger domain, mediating nuclear translocation
146 and DNA-binding activity, and the SNAG domain, mediating the repressor activity [12]. To
147 investigate the role of the zinc-finger domain in Scrt2 nuclear localization, we expressed a series
148 of truncated chicken Scrt2 proteins that included or excluded the zinc-fingers, as well as the
149 conserved domains SNAG and SCRATCH, in different combinations (Fig. 1A).

150 **Figure 1 - Nuclear localization of chicken Scrt2 depends on the zinc-finger domain while the**
151 **transcriptional repression activity is regulated by SNAG domain.** (A) Diagram on the left represents
152 chicken Scrt2 full length protein (amino acids 1-276). The different domains are represented with a color
153 code: the SNAG domain (1 to 9 aminoacids) in red, the SCRATCH domain (97 to 116 aminoacids) in

154 green, and the five zinc fingers, comprising the DNA binding domain, in yellow. MYC-tag and FLAG-tag
155 are represented in magenta and blue, respectively. *cScrt2*WT corresponds to the full sequence, with a MYC-
156 tag at the N-terminal region. Below *cScrt2*WT are represented, in order, the diagrams for *cScrt2*ΔZnF
157 (amino acids 1 to 127), *cScrt2*ΔN (amino acids 124 to 276), *cScrt2*ΔSCRATCH (deletion of amino acids
158 97-116) and *cScrt2*ΔSNAG (amino acids 10 to 276). Co-localization with nuclear GFP and DAPI indicates
159 that expression of *cScrt2*WT (B-D), *cScrt2*ΔN (H-J), *cScrt2*ΔSCRATCH (K-M), and *cScrt2*ΔSNAG (N-P)
160 localize to the nucleus in HEK293T. In contrast, *cScrt2*ΔZnF expression is restricted to the cytoplasm (E-
161 G, arrows). (B) Whereas *cScrt2*WT reduced transcription factor-activated luciferase activity relative to
162 control conditions, removal of SNAG (*cScrt2*ΔSNAG) induced luciferase activity to levels similar to
163 control, suggesting that the absence of SNAG decreases chicken Scrt2-mediated transcriptional repression.
164 In contrast, chicken Scrt2 lacking the SCRATCH domain (*cScrt2*ΔSCRATCH) repressed transcription with
165 the same efficiency as *cScrt2*WT. In control conditions, HEK293T cells were transfected with pGL3-4xRE-
166 box and empty pCIG vector. *cScrt2*WT, *cScrt2*ΔZnF, *cScrt2*ΔSCRATCH and *cScrt2*ΔSNAG are inserted
167 into pCIG vector while *cScrt2*ΔN is inserted into pMES vector. Results show the scatter plot distribution
168 of at least triplicate samples from three different experiments, +/- standard deviation. The data was analyzed
169 by one-way ANOVA. *p<0.0001 **p=0.0007 ***p=0.02. Scale bar: 20μm

170 *cScrt2*ΔZnF, lacking the zinc-finger but including the SNAG and SCRATCH domains, was
171 found only in the cytoplasm (Fig. 1E-G, arrows) of transfected HEK293T. In contrast, all the
172 truncations that included the zinc-finger domain, that is, Scrt2 lacking either the SNAG
173 (*cScrt2*ΔSNAG) or SCRATCH (*cScrt2*ΔSCRATCH) domains or containing only the zinc-finger
174 motif (*cScrt2*ΔN), segregated to the nuclei of HEK293T cells (Fig. 1H-P).

175 As reliable Scrt2-reactive antibodies are lacking, we used epitope-tagged Scrt2 for these
176 experiments, first assessing if the presence of the epitope tag affected Scrt2 subcellular
177 localization. Consistent with its reported role as a DNA-binding transcription factor, MYC-tagged

178 Scrt2 co-localized with the nuclear DAPI stain in HEK293T cells and in embryonic neural cells
179 (Fig. 1B-D and Fig. S1).

180

181 ***Scrt2 repressor activity requires the conserved SNAG domain but not the SCRATCH domain***

182 In most members of the Snail superfamily, transcriptional repressor activity requires the
183 conserved amino-terminus SNAG domain (Fig. 2) [13]. Accordingly, removing the SNAG domain
184 (*cScrt2* Δ SNAG) decreased Scrt2-mediated transcriptional repression significantly (Fig. 1Q),
185 without affecting its nuclear localization (Fig. 1O).

186 **Figure 2 - Chicken Scrt2 has conserved amino acid domains.** Top diagram represents full length chicken
187 Scrt2 with its protein domains. Chicken Scrt2 sequence conservation was analyzed in a variety of
188 organisms with Ugene and ClustalW programs. Deeper hues reflect higher degree of conservation. SNAG
189 (red box), HINGE (black box) and SCRATCH (green box) domains display high degree of conservation.
190 The HINGE domain displays a strongly conserved sequence (EEYSDPESPQS, amino acids 75-85 – black
191 box) before the SCRATCH domain, suggesting that this region might be important for chicken Scrt2
192 function. Accession numbers for the sequences used are in Fig. S2B. Python and Baiji sequences are partial.

193 Besides the SNAG and zinc-finger domains, additional domains are conserved in different
194 branches of the Snail superfamily and are used for their phylogenetic classification. In particular,
195 the majority of the members of the ScratchB [21] branch of the Scratch family have the SCRATCH
196 domain. Here, we consider the SCRATCH domain as the full AVTDSYSMDAFFITDGRSRR
197 sequence (aminoacids 97-116 in chicken Scrt2, Fig. 2). This domain lies between the SNAG and
198 zinc-fingers domains, and its function remains unknown [21]. As SCRATCH was not required for
199 Scrt2 nuclear localization (Fig. 1), we next evaluated the effect of removal of SCRATCH domain
200 on transcriptional repressor activity. The truncated form *cScrt2* Δ SCRATCH displayed

201 transcriptional repression similar to the native form *cScrt2*WT, suggesting that SCRATCH is
202 required neither for nuclear localization nor for repressor activity (Fig. 1Q).

203 ***HINGE domain Ser and Tyr residues are required for Scrt2 repressor activity.***

204 To further investigate the role of the SCRATCH domain, we analyzed its evolution in the
205 context of Scrt2 proteins through sequence alignment (Fig. 2). We observed that the full
206 SCRATCH domain co-evolved in vertebrates together with another conserved domain that we
207 named HINGE (amino acids 75-85 in chicken Scrt2; Fig. S2A). HINGE is extremely well
208 conserved in amniotes and contains an initial acidic-rich motif EEYSD. The acidic residues of the
209 motif can vary between glutamate and aspartate, but the core residues Tyrosine₇₇ (Y77) and
210 Serine₇₈ (S78) are maintained in most vertebrates – except fish. Furthermore, these two residues
211 are potentially recognized by a variety of kinases (Fig. S3). As changes in phosphorylation levels
212 modulate protein stability and repressor activity of Snail1/2 [22], we hypothesized that these
213 residues are evolutionarily conserved due to their ability to modulate Scrt2 function through
214 phosphorylation.

215 To test this hypothesis, we generated a series of single mutants at residues 77 and 78 to
216 simulate the changes in residue charges prior and after phosphorylation. We replaced the original
217 amino acids either with the neutral residues closest in structure to tyrosine or serine, or with acidic
218 residues. Thus, Y77 was replaced with phenylalanine (*cScrt2*-Y77F) or glutamate (*cScrt*-Y77E)
219 and S78 with alanine (*cScrt*-S78A) or aspartate (*cScrt2*-S78D). All four single mutations impaired
220 Scrt2-mediated transcriptional repression (Fig. 3M).

221 **Figure 3 - Mutations in residues Y77 or S78 do not alter the subcellular localization of Scrt2 but**
222 **reduce the transcriptional repression activity.** FLAG-tagged *cScrt2*-Y77F (A-C), *cScrt2*-Y77E (D-F),
223 *cScrt2*-S78A (G-I) and *cScrt2*-S78D (J-L) remain in the nucleus of HEK293T cells after transfection. FLAG
224 immunostaining co-localizes with nuclear GFP and DAPI. *cScrt2*-Y77F, *cScrt2*-Y77E, *cScrt2*-S78A were

225 inserted in a pCIG vector whereas *cScrt2*-S78D was inserted in a pMES vector. (M) The single mutant
226 forms *cScrt2*-Y77F, *cScrt2*-Y77E, *cScrt2*-S78A and *cScrt2*-S78D have reduced transcriptional repression
227 activity compared to *cScrt2*WT (**), although the remaining activity is sufficient to produce a significant
228 reduction in luciferase signal when compared to control (*). Results shown are the mean of 3 independent
229 experiments performed on triplicate samples. The data were analyzed with one-way ANOVA non-
230 parametric pairwise comparison and are represented as mean with standard deviation. * p<0.001; **
231 p=0.047; *** p=0.0164; @ p=0.04; # p= 0.006. Scale bar: 20µm

232 Reduction of transcriptional activity could not be attributed to changes in Scrt subcellular
233 localization, as all constructs were found in the nucleus (Fig. 3B, E, H and K). Moreover, these
234 mutations did not change protein expression levels (data not shown).

235 As our homology analysis suggested a co-evolution of the HINGE and SCRATCH domains,
236 we hypothesized that the two domains act together, which would mean that removing the
237 SCRATCH domain in the background of Y77 or S78 single mutants should further decrease Scrt-2
238 repressor activity. Contrary to our hypothesis, removal of the SCRATCH domain restored the
239 repressor activity of *cScrt2*-Y77F and *cScrt*-S78A (Fig. 4).

240 **Figure 4 - Mutation of Y77 or S78 does not reduce transcriptional repressor activity in the absence**
241 **of SCRATCH domain.** Mutation of the Y77 or of the S78 residues in the absence of the SCRATCH
242 domain (YFΔSCRATCH or SAΔSCRATCH) does not alter the chicken Scrt2 transcriptional repression
243 activity. Results shown are the mean of 5 independent experiments performed on triplicate samples.
244 Statistical significance was calculated using one-way ANOVA multiple comparisons. *p<0.0001;
245 **p=0.02; #p=0.0001; @p=0.0009.

246

247 ***Double mutants of the HINGE domain repress transcription***

248 Considering that single mutations of either Y77 or S78 decreased Scrt2 repressor activity
249 and that invertebrates lack the entire HINGE domain (Fig. 2), we next tested the effect of

250 simultaneously mutating both sites in Scrt2 (*cScrt2*-YS/FA and *cScrt2*-YS/ED). These double
251 mutants did not differ significantly from wild type Scrt2 in their ability to repress transcription
252 (Fig. 5A).

253 **Figure 5 - Simultaneous mutations in residues Y77 and S78 do not affect chicken Scrt2 activity.**

254 Transcriptional repression activity of the double mutant forms, *cScrt2*-YS/FA and *cScrt2*-YS/ED is similar
255 to *cScrt2*WT (A). Removal of the SNAG domain (YS/FA Δ SNAG) partially reduces the repressor activity
256 of the double mutant form *cScrt2*-YS/FA (B). Results shown are the mean of 3 independent experiments,
257 performed on triplicate samples. Statistical significance was calculated using 1-way ANOVA. * $p < 0.0001$;
258 ** $p = 0.02$

259 Considering the importance of the conserved SNAG domain in transcriptional repression,
260 we next asked if the double mutants also repressed transcription through this domain. Indeed, when
261 we compared the repressor activity of the double mutant (*cScrt2*-YS/FA) in the presence or
262 absence of the SNAG domain (Δ SNAG), the absence of SNAG partially decreased repressor
263 activity in the double mutant (Fig. 5B).

264

265 **Discussion**

266 We have dissected here the contributions of evolutionarily conserved domains in Scrt2
267 towards its transcriptional repression activity. In particular, we focused on the importance of the
268 SNAG and SCRATCH domain and identified a novel conserved region called HINGE. Removal
269 of SNAG and single-residue mutations in HINGE domain downregulated transcriptional
270 repression.

271 Extensive phylogenetic comparison of the SNAG domain in the Snail superfamily suggests
272 that it can be subdivided into two separate subdomains: SNAG-1 and SNAG-2. SNAG-1 is defined

273 as the small domain of highly conserved residues, also known as the minimal SNAG
274 (MPRSFLVKK), whereas SNAG-2 contains the subsequent 13-17 amino acids [21]. SNAG-1 and
275 SNAG-2 do not necessarily occur in the same protein; in other words, the two subdomains can
276 evolve independently, suggesting that they contribute to different functions. Scratch proteins -
277 including Sct2- all lack a recognizable SNAG-2 subdomain. However, Sct2 retains a SNAG-1
278 subdomain identical to that found in Snail1. Our data shows that removal of SNAG-1 decreased
279 Sct2 repressor activity but not protein stability. In light of this, a more complex picture of SNAG-1
280 and 2 function arises. The canonical model of SNAG-mediated repression in the Snail superfamily
281 relies on the functional analysis of Snail1, after simultaneously removing SNAG-1 and 2. In these
282 experiments, repressor activity was completely abolished, and protein stability reduced [12,13].
283 Repressor activity has been attributed to the interaction of individual residues in SNAG-1 to
284 repressor proteins and epigenetic modifiers. For example, Lysine-specific demethylase 1 (LSD1)
285 interacts with Pro₂ and Arg₃ of Snail's SNAG-1 domain [12,13]. Further, the Ajuba family of LIM
286 repressor proteins interacts with Phe₄ in SNAG-1 [23]. Together, these data suggest that the
287 SNAG-1 domain is the minimal domain required for transcriptional repression, whereas SNAG-2
288 might be more relevant for Snail1 protein stability.

289 We also identified and analyzed the role of another evolutionarily conserved domain
290 (HINGE), that lies between the SNAG and SCRATCH domains, containing potential
291 phosphorylatable sites. As phosphorylation of Snail1 and 2 modulate their stability and repressor
292 activity [22], we explored the importance of these residues for Sct2 function through point
293 mutations. Our mutations focused in changing the charge of the original residues, substituting them
294 by the neutral residues alanine and phenylalanine or by the negatively charged residues aspartate
295 and glutamate: substitution with alanine or phenylalanine generates a non-phosphorylatable form,

296 whereas substitution with aspartate or glutamate simulates the negative charge provided by
297 phosphorylation [22,24]. Thus, if phosphorylation at these residues modulated Sct2 activity,
298 negatively charged and neutral charge point mutations should yield opposite results. Instead, all
299 single point mutations decreased Sct2 transcriptional repressor activity irrespective of the residue
300 charge, suggesting that the replacement of these amino acids affects Sct2 activity through changes
301 in protein conformation. Without definitive crystallographic information, our interpretation of the
302 single and double mutant data is that this region acts as a hinge. Interestingly, double mutants
303 restored repressor activity, but in a SNAG-dependent manner: with SNAG deleted, double
304 mutations did not restore transcriptional repression. Thus, the double mutations might have
305 rearranged protein conformation so as to expose SNAG in a position that allows co-repressor
306 recruitment.

307 The mutations in the HINGE domain also revealed a putative modulatory role for the
308 SCRATCH domain on Sct2 function: in single mutations of either residue, 77 or 78 of HINGE,
309 concomitant removal of the SCRATCH domain restored transcriptional repressive activity.
310 However, removal of SCRATCH did not affect Sct2 activity in the background of an intact
311 HINGE domain containing Tyrosine77 and Serine78. Thus, the modulatory activity of SCRATCH
312 depends on the identity of the residue on position 77 or 78 at the HINGE domain, suggesting that
313 their function evolved in concert. Indeed, our phylogenetic analysis indicate that the HINGE
314 domain co-evolved with the SCRATCH domain. Conservation of the SCRATCH domain is higher
315 amongst species that contain both Tyrosine and a Serine in the HINGE domain (Fig. S2). If true,
316 the salmon and zebrafish Sct2 orthologues, which present the Tyrosine but not the Serine residue
317 in the HINGE domain (EEYCD), might present a conformation where SCRATCH is constitutively
318 modulating transcriptional repression, and thus would present a lower activity than their avian or

319 mammalian counterparts. In the case of these latter species, which have fully conserved HINGE
320 domains, post-translational modifications in HINGE could change its conformation so as to
321 activate the modulatory role of SCRATCH. In this scenario, addition of a single negative charge,
322 possibly through phosphorylation at position 77 or 78, would be sufficient to activate SCRATCH-
323 domain-mediated reduction of Sct2 transcriptional repression. Although our data shows that
324 changing residue 77 or 78 to a neutral aminoacid has the same effect as a substitution for a
325 negatively-charged one, we cannot rule out the possibility that experimental substitutions of
326 aminoacid residues fail to completely reproduce the changes triggered by phosphorylation.

327 Finally, we also investigated the role of the zinc-finger domain in nuclear translocation. The
328 chicken Sct2 zinc-finger domain has 61.47% identity to the homologous region in mouse Snail1
329 and was sufficient to promote nuclear localization Sct2. The nuclear shuttling function of mouse
330 Snail1 is attributed to importin binding to six basic and six hydrophobic residues [25]. Although
331 the zinc-finger domain in Sct2 contains all the six importin-binding hydrophobic residues, it lacks
332 one of the importin-binding basic residues identified in Snail1 (Fig. S4), indicating that
333 conservation of five of the basic residues is sufficient for nuclear localization. Also, the zinc-finger
334 domain is sufficient to direct protein-DNA interaction at E-box motifs (Fig. S5).

335 Thus, we confirm that Sct2, with a general structure similar to the Snail family members,
336 relies on SNAG for transcriptional repression and the zinc-finger domain for nuclear translocation
337 and DNA-binding. We also show that Sct2 has additional domains that modulate transcriptional
338 repression. Together, our data extends current knowledge on the modular structure of Snail
339 superfamily members and provides support for the hypothesis that modularity in this superfamily
340 arose from duplication and divergence from a common ancestral protein.

342 **Acknowledgements**

343

344 The authors thank Dr. Paulo Sérgio Lopes Oliveira for discussions about protein structure, Dr.
345 Cristóvão Albuquerque for editing assistance and Dr. Ali Brivanlou for generously sharing lab space and
346 reagents.

423

424 **Supporting information**

425 Supplementary figure 1

426 **Chicken Scrt2 localizes to the nucleus in chick neural tube cells.** Immunostaining of neural tube sections
427 show presence of MYC or FLAG tags in the nucleus 24 hours after electroporation with MYC-tagged
428 *cScrt2*WT (B) or FLAG-tagged *cScrt2*-Y77E (E) and *cScrt2*-S78A (H). MYC (B) and FLAG (E-H) signal
429 co-localizes with GFP (A, D, G) and DAPI (C, F, I). C', F' and I' are a higher magnification of the overlap
430 image in the dotted area in B, E and H. Vector reporter GFP labels the electroporated cells. Scale bar - 50
431 μm .

432 Supplementary figure 2

433 **HINGE and SCRATCH domains co-evolved in vertebrates and were both modified in fish.** (A) The
434 HINGE-SCRATCH region of different species was aligned to compare the changes in both domains

435 simultaneously. Conservation of the SCRATCH domain is higher amongst species that contain both
436 Tyrosine and a Serine in the HINGE domain. (B) Full length SCRT2 amino acid sequences were
437 aligned in CLUSTALX and the resulting N-J tree rooted with the wasp SCRT2 sequence. Python and Baiji
438 sequences were partial and lacked the SNAG domain.

439 Supplementary figure 3

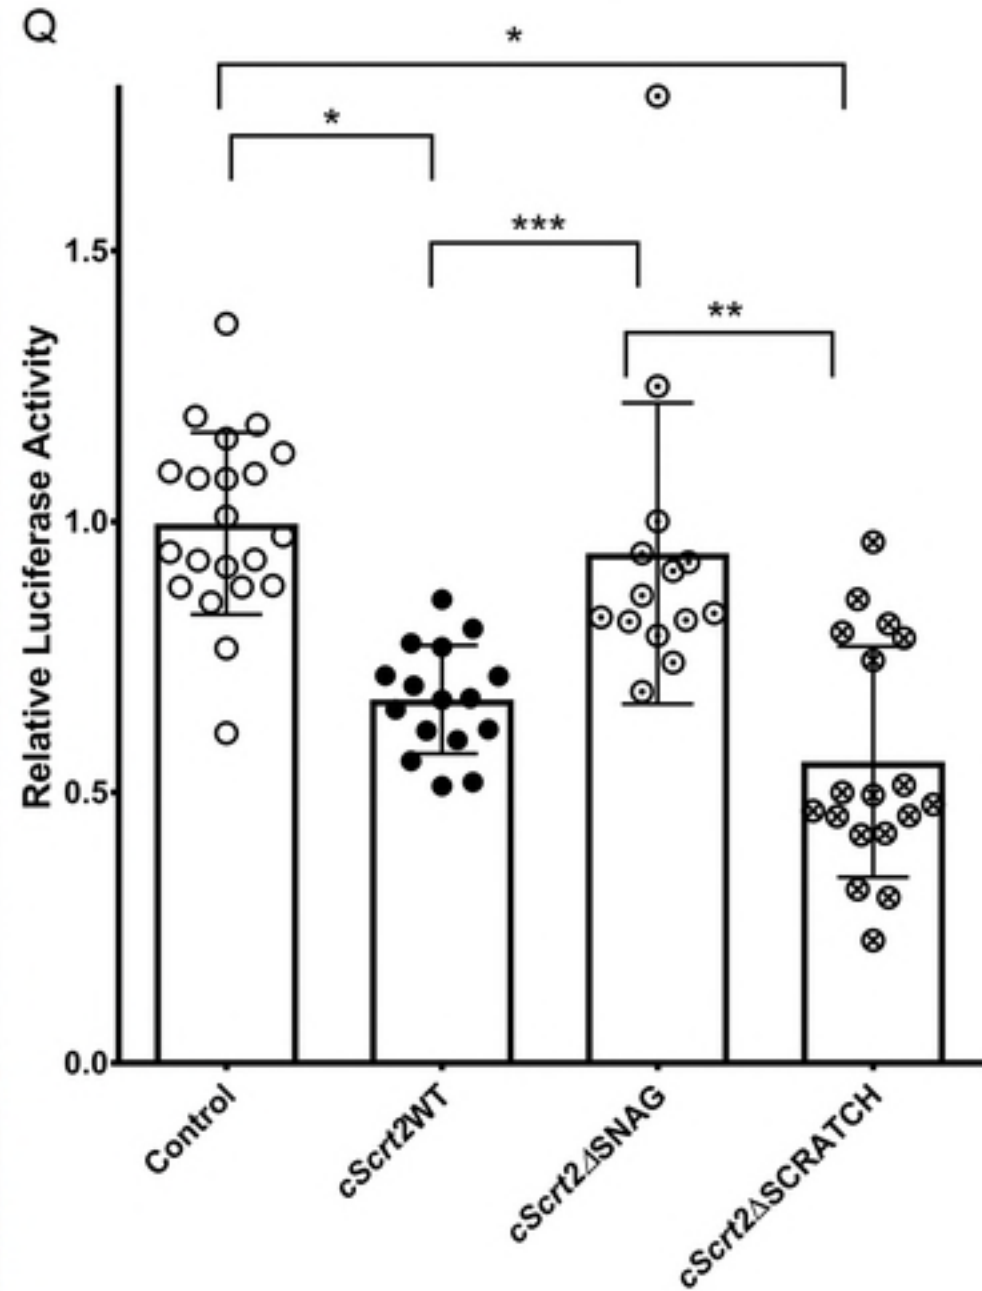

440 **Scrt2 has potentially phosphorylated residues.** *In silico* analysis of the chicken Scrt2 sequence using the
441 online phosphorylation prediction site KinasePhos identified residues Y77, S78 and S82 as possible targets
442 for phosphorylation. Below are candidate kinases for these phosphorylation sites. The box outlined in
443 dashed light blue lines shows the Scrt2-specific domain (aa 75-85 in chicken Scrt2).

444 Supplementary figure 4

445 **Alignment of the zinc-finger domains of selected members of the Snail superfamily.** ClustalW
446 alignment of the region containing zinc-fingers 2-4 of Snail and Scratch orthologues is shown here. The
447 residues that interact with importin are highlighted with different colors: basic residues are red and
448 hydrophobic residues are green. The labels are preceded by the species; h: human, m: mouse, c: chicken, d:
449 Drosophila. Sequences used were hSnail1 (NP_005976.2), hSnail2 (NP_003059.1), hScratch1
450 (NP_112599.2), hScrt2 (NP_149120.1), mSnail1 (NP_035557.1), mSnail2 (NP_035545.1), mScratch1
451 (NP_570963.1), mScrt2 (NP_001153882.1), cSnail1 (NP_990473.1), cSnail2 (CAA54679.1), cScrt2
452 (AEW43643.1), dSnail (NP_476732.1), dScratch (AAD38602.1).

453 Supplementary figure 5

454 **Chicken Sctr2 represses transcription driven by E-box.** HEK293T cells were transfected with pGL3-
455 4xE-box and empty pMES plasmid (Control), or full length Scrt2 (*cScrt2*WT) or Scrt2 zinc-fingers fused
456 to the repressor domain of Engrailed (EN-*Scrt2*) or to the VP16 activator domain (VP16-*Scrt2*). VP16-
457 *Scrt2* strongly enhanced transcriptional activity (t-test, $p < 0.001$) while *cScrt2*WT reduced transcription
458 below the basal levels (t-test, $p < 0.05$); EN-Scrt2-mediated reduction was not significantly different from
459 *cScrt2*WT.
