17

18 running headline = target-enrichment in minute wasps

19

20 **Abstract**

21 Enriching subsets of the genome prior to sequencing allows focusing effort on regions that are

22 relevant to answer specific questions. As experimental design can be adapted to sequence

23 many samples simultaneously, using such approach also contributes to reduce cost. In the

24 field of ecology and evolution, target enrichment is increasingly used for genotyping of plant

25 and animal species or to better understand the evolutionary history of important lineages

26 through the inference of statistically robust phylogenies. Limitations to routine target
27 enrichment by research laboratories are both the complexity of current protocols and low
28 input DNA quantity. Thus, working with tiny organisms such as micro-arthropods can be
29 challenging. Here, we propose easy to set up optimisations for DNA extraction and library
30 preparation prior to target enrichment. Prepared libraries were used to capture 1432 Ultra-
31 Conserved Elements (UCEs) from microhymenoptera (Chalcidoidea), which are among the
32 tiniest insects on Earth and the most commercialized worldwide for biological control
33 purposes. Results show no correlation between input DNA quantities (1.8-250ng, 0.4 ng with
34 an extra whole genome amplification step) and the number of sequenced UCEs. Phylogenetic
35 inferences highlight the potential of UCEs to solve relationships within the families of chalcid
36 wasps, which has not been achieved so far. The protocol (library preparation + target
37 enrichment), allows processing 96 specimens in five working days, by a single person,
38 without requiring the use of expensive robotic molecular biology platforms, which could help
39 to generalize the use of target enrichment for minute specimens.

40

41

42 **Key words** : Chalcidoidea, library construction, low DNA quantity, micro-arthropods, target
43 enrichment, UCEs.

44

45 INTRODUCTION

46 Enriching subsets of the genome prior to sequencing (target enrichment, Mamanova *et al.*
47 2010) allows effort to be concentrated on genomic regions that are relevant to answer specific
48 research questions. Using this approach also contributes to reducing cost, as experimental
49 design can be adapted to sequence many samples simultaneously. In the fields of ecology and
50 evolution, target enrichment has been used for genotyping or phylogenomics of plant and
51 animal species (Gasc *et al.* 2016; Lemmon & Lemmon 2013), to characterize phenotypic
52 traits (e.g., Muraya *et al.* 2015) or to explore microbial ecosystems (Gasc & Peyret 2018).
53
54 However, routine target enrichment by research laboratories is limited both by the complexity
55 of current protocols, and by input DNA quantity that may be very low for some minute
56 species (e.g. micro-arthropods < 1mm) and /or old /rare (museum) specimens. Indeed, current
57 protocols (DNA extraction, library preparation, target-enrichment) are time consuming and
58 require handling expertise. They have been initially developed to work with large amounts of
59 input DNA (e.g., vertebrates or large/medium size insects; Faircloth *et al.* 2015; McCormack
60 *et al.* 2013) and include many purification steps that increase DNA loss. Working on hyper-
61 diverse groups of microarthropods is challenging, as it requires one to perform the extraction
62 on i) a large number of specimens/species to be representative of the overall diversity of the
63 group, without the possibility of using pipetting robots that increase DNA loss, ii) single
64 individuals because species complexes are frequent (Al Khatib *et al.* 2014; Kenyon *et al.*
65 2015; Mottern & Heraty 2014), iii) the whole insect without destruction for vouchering and
66 often prior to species identification, iv) rare species that have been collected once and may be
67 represented in collection by a few specimens or only one specimen and, sometimes, v) old
68 and dry museum specimens used for species description (types).

69

70 In this study, we propose optimised protocols for DNA extraction and library preparation for
71 target enrichment purposes, as well as a custom pipeline to analyse the sequence data
72 obtained. We used these protocols and customised pipeline to capture and analyse Ultra
73 Conserved Elements (UCEs) in minute wasps, the chalcids (Insecta: Hymenoptera:
74 Chalcidoidea, Heraty *et al.* 2013; Noyes 2018), that are key components of terrestrial
75 ecosystems. Chalcids are key models for basic and applied research. With an estimated
76 diversity of more than 500,000 species these microhymenoptera have colonised almost all
77 extant terrestrial habitats. Many of them develop as parasitoids of arthropod eggs, larvae or
78 pupae. As such, they are both key regulators of the populations of many other arthropod
79 species in natural ecosystems and are increasingly used worldwide as biocontrol agents (e.g.,
80 Consoli *et al.* 2010; Heraty 2009). A few of them, especially *Nasonia* (Pteromalidae) or
81 *Trichogramma* (Trichogrammatidae) species are also used as model systems to answer
82 challenging questions about sex determination, genetics of speciation, host-symbiont
83 interactions or behavioural ecology (e.g., Pinto *et al.* 1991; Stouthamer *et al.* 1990; Werren &
84 Loehlin 2009). Chalcidoidea has undergone a spectacular radiation resulting in a huge
85 diversity of morphologies and sizes (Gibson *et al.* 1999; Heraty *et al.* 2013), but are generally
86 small insects (< 2 mm long). Among them, *Kikiki huna* Huber (Mymaridae) at 158 µm long is
87 the smallest winged insect currently known and the wingless male of *Dicopomorpha*
88 *echmepterygis* Mockford at 139 µm is the smallest insect currently known (Huber & Noyes
89 2013). Notably, most species used for biological control, belonging mainly to five families
90 (Aphelinidae, Encyrtidae, Eulophidae, Mymaridae and Trichogrammatidae) are among the
91 tiniest wasps on earth (< 1mm).

92

93 Their small size, huge diversity and widespread morphological convergence make chalcid
94 wasps difficult to identify to species by non-expert taxonomists, which limits their use in

95 biological control. Attempts have been made to resolve the phylogeny of the whole
96 superfamily (Heraty *et al.* 2013; Munro *et al.* 2011) or a few families (Burks *et al.* 2011;
97 Chen *et al.* 2004; Cruaud *et al.* 2012; Desjardins *et al.* 2007; Janšta *et al.* 2017; Owen *et al.*
98 2007) but none has succeeded. Indeed, the few markers that could be targeted with Sanger
99 sequencing were not informative enough to solve deeper relationships. A study based on
100 transcriptome data (3,239 single-copy genes) obtained from 37 species of chalcids and 11
101 outgroups also failed to solve relationships within the superfamily (Peters *et al.* 2018). As
102 only a representative sampling in both markers and taxa will allow one to draw accurate
103 conclusions on the history of this hyperdiverse group, target enrichment approaches appear
104 relevant. More specifically, targeting UCEs and their flanking regions that have been proven
105 useful to solve ancient and recent divergences (Faircloth *et al.* 2012; Smith *et al.* 2014) seems
106 pertinent. Indeed, a set of probes has been developed to target UCEs in Hymenoptera
107 (Faircloth *et al.* 2015). This set and an enriched one (Branstetter *et al.* 2017c) were
108 successfully used to solve the phylogeny of a few groups of ants, wasps and bees for which
109 the amount of DNA was not limiting (Blaimer *et al.* 2015; Blaimer *et al.* 2016a; Blaimer *et al.*
110 2016b; Bossert *et al.* 2017; Branstetter *et al.* 2017a; Branstetter *et al.* 2017b; Jesovnik *et al.*
111 2017; Prebus 2017; Ward & Branstetter 2017). Thus, contributing to the global effort to solve
112 the Hymenoptera tree of life while addressing the challenge of the phylogeny of chalcid
113 wasps seemed sound.

114

115 Here, we provide a detailed description of the optimised protocol for DNA extraction and
116 library preparation, followed by a description of the phylogenetic trees obtained through
117 target enrichment of UCEs from 96 species belonging to seven families and one subfamily of
118 chalcids used for biological control (Aphelinidae, Azotidae, Encyrtidae, Eulophidae,
119 Mymaridae, Pteromalidae: Eunotinae, Signiphoridae, Trichogrammatidae) as well as three

120 outgroups in Mymaromatidae, the putative sister group to Chalcidoidea (Gibson *et al.* 2007;
121 Heraty *et al.* 2013).

122

123 **MATERIALS AND METHODS**

124

125 **Sampling**

126 Samples were taken from the personal collections of the co-authors of this paper, or borrowed
127 from the Queensland Museum (Australia) or the Australian National Insect Collection,
128 Canberra. Details of the samples included in the analysis are presented in Table S1. Most
129 specimens sampled in the field were placed directly into ethanol for storage. On average,
130 specimens spent 3.5 years in ethanol before being processed (maximum storage time in
131 alcohol = 34 years). Two specimens were critical point dried 25 or 34 years ago. UCE data for
132 three specimens were retrieved from a previous study (Branstetter *et al.* 2017a): *Euplectrus*
133 sp. (empirical data); *Copidosoma floridanum* and *Trichogramma pretiosum* (*in silico*
134 extraction of UCEs from genomes).

135

136 **DNA extraction**

137 DNA was extracted using the Qiagen DNeasy Blood and Tissue kit. All extractions were
138 conducted without destruction of the specimens' external (and certain internal) structures,
139 with digestion and lysis of just the soft tissues. In this way, actual or potential type specimens
140 are preserved. An often-essential feedback to the morphology is also preserved which is
141 critical in this difficult group. The following modifications were made to manufacturer's
142 protocol. Samples were incubated overnight in an Eppendorf thermomixer (temperature =
143 56°C, mixing frequency = 300 rpm). To increase DNA yield, two successive elutions (50 µL
144 each) were performed with heated buffer AE (56°C) and an incubation step of 15 minutes

145 followed by centrifugation (8000 rpm for 1 minutes at room temperature). Eppendorf
146 microtubes LoBind 1,5ml were used for elution and to store DNA at -20°C until library
147 preparation. DNA was quantified with a Qubit® 2.0 Fluorometer (Invitrogen). The final
148 version of the DNA extraction protocol is available as an additional file 1. Vouchers were
149 deposited at CBGP, Montferrier-sur-Lez, France or returned to their owner.

150

151 **Whole genome amplification**

152 DNA extracted from two specimens was subjected to ethanol precipitation and whole genome
153 amplification (WGA) using the GenomiPhi™ V2 DNA Amplification kit (GE Healthcare) as
154 described in Cruaud *et al.* (in press). 1µl of concentrated DNA was used as input (i.e. 4 ng or
155 0.4 ng, Table S1).

156

157 **Library preparation.**

158 Our starting point was the protocol described in <http://ultraconserved.org> and Faircloth *et al.*
159 (2015). The final goal was to obtain a standardized protocol that could be implemented by one
160 person and which, in 5 working days, would made possible the manual preparation of
161 libraries and the capture of UCEs from 96 samples in parallel. Steps by steps optimisations
162 were made specially to remove time-consuming purification steps and different reagents were
163 tested. The final version of the protocol is available as additional file 2. Briefly, input DNA
164 was sheared to a size of ca 400 bp using the Bioruptor® Pico (Diagenode). End repair, 3'-end
165 adenylation, adapters ligation and PCR enrichment were then performed with the NEBNext
166 Ultra II DNA Library prep kit for Illumina (NEB). We used barcoded adapters that contained
167 amplification and Illumina sequencing primer sites, as well as a nucleotide barcode of 5 or 6
168 bp long for sample identification (additional file 3). Pools of 16 samples were made at
169 equimolar ratio. We enriched each pool using the 2749 probes designed by Faircloth *et al.*

170 (2015) using MYbaits kits (MYcroarray, Inc.). We followed manufacturer's protocol
171 (MYbaits, user manual version 3, <http://www.mycroarray.com/pdf/MYbaits-manual-v3.pdf>).
172 The hybridization reaction was run for 24h at 65°C. Post enrichment amplification was
173 performed on beads with the KAPA Hifi HotStart ReadyMix. The enriched libraries were
174 quantified with Qubit, an Agilent Bioanalyzer and qPCR with the Library Quantification Kit -
175 Illumina/Universal from KAPA (KK4824). They were then pooled at equimolar ratio. Paired-
176 end sequencing (2*300bp) was performed on an Illumina Miseq platform at UMR AGAP
177 (Montpellier, France) to get longer flanking regions and, as a consequence, more information
178 to differentiate closely related species.

179

180 **Raw data cleaning**

181 The analytical workflow is summarized in figure S1. In the next paragraph, chosen parameter
182 values (different from default value) are provided between parentheses. Quality control
183 checks were performed on raw sequence data with FastQC v.0.11.2 (Andrews 2010). Quality
184 filtering and adapter trimming were performed with Trimmomatic-0.36 (Bolger *et al.* 2014)
185 (LEADING:20 TRAILING:20 SLIDINGWINDOW:4:20 MINLEN:180, with PrefixPE/1=
186 AATGATACGGCGACCACCGAGATCTACACTCTTTCCCTACACGACGCTCTTCCGA
187 TCT and PrefixPE/2 =
188 CAAGCAGAAGACGGCATAACGAGATCGGTCTCGGCATTCCTGCTGAACCGCTCTTC
189 CGATCT). Overlapping reads were merged using FLASH-1.2.11 (-M 300) (Magoc &
190 Salzberg 2011). Demultiplexing was performed using a bash custom script (no mismatch in
191 barcode sequences was allowed, additional file 4). Assembly of cleaned reads was performed
192 using CAP3 (-i 25 -o 25 -s 400) (Huang & Madan 1999). The 2749 probes designed by
193 Faircloth *et al.* (2015) were assembled into non-overlapping UCEs (hereafter called reference
194 UCEs, n=1432, additional files 5 and 6) using Geneious 8.1.8 (Kearse *et al.* 2012) and contigs

195 were aligned to this set of reference UCEs using LASTZ Release 1.02.00 (Harris 2007).
196 Contigs that aligned with more than one reference UCE and different contigs that aligned with
197 the same reference UCE were filtered out using Geneious 8.1.8.

198

199 **Data analysis**

200 UCEs for which sequences were available for more than 25% of the taxa were kept in the next
201 steps of the analysis. Alignments were performed with MAFFT v7.245 (Katoh & Standley
202 2013) (-linsi option). Ambiguously aligned blocks were removed using Gblock_0.91b with
203 relaxed constraints (-t=d -b2=b1 -b3=10 -b4=2 -b5=h) (Talavera & Castresana 2007). The
204 final data set was analysed using supermatrix approaches and coalescent-based summary
205 methods. Two gene tree reconciliation approaches were used: ASTRAL-III v5.6.1 (Zhang *et*
206 *al.* 2018), which computes the phylogeny that agrees with the largest number of quartet trees
207 induced by the set of input gene trees and ASTRID (Vachaspati & Warnow 2015) which
208 takes a set of gene trees, computes a distance matrix (*ca* sum of number of edges in the path
209 between two samples divided by the number of gene trees in which the two samples are
210 represented) and infers a phylogeny from this distance matrix. Following recommendations
211 for incomplete distance matrices, BioNJ was used to compute the phylogeny. Individual trees
212 were inferred from each UCE using raxmlHPC-PTHREADS-AVX (Stamatakis 2014)
213 (version 8.2.4; -f a -x 12345 -p 12345 -# 100 -m GTRGAMMA). ASTRAL and ASTRID
214 analyses were performed with 100 multi-locus bootstrapping (MLBS, site-only resampling
215 (Seo 2008)). Phylogenetic trees were estimated from the concatenate, unpartitioned data set
216 using Maximum Likelihood (ML) approaches as implemented in RAxML and IQTREE
217 v1.6.4 (Nguyen *et al.* 2015). For the RAxML analysis, a rapid bootstrap search (100
218 replicates) followed by a thorough ML search (-m GTRGAMMA) was performed. For the
219 IQTREE analysis, a ML search with the best-fit substitution model automatically selected was

220 performed with branch supports assessed with ultrafast bootstrap (Minh *et al.* 2013) and SH-
221 aLRT test (Guindon *et al.* 2010) (1000 replicates).

222 Summary statistics for all data sets (alignment length, number of samples, number of variable
223 sites, number of parsimony informative sites etc.) were calculated using AMAS (Borowiec
224 2016). Tree annotation was performed with TreeGraph 2.13 (Stöver & Müller 2010).

225 Linear correlation between the number of UCEs and the quantity of DNA used to build the
226 library was tested with the Pearson's correlation coefficient in R (R Core Team 2015).

227 Analyses were performed on a Dell PowerEdge T630 with 10 Intel Xeon E5-2687 dual-core
228 CPUs (3.1 GHz, 9.60 GT/s), 125 Go RAM and 13 To hard drive and on the Genotoul Cluster
229 (INRA, Toulouse).

230

231 **RESULTS**

232 Optimisations made for DNA extraction are detailed in the additional file 1. The final version
233 of the library preparation protocol is available as additional files 2 and 3. Hereafter, the range
234 of values provided between parentheses refers to the range of data that fall between the 2.5th
235 percentile (LB=lower bound) and 97.5th percentile (UP = upper bound). Table S1 contains
236 sequencing information for all samples. The median amount of input DNA was 25ng
237 (LB=1.8ng; UP=250ng). An average of 76,330 reads (cleaned and merged) per sample was
238 obtained (LB=3,359; UP=348,326). The average number of contigs was 3,454 (LB=546;
239 UP=14,012) and the average sequencing depth was 18X (LB=3X; UP=44.0X). The average
240 number of UCEs obtained per sample after filtering of problematic contigs was 687 (LB=193-
241 UP=1,082) with a length comprised between LB=315 and UP=816bp (mean=603bp).

242 Figure 1 and S2 show the variation of the number of UCEs obtained with regard to the
243 amount of input DNA. No significant correlation was observed (Pearson's correlation
244 coefficient = 0.096, p-value = 0.36).

245 The final dataset (25%-complete matrix; i.e. at least 25 taxa on the 99 should have a sequence
246 to keep the locus in the analysis) comprised 1,139 UCEs and 340,286bp (missing data = 47.0
247 %; parsimony informative sites = 72.3 %; GC-content = 42.6%).
248 Specimens retrieved from a previous study (Branstetter *et al.* 2017a) that were either
249 represented by empirical data (*Euplectrus* sp.) or UCEs extracted from published genomes
250 (*Copidosoma floridanum* and *Trichogramma pretiosum*) displayed a number of UCEs
251 comparable to what was obtained for other specimens. Their placement in the trees (Figures
252 2; S3-S5) was in accordance with their morphology. Whatever the method used (supermatrix
253 approaches versus coalescent-based summary methods), all families, except for Aphelinidae,
254 were recovered as monophyletic with high support. Aphelinids were split into three groups: 1)
255 a monophyletic Aphelininae + Eretmocerinae; 2) Coccophaginae; 3) *Cales* sp. (Calesinae).
256 The position of *Cales* was ambiguous. *Cales* was either recovered as sister to
257 Trichogrammatidae (RAxML, low support) or as a lineage distinct from all other chalcidooids
258 (all other analyses). Except for Mymaridae that was strongly placed as sister to all other
259 Chalcidoidea in all analyses, the tree backbone remained poorly resolved. Statistical support
260 was much higher within families. In all analyses Azotidae clustered with Signiphoridae, with
261 strong support.

262

263 **DISCUSSION**

264 To our knowledge this study is the second after Sproul and Maddison (2017) to demonstrate
265 success in library preparation from such low input using commercial kits, and the first to
266 report successful sequencing of >1000 low copy genes in 96 specimens in parallel, from such
267 low input and processing time. Our optimisations differ from what was proposed by Sproul
268 and Maddison (2017). First, we tried to optimize DNA extraction itself by using overnight
269 lysis with gentle mixing to preserve fragile specimens, heated elution buffer and increased

270 incubation time before elution. Second, instead of increasing the number of time-consuming
271 purification steps we decreased them. It is noteworthy that in this library only two historical
272 specimens were included. This may have masked challenges posed by adapter dimers (Burrell
273 *et al.* 2015; Sproul & Maddison 2017; Tin *et al.* 2014) that led Sproul and Maddison (2017) to
274 add a second bead clean-up prior to library amplification. However, we have already used this
275 protocol on hundreds of chalcid and moth species, including historical specimens that were
276 processed the same way as fresh ones and we never had such an issue. Finally, instead of
277 increasing the number of amplification cycles prior to target enrichment, we used a new
278 generation mastermix including a hot start, processive and high-fidelity polymerase
279 (NEBNext Ultra II Q5 Master Mix). Our protocol also allows one to back-up DNA at several
280 steps that allows for multiple attempts without delay in case the first attempt fails. Finally,
281 sequencing was performed on a MiSeq to get longer flanking regions and, as a consequence,
282 more information to differentiate closely related species.

283

284 The protocol was successfully used on minute chalcid wasps widely used for biological
285 control purposes. Up to 1165 valid UCEs were captured from 25ng DNA (median amount of
286 DNA used for this study). No correlation was observed between the quantity of DNA used for
287 library preparation and the number of captured UCEs. The average number of captured UCEs
288 validated by our quality control workflow was 687, and 685 valid UCEs were captured from a
289 tiny aphelinid (1.8ng of input DNA). The number of UCEs obtained per individual appears to
290 drop within the basal clades (i.e., Mymaridae and Trichogrammatidae, Figure S2), a result
291 probably linked to the relatively long branches observed in these groups, and that could
292 reduce the efficiency of the probes that were designed from the genome of *Nasonia* (Faircloth
293 *et al.* 2015). Trees were well resolved at the family level, with high statistical support,
294 showing the potential of UCEs to solve long-standing taxonomic issues. However, the tree

295 backbone remained unresolved, a pattern that confirms the rapid diversification of the group
296 (Heraty *et al.* 2013; Peters *et al.* 2018). Understanding the evolutionary history of the group
297 was not the purpose of this paper. Indeed, only a representative sampling in both markers and
298 taxa as well as cutting-edge data analysis will allow drawing accurate conclusions. By
299 providing suitable tools for a fast, easy and affordable acquisition of data, this paper is a first
300 step.

301

302 Interestingly, as it has been shown previously on RADseq data (Cruaud *et al.* in press), WGA
303 does not seem to bias the results even when input DNA used for the WGA is below the
304 recommendation on the manufacturer kit (here 0.4 and 4 ng when the Genomiphi kit V2
305 requires 10 ng). This further increases the possibilities opened by our protocol as input DNA
306 as low as 0.2-0.3 ng may be used when an extra WGA step is included after DNA extraction
307 (Cruaud *et al.* in press). It is noteworthy that reducing the amount of DNA required for library
308 preparation allows one to use extracted DNA for different approaches in parallel (RADseq,
309 amplicon, Shotgun etc.). This also allows one to send DNA back to museums from which
310 specimens were borrowed, for archival purposes. We definitely agree with Sproul and
311 Maddison (2017) who emphasize how important it is not to waste DNA obtained from
312 irreplaceable specimens (whether fresh or historical). It is even more important to capitalize
313 on existing collections as collecting samples for large-scale studies may be more and more
314 difficult, given that many countries have imposed restrictive access regulations, even to
315 academic researchers, to reduce the risk of supposed biopiracy (Divakaran Prathapan *et al.*
316 2018).

317

318 All the elements discussed above indicate that this protocol may be of great help to
319 reconstruct phylogenetic hypotheses in multiple groups of tiny arthropods, e.g., springtails,

320 sandflies, lice, whiteflies, mites, etc. Coupled or not with WGA, some steps of our protocol
321 may also contribute to simplify and hasten construction of other reduced-representation
322 libraries (RAD-Seq, ddRAD-Seq, etc). These methods may then be used to analyse species
323 relationships, hybridization or population genomics (Cruaud *et al.* 2014; Eaton & Ree 2013;
324 Emerson *et al.* 2010; Gagnaire *et al.* 2013; Hipp *et al.* 2014) on minute arthropods or on
325 endangered species using non-invasive DNA sampling (Vila *et al.* 2009).

326

327

328 **ACKNOWLEDGEMENTS**

329 We are grateful to Nicole Fisher (CSIRO, National Museum of Australia, Canberra), Chris
330 Burwell, Christine Lambkin and Susan Wright (Queensland Museum, Brisbane, Australia) for
331 facilitating access to samples and to the Genotoul bioinformatics platform Toulouse Midi-
332 Pyrenees, France for providing computing resources. AC thanks Lisa Schlée, Philippe Cruaud
333 and Maya for their patience in the field and Jean-Pierre Rossi for his help with R. AG thanks
334 V. Fursov (Schmalhausen Institute of Zoology, Ukraine) for his help with specimen
335 identification. This work is part of a large NSF project (Award#1555808) led by John Heraty
336 (UC Riverside USA) that attempts to solve the phylogeny of Chalcidoidea with NGS
337 approaches, and was partly funded by the ANR project TriPTIC (ANR-14-CE18-0002) led by
338 JYR and the SPE department of the INRA (French National Agronomic Institute). LF travels
339 to France were supported by the grants IntegPar (89BM/2017) and NEVPIT (PN-III-P4-ID-
340 PCE-2016-0233) awarded by the Romanian National Authority for Scientific Research,
341 CNCS – UEFISCDI. This paper is dedicated to the memory of our friend Dr John La Salle,
342 whose kindness and sense of humor will be remembered for ever.

SH-aLRT / UFboot values are indicated at nodes.

The DNA quantity used to build the library as well as the number of UCEs analysed for each sample is given in brackets.

Figure S4 ASTRAL tree obtained from the analysis of the 25%-complete data set (page 139) Bootstrap supports (site-only resampling) are indicated at nodes. The DNA quantity used to build the library as well as the number of UCEs analysed for each sample is given in brackets.

Figure S5 ASTRID tree obtained from the analysis of the 25%-complete data set (page 140) Bootstrap supports (site-only resampling) are indicated at nodes. The DNA quantity used to build the library as well as the number of UCEs analysed for each sample is given in brackets.

Additional file 1: Optimized protocol for DNA extraction

Optimisations were done to the DNeasy Blood & Tissue Kit (250) protocol (Qiagen)

Consumables

Tweezers and fine brush/or forceps to manipulate specimens; 1 pot with bleach at a 1:10 dilution with osmosis cleaned water; 1 pot with osmosis cleaned water to wash tweezers/forceps, cup, paper towels, sterile gloves, 50ml Falcon™ tube, 1.5ml Safe-lock tubes (Eppendorf), 1,5ml Microtubes DNA LoBind (Eppendorf).

-----day 1 / afternoon-----

- Label 1.5ml safe-lock tubes with sample codes. Close caps. Put under UV light for 10 min.
- Equilibrate frozen specimens to room temperature before processing.
- Dry specimens on clean paper towel to remove EtOH. Place specimen in tube. Clean forceps to avoid contamination between 2 different specimens: bleach, then water, then dry with paper towel.
- Add 200µl buffer ATL (Qiagen) to each tube.
(NB DNeasy® Blood & Tissue Handbook uses 180µl; we use 200µl to improve diffusion of the DNA from the specimen)
- Add 20µl proteinase K to each tube (or prepare a master mix of buffer ATL + proteinase K and add master mix to tubes.)
- Vortex + Pulse spin.
(NB if the specimens are fragile, i.e. old and dry mounted collection specimens, dispense the master mix of buffer ATL + proteinase K to each tube and then add specimens; or dispense specimens to tubes and then add the master mix. Do not vortex at all to avoid damage to specimens and place the tubes directly in the thermomixer after ensuring that the specimens are in the liquid.)
- Place tubes in thermomixer (Eppendorf) at 56°C and 300 rpm overnight.

-----day 2 / morning-----

- Remove tubes from thermomixer.
- Vortex + pulse spin.
(NB if working with fragile specimens do not vortex. Pulse spin, transfer all the liquid to a new labelled tube leaving the specimen behind and then proceed to the next step.)

(DNeasy® Blood & Tissue Handbook, p. 15, recommends using carrier DNA or RNA for samples containing less than 5 µg of DNA. Though this was not used for this publication, poly (A) RNA (2 µl of 2 µg/µl) is added to the lysate before the next step by one of us (LF) for routine DNA purification from small or old specimens. This should not interfere with library preparation as it was used for example by Sproul & Maddison (2017) as recommended in the QIAamp DNA Micro Kit by Qiagen.)

- Add 200µl buffer AL to each tube (kit Qiagen). (DNeasy® Blood & Tissue Handbook, p. 19, 29 recommends adding RNase A if RNA-free genomic DNA is required. We do not use it because the copurified RNA is not interfering with target enrichment anyway and because RNase A also degrades DNA; see Donà & Houseley (2015).)

A white precipitate may appear that will dissolve during incubation at 70°C.

- Vortex + pulse spin.
- Incubate tubes in thermomixer at 70°C and 300 rpm for 10 minutes.
- During that time, prepare DNeasy mini spin Qiagen columns and 1.5 ml DNA LoBind Eppendorf tubes (label tubes with sample codes). (NB LoBind tubes minimize DNA loss during storage by reducing sample-to-surface binding.)

- Aliquot buffer AE in Eppendorf tubes and heat at 56°C in thermomixer (heated buffer will improve the release of DNA from the resin.)

- Add 200µl absolute ethanol (not provided with the Qiagen kit) to each tube. (NB only high purity ethanol should be used; cheap ethanol may contain traces of other chemicals that will interfere with the solubilisation of the DNA from the membrane in the last step.)

- Vortex + Pulse spin.
- Pipette the liquid (including precipitate) from each tube and transfer into a DNeasy mini spin Qiagen column placed in a 2 ml collection tube (Qiagen kit).
- Centrifuge columns + collection tubes at 6000 x g (8000 rpm) for 1 minute; discard the flow-through and collection tubes. Keep the columns.
- Place spin columns in new collection tubes.
- Add 500µl buffer AW1 (kit Qiagen).
- Centrifuge at 6000 x g (8000rpm) for 1 minute; discard the flow-through and collection tubes. Keep the columns.
- Place spin columns in new collection tubes.
- Add 500µl buffer AW2 (kit Qiagen).
- Centrifuge at 20,000 x g (14,000 rpm) for 3 minutes to dry the columns.
- Rotate columns to 180 degrees in their collection tubes and centrifuge again at 20000 xg (14000rpm) for 3 minutes (this will make sure the column is well dried).
- Place dried spin columns in 1.5ml LoBind tubes that you previously labelled.
- Add 50µl of heated AE buffer. **Deposit buffer right in the middle of the resin.**
- Incubate 15 min at room temperature (**meanwhile, reheat buffer AE.**)
- Centrifuge at 6000 x g (8000 rpm) for 1 minute.
- Rotate columns to 180 degrees and centrifuge again at 6000 x g (8000 rpm) for 1 minute.
- Remove columns + tubes from the centrifuge.
- Add again 50µl of heated buffer **right in the middle of the resin.**
- Incubate 15 min at room temperature.
- Centrifuge at 6000 x g (8000 rpm) for 1 minute at room temperature.
- Rotate columns to 180 degrees and centrifuge again at 6000 x g (8000 rpm) for 1 minute.
- DNA (ca 2 x 50µl) is ready for use.

- Add distilled water to the extracted specimens and incubate at room temperature for 30 min.

(NB water is used to eliminate the residual salts left by the buffers. Otherwise they usually crystallise on the specimen upon storage in ethanol.)

- Remove water and replace with ethanol. Keep specimens in the dark in a freezer until mounting.

(NB if the specimens are stored at room temperature under ambient light they will become sun-bleached very quickly, much quicker than unextracted specimens.)

- Use a critical point dryer, hexamethyldisilazane, acetone or amyl acetate to dry the specimens before mounting. Do not air dry as they will collapse.

Additional file 2: Optimized protocol for library preparation

1. DNA quantification

Qubit® 2.0 Fluorometer (Invitrogen); dsDNA HS Assay Kit.

2. DNA normalization and shearing

Bioruptor ® Pico, sonication bath-based rotor 12 samples in parallel.

Transfer 100µl of input DNA in tubes adapted to the Bioruptor ® Pico that will be used for DNA shearing (Diagenode tubes 0.5ml). [now we shear 30ng DNA in routine but you can use as little as 1.8 ng, see main text]

Set up the following program for DNA shearing to obtain a mean fragment size of ca 400pb:

15sec ON / 90sec OFF for 8 cycles.

You can STOP here for up to 1 week (store tubes in a freezer at -20°C).

The NEBNext Ultra II DNA Library prep kit for Illumina by NEB will be used for End repair, A tailing, Adapter ligation and PCR enrichment of adaptor-ligated DNA.

3. End repair + A tailing

To keep a backup, only 50 µl of the sheared DNA is used [you may want to re-concentrate DNA on beads in 50 µl when you have a small amount i.e. < 5 ng]

Transfer 50 µl of sheared DNA into a strip / plate.

Thaw NEBNext Ultra II End Prep Reaction Buffer. Vortex + pulse spin.

ATTENTION: Pull out NEBNext Ultra II End Prep Enzyme Mix out of freezer just before use. LIGHT vortex + pulse spin.

	Master Mix:	x1 reaction	x 96 reactions
NEBNext Ultra II End Prep Enzyme Mix		3 µl	288 µl
NEBNext Ultra II End Prep Reaction Buffer		7 µl	672 µl
Master mix to add to each tube		10 µl	

Vortex master mix gently + pulse spin.

- Add 10µl of master mix to tubes containing 50µl of sheared DNA.
- Vortex (**mix well.**)
- Pulse spin.
- Place in a thermocycler. **Enable heated lid** and run the following program:
 - 30 min at 20°C**
 - 30 min at 65°C**
 - Hold at 4°C.**

PROCEED WITHOUT DELAY TO ADAPTER LIGATION

4. Adapter ligation and cleanup

See **additional file 3** for adapter sequences and hybridization.

Thaw adapters (1.5µM). Centrifuge to avoid cross contamination. Open carefully.

For 96 samples use the following tagging scheme:

P1-1	P1-9	P1-1	P1-9	P1-1	P1-9	P1-1	P1-9	P1-1	P1-9	P1-1	P1-9
P1-2	P1-10	P1-2	P1-10	P1-2	P1-10	P1-2	P1-10	P1-2	P1-10	P1-2	P1-10
P1-3	P1-11	P1-3	P1-11	P1-3	P1-11	P1-3	P1-11	P1-3	P1-11	P1-3	P1-11
P1-4	P1-12	P1-4	P1-12	P1-4	P1-12	P1-4	P1-12	P1-4	P1-12	P1-4	P1-12
P1-5	P1-13	P1-5	P1-13	P1-5	P1-13	P1-5	P1-13	P1-5	P1-13	P1-5	P1-13
P1-6	P1-14	P1-6	P1-14	P1-6	P1-14	P1-6	P1-14	P1-6	P1-14	P1-6	P1-14
P1-7	P1-15	P1-7	P1-15	P1-7	P1-15	P1-7	P1-15	P1-7	P1-15	P1-7	P1-15
P1-8	P1-16	P1-8	P1-16	P1-8	P1-16	P1-8	P1-16	P1-8	P1-16	P1-8	P1-16
P2-1		P2-2		P2-3		P2-4		P2-5		P2-6	

Thaw NEBNext Ultra II Ligation master mix. Light vortex + Pulse spin.

Thaw NEBNext Ligation enhancer. Light Vortex + pulse spin.

	Master Mix:	
	x1 reaction	x 96 reactions
NEBNext Ultra II Ligation master mix	30 µl	2880 µl
NEBNext Ligation enhancer	1 µl	96 µl
Master mix to add to each tube	31 µl	

Vortex (mix well) + pulse spin

- Add 31 µl of master mix to tubes containing the 60 µl end prep reaction mixture obtained in the previous step.
- Add 1.25 µl of P1 adapters (1.5µM) and 1.25 µl of P2 adapters (1.5 µM) to each tube.
- Vortex (**mix well.**)
- Pulse spin.
- Place in a thermocycler. **Disable heated lid** and run the following program:
15 min at 20°C.

(NB samples can be stored overnight at -20°C.)

Clean-up adaptor ligated DNA (remove dimers of adapters):

Purification was conducted with the Agencourt AMPure XP Purification system (Beckman Coulter) and a ALPAQUA magnet plate.

Pull Ampure beads out of fridge. Make sure they are at room temperature (RT) before use.

- Vortex Ampure beads.
- Add 0.8 vol. of Ampure beads for 1 vol. of DNA (i.e. 74.8 µl of beads for 93.5 µl of DNA => vol. tot. = 168.3 µl).

- Vortex + pulse spin.
- Incubate for **5min** at RT.
- Move strip to magnetic rack and wait for **2 to 5min**.
- Remove and discard supernatant without disturbing beads.
- Do not remove tubes from magnetic rack and add **200 µl of 70 % ethanol** without disturbing beads (use freshly made 70% ethanol to ensure accurate concentration.)
- Wait for **30s** (leave cap open.)
- Remove and discard supernatant without disturbing beads.
- Add again **200 µl of 70 % ethanol**.
- Wait for **30s** (leave cap open.)
- Remove and discard supernatant without disturbing beads.
- **Make sure to remove all traces of ethanol** (use a 10µl micropipette if necessary.)
- Dry for **5 min** (leave cap open.)
- Do not remove tubes from magnetic rack and add **15µl of buffer EB**.
- Close cap.
- Remove strip from magnetic rack.
- Vortex + pulse spin.
- Wait for **2min**.
- Move strip back to magnetic rack and wait for **2 to 5min**.
- Transfer the **15µl** of DNA to a new strip.

5. PCR enrichment of adaptor-ligated DNA

Thaw NEBNext Ultra II Q5 Master Mix. Homogenize by pipetting + Pulse spin. DO NOT VORTEX. Leave on Ice.

	Master Mix:	
	x 1 reaction	x 96 reactions
NEBNext Ultra II Q5 Master Mix	25 µl	2400 µl
Primer F (10µM)	2 µl	192 µl
Primer R (10µM)	2 µl	192 µl
Master mix to add to each tube	29 µl	

With

Primer F = AATGATACGGCGACCACCG*A

Primer R = CAAGCAGAAGACGGCATAACG*A

(synthesized by IDT (Integrated DNA Technologies, Inc.), HPLC Purification, * = Phosphorothioate Bond.)

Vortex + pulse spin master mix

- Add 29 µl of master mix to tubes containing the 15 µl of adaptor ligated DNA.
- Vortex.
- Pulse spin.
- Place in a thermocycler. **Enable heated lid** and run the following program:

	15 cycles				
Time	30s	10s	75s	5min	∞
Temperature	98°C	98°C	65°C	65°C	4°C

6. Quantification, equimolar pooling and re-concentration

Qubit - quantify 2 μ l of each library.

In our experience, a clean-up step of the libraries is not necessary.

Prepare 6 pools of 16 samples in 1.5ml LoBind tubes.

Pool 100 ng of each library (you want a final quantity of 100-500ng DNA per pool after concentration to fit with the requirements of the MYbaits® protocol.)

On beads Concentration of DNA (Agencourt AMPure XP Purification system (Beckman Coulter)). Concentration of DNA is required, as MyBaits require 7 μ l of starting material.

Remove Ampure beads from fridge. Make sure they are at room temperature (RT) before use.

- Vortex Ampure beads.
- Add 0.8 vol. of Ampure beads for 1 vol. of DNA.
- Vortex + pulse spin.
- Incubate for **5min** at RT.
- Move tubes to magnetic rack and wait for **2 to 5 min**.
- Remove and discard supernatant without disturbing beads.
- Do not remove tubes from magnetic rack and add **200 μ l of 70 % ethanol** without disturbing beads (use freshly made 70% EtOH to ensure accurate concentration.)
- Wait for **30s** (leave cap open.)
- Remove and discard supernatant without disturbing beads.
- Add again **200 μ l of 70 % ethanol**.
- Wait for **30s** (leave cap open.)
- Remove and discard supernatant without disturbing beads.
- **Make sure to remove all traces of Ethanol** (use a 10 μ l micropipette if necessary.)
- Dry for **5 min** (leave cap open.)
- Do not remove tubes from magnetic rack and add **9 μ l** of buffer EB.
- Close cap.
- Remove tubes from magnetic rack.
- Vortex + spin pulse.
- Wait for **2min**.
- Move strip back to magnetic rack and wait for **2 to 5min**.
- Transfer the **9 μ l** of DNA to a new 1.5ml LoBind tube.

Qubit quantify 1 μ l of each library (dilution 1:2).

Check library profile on an Agilent Bioanalyzer with a High Sensitivity DNA Analysis Kit (load 1 μ l of library dilution 1:2).

7. Capture of UCEs

UCEs were captured on each pool using the probes designed by Faircloth et al. (2015) and synthesized by MYbaits®. Capture was performed with the MYbaits® kit following manufacturer's instruction (<http://www.mycroarray.com/pdf/MYbaits-manual-v3.pdf>).

8. PCR Enrichment of captured libraries and final clean-up

At this step of the process we have obtained libraries and Streptavidin beads mixed in 30 μ l of 10mM Tris-Cl, 0.05% TWEEN®-20 solution (pH 8.0 – 8.5).

Here we want to release the bead-bound UCE-enriched library from the baits and amplify the resulting fragments.

PCR enrichment of the captured fragment is performed on beads with the following mix. We performed 2 PCR reactions for each pool of samples.

Post-capture PCR Master Mix:	Final concentration	x1
H2O up	-	5 μ l
2X KAPA Hifi HotStart ReadyMix	1X	25 μ l
Primer F (10 μ M)	500nM	2.5 μ l
Primer R (10 μ M)	500nM	2.5 μ l
Enriched Library (on-bead)	-	15 μ l
Master mix to add to each well		50 μ l

With

Primer F = AATGATACGGCGACCACCG*A

Primer R = CAAGCAGAAGACGGCATAACG*A

(synthesized by IDT (Integrated DNA Technologies, Inc.), HPLC Purification, * = Phosphorothioate Bond)

Program:	14 cycles					
Step	Activation	Denaturation	Annealing	Extension	Final Extension	End
Time	2min	20sec	30sec	45sec	5min	∞
Temperature	98°C	98°C	65°C	72°C	72°C	10°C

Remove Streptavidin beads:

Pool the 2 PCR products obtained for each pool of samples in DNA LoBind tubes (1.5ml.)
Move the 6 tubes to a magnetic rack and wait for 2 to 5min.
Transfer supernatant to new tubes.

Final Cleanup (Agencourt AMPure XP Purification system (Beckman Coulter))

Remove Ampure beads from fridge. Make sure they are at room temperature (RT) before use.

- Vortex Ampure beads.
- Add 1V of Ampure beads for 1V of DNA (ie 100 μ l of beads for 100 μ l of DNA.)
- Vortex + pulse spin.
- Incubate for **5min** at RT.
- Move tubes to magnetic rack and wait for **2 to 5min**.
- Remove and discard supernatant without disturbing beads.

- Do not remove tubes from magnetic rack and add **200 µl of 70 % ethanol** without disturbing beads (use freshly made 70% EtOH to ensure accurate concentration.)
- Wait for **30s** (leave cap open.)
- Remove and discard supernatant without disturbing beads.
- Add again **200 µl of 70 % ethanol**.
- Wait for **30s** (leave cap open.)
- Remove and discard supernatant without disturbing beads.
- **Make sure to remove all traces of ethanol** (use a 10µl micropipette if necessary.)
- Dry for **5 min** (leave cap open.)
- Do not remove tubes from magnetic rack and add **25µl of buffer EB**.
- Close cap.
- Remove tubes from magnetic rack.
- Vortex + pulse spin.
- Wait for **2min**.
- Move strip back to magnetic rack and wait for **2 to 5min**.
- Transfer the **25µl** of DNA to new LoBind tubes.

9. Final quantification and equimolar pooling prior to sequencing

- Qubit Quantify 2µl of each.
- Check library profile on an Agilent Bioanalyzer with a High Sensitivity DNA Analysis Kit (1µl undiluted library).
- Perform KAPA quantification.
- Equimolar pooling of the 6 libraries.

Additional file 3

Adapters (Ultramer Oligos, TruGrade synthesis, Standard Desalting) were synthesized by IDT (Integrated DNA Technologies, Inc.) /5Phos/ = 5' Phosphorylation; * = Phosphorothioate Bond, F=forward, R=reverse).

Adapter were hybridized as follows:

25 μ M oligo preparation:

- Thaw 100 μ M oligos. Vortex and spin well.
- Pool each pair of oligos (F/R) in DNA LoBind tubes (1.5ml) as follows:

	Initial Concentration	Final Concentration
P1 F or P2 F	100 μ M	25 μ M
P1 R or P2 R	100 μ M	25 μ M
AB Buffer	10X	1X
Ultra Pure H2O		QS 100 μ l

- Vortex and spin well the oligo's pools and split each pool in tow PCR tubes (0.2ml)

Adapters hybridization:

- Place the PCR tubes in a thermocycler:

Program:		15 cycles (with -1.7 $^{\circ}$ C/cycle)	40 cycles (with -1 $^{\circ}$ C/cycle)	
Time	2min	1min	1min	∞
Temperature	95 $^{\circ}$ C	95 $^{\circ}$ C	69 $^{\circ}$ C	10 $^{\circ}$ C

- Vortex and spin well the tubes.
- Qubit quantify 2 μ l of diluted adapters (1/20e.)
- Adjust adapters concentration to 1.5 μ M if necessary and make aliquots.
- Store the aliquots at -20 $^{\circ}$ C.

Adapters (1.5µM) were stored in tube strips for usage comfort.

Analytical workflow – Step 1. Pre-processing of the data: from raw reads to raw UCEs

*The 2749 probes designed by Faircloth et al. (2015) were first assembled into a set of non-overlapping loci using Geneious. This set of reference UCE loci (N=1432) was then used to align sample-specific contigs obtained with CAP3. The reference UCEs are available in additional file 4.
